111

VOLUME 111

137877
25/2/16.

JULY to DECEMBER, 1915

MINING AND SCIENTIFIC PRESS
420 MARKET STREET SAN FRANCISCO, CALIFORNIA

INDEX

Page.

A

Absorption of cupels 481
Accidents, Constructing mine plants 693, 891
Metallurgical plants 785
Michigan mines 540
Mine 732
Ditto ..... J. W. D.... 953
Ditto ..... P. J. Donnelly.... 953
Ditto ..... W. E. Hopper.... 810
Ditto ..... F. J. Martin.... 621
Ditto ..... Paul M. Paine.... 953
Ditto ..... M. Smith.... 848
Ditto 713
More in metal than in coal mines 82
Prevention by the Steel Corporation ..... A. A. Willoughby.... 920
Quarries 137
Acetylene, by-products 975
Explosibility of 287
Gas 560
Gas, output of miners' lamp 518
Lamps in mines 560
Lamps, use of in British Columbia 544
Acid, and lower surface tension 311
Flotation at Anaconda 199
In leaching ore 384
Acidified water, wetting power of 388
Acidity of ore at Divisadero 205
Addicks, Lawrence ..... Leaching slime tailing.... 623
Adsorption 343
Advertisements, dull ..... Editorial.... 354
Ditto ..... P. B. McDonald.... 618
Advertising, psychology of ..... Editorial.... 822
Ditto ..... P. B. McDonald.... 226
Publicity and ..... Editorial.... 467
Ditto ..... P. B. M.... 75
After the War ..... Editorial.... 54
Agate and onyx 766
Agitation, laboratory tank 780
Treatment of concentrate 480
Agricola on mine speculation 513
Air and oil in flotation ..... Editorial.... 342, 829
Blasts 615
Blasts on the Rand 212, 525
Compressing plant at Balboa 249
Compressor efficiency 287
Driven tools, care of 306
Feed hammer-drill for driving ..... Frederick W. Copeland.... 802
For burning powdered coal 639
Froth flotation, The M. S.—Miami suit 583, 701
Hydraulic compression of ..... A. E. Chodzko.... 233
In cyanidation 89
In flotation, the natural medium 431
In liquids 429
In Miami flotation process 588
Pipes, canvas in mines 287
Receivers, attention to 602
Ajo mines, progress at ..... Editorial.... 867
Alaska 2
Gold production since 1867 225
Minerals at the Exposition 407
Timber resources 294
Tin in 757
Telovana district 328
Alaskan affair, The ..... Editorial.... 816
Alaska Gastineau mill, concentration ratio at 212
Mill and Perseverance mine ..... Robert S. Lewis.... 397
Production 218
Alaska Gold Mines Co. ..... Editorial.... 768, 790
And Alaska-Juneau M. Co. 916
Production 153
Alaska-Juneau M. Co., contracts for $158,864 machinery 874
Mill 682
Alaska Mexican Gold Mining Co., company report 111
Alaska Treadwell Gold Mining Co., accident at ..... I. 73
Club 308
Company report 111
Alaska United Gold Mining Co., company report 111
Alaskite intrusions 556
Porphyry at Iron Mountain 634
Alberta oilfields 106
Alkalinity 80
Allen, Carl A. ..... Mining engineer and prospector.... 807
Alloys in engineering construction 538
Alluvial sampling, relative error in ..... R. H. Elliott.... 465
Altitude and gas-engines ..... D. W. Brunton, J. Parke Channing, H. H. Clark, and A. T. Kasley.... 733
Effect on gas engines 639
Effect on mine-rescue apparatus 713
Alum in water-filtration plants 560
Alumina in earth 602
Aluminum 415, 501
Bronze 558
Increased use of 575
Powdered 935
Precipitation at mill of Butters Divisadero Co. ..... E. M. Hamilton and P. H. Crawford.... 387
Precipitation cost of 390
Precipitation, history of 387

Page.

Aluminum precipitation, reactions in 387
Production of U. S. 538
Reduction processes 287
Soldering composition for 249
State of market, every week.
v. Copper 915
Alunite in New South Wales 391
In Utah 16
Amalgamated Zinc (De Bavay's), Ltd., company report.... 874
Amalgamation as a consumer of quicksilver 409
At Big Pine mill 320
At Homestake 88
In mills 130
Of silver ores 211
Tailing, recovery of mercury from.... E. B. Thornhill.... 211
Amateur miner, the ..... Editorial.... 154
Ditto ..... Ernest G. Locke.... 426
Ditto ..... Charles P. Richardson.... 505
Amateurs, prospectors, and engineers ..... Editorial.... 503
Ditto ..... Leverett S. Ropes.... 880
American and European zinc smelters compared 510
Engineers on Rand 968
Potash ..... Editorial.... 805
American Association for the Advancement of Science 147
American Association of Engineers 576
Ditto ..... F. H. Newell, P. B. McDonald.... 731
American Institute of Electrical Engineers and International Engineering Congress 379
American Institute of Mining Engineers and International Engineering Congress 379
Meeting at San Francisco 311, 462
American Mining Congress ..... Editorial.... 423
American Smelting & Refining Co., profits 114
American Society of Civil Engineers, and International Engineering Congress 379
American Society of Mechanical Engineers and International Engineering Congress 379
American Vanadium Co., operations of 930
Amur, dredging on the ..... K. I. Hlebnikoff.... 283
Anaconda Copper Mining Co., accident record 176
And Michigan output 527
And zinc 950
Flotation at Washoe Reduction Works. ..... E. P. Mathewson.... 311
Improvements at 51
Analysis of Tonopah Belmont concentrate 431
And gold mines in Africa 710
Anodes in electrolytic precipitation 742
Anti-Debris Association, defunct 306
Antimonial lead 22
Antimony 415, 947
And arsenic ..... Editorial.... 114
Bolivia 772
California 33, 341
China 53
Fairbanks 489, 980
Gold ores, S. D. 564
In ammunition 341
Nevada 334
Ore, prices for, every issue in last three months.
Penta-sulphide 213
Apex litigation at Butte 754
Rights in Rhodesia 843
Apparatus for quicksilver analysis 663
Application of efficiency principles.... Fred H. Rindge, Jr.... 476
Applied geology ..... Editorial.... 729
Argentina, copper discovery in 232
Notes on ..... L. D. Ricketts.... 926
Arizona and modern mining 862
Gold Road district 21
Metal production of, 1911 183
Mines, taxation value of 143
Mining in ..... Charles F. Willis.... 95, 246, 751
Molybdenite in 938
Quicksilver in 938
Strike ..... Editorial.... 695
Ditto ..... Walter Douglas.... 771
Arkansas, zinc mining in 792, 867
Arsenic and antimony ..... Editorial.... 114
Production of U. S. 284
Asbestos, Arizona 818, 981
California 767
Chrysotile ..... F. H. Mason.... 774
Quebec mines, strike at 718
Quebec production 353
Ash in Alaska, volcanic 531
Asphalt in Philippines 293
Assay charges at U. S. offices 606
Furnaces, wood fuel for 227
Of base-metal ores for sale ..... J. J. Bristol.... 392
Of ore containing metallics ..... George L. Heath.... 39
Removal of selenium and tellurium in copper bullion ..... G. L. Sheldon.... 161
Assayers and their ways 628
Assaying at the Boss mine, platinum ..... Frank A. Crampton.... 221
Ditto ..... Thomas T. Read.... 269
Associated Northern mine, diamond-drilling at 361
Atolia, California 565, 850
Austin, L. S. ..... Recovery and use of thallium.... 930

Page.

Austin, W. Lawrence ..... Big business.... 117
Ditto ..... Leaching copper ore.... 199
Australia, copper not coming to America 615
Dredging in 796
Flotation in ..... Charles S. Galbraith.... 83, 731
Ditto ..... Edward H. Shackell.... 829
Gold discovery in 282
Gold output 678
Lead disposal 895
Metal business 978
Metal conditions 214
Metal Exchange created 303
Metal Exchange ..... Editorial.... 654
Metal sale 502
Metal trade ..... Editorial.... 36
Mints, refining gold at 137
Zinc exports 153
Zinc smelting 166
Automatic skips v. belt-elevators 593
Automobiles bought by Americans 615
Awaruite, composition of 474

B

Back-geared motors, work of 602
Baggaley flue-dust process 443
Bain, H. Foster, for U. S. Bureau of Mines 225
Ditto, lectures in Cornwall 501
Bains, Jr., Thomas M. . Electrical theory of flotation.... 821, 883
..... 97, 829
Ball-bearings 879
Ball-mill, an early ..... W. C. Ralston.... 7
Ditto, Marcy 7
Ball-mills and rolls v. stamps ..... Editorial.... 576
..... 58
Baltimorite 928
Bancroft, George J. ..... Mining in Colorado.... 55, 554, 750, 928
Bancroft, Howland . . Geology of the Gold Road district.... 21
Banking in Canada 887
Barnes-King-Kendall suit finished 685
Barrett, L. A. ..... Timber on mining claims.... 158
Batopilas Mining Co., report 874
Bausch & Lomb Optical Co. at the P. P. I. E. 261
Bauxite production of U. S. 538
Bawdwin mines metal output 843
Becker, Clyde M. ..... The engineer as a mine operator.... 619
Belt-elevators v. automatic skips 593
Belting at the Exposition 192
Ditto, used in 177
Efficiency 97
Link 137
Belts, leather 97
Tension of 485
v. motors 22
Bentonite 486
Big Business ..... Editorial.... 35
Ditto ..... W. L. Austin.... 117
Ditto ..... W. H. Shockley.... 425
Big Four Exploration Co., Utah, Mill of the ..... L. O. Howard.... 471
Big Pine, Manhattan, Treatment at the ..... P. J. Quinn.... 320
Billyard, John R. H. H. ..... Efficiency engineering in mines 620
Bishop Creek mining 332
Bismuth ..... Editorial.... 4
Black Oak mine, Cal., developments 906
Black sands 698
Blake-Morscher separator 927
Blast, A huge 855
Blast-furnace gases in silver-lead smelting 94
Slag 97
Blasting in an iron mine, System of 886
Blende, derivation of 935
Block, James A. ..... Why is Flotation?.... 659
Blomfield, A. L. ..... Classification and fine grinding.... 919
Blue powder from zinc smelting 511
Blyth, W. B. ..... Precipitating action of carbon in cyanide solutions 828
Boiler-plugs, Fusible-tin 249
Bolivia and Peru, taxes 767
Gold mining in ..... G. W. Wepfer.... 38
Miners, contract for tin ores between European smelters and 175
Potosi tin-mining district. . . Francis Church Lincoln.... 127
Some notes on 736
Bombs 558
Borax glass for welding metals 600
In California 50
In Chile and U. S. 210
Production in U. S. 205
Boring holes in rubber 58
Boss mine, Platinum assaying at the ..... Frank A. Crampton.... 231
Ditto ..... Thomas T. Read.... 269
Boston letter 610, 790
Boston Creek gold area, Ontario 680
Bowie, C. P. ..... The Round Lake mine.... 529
Braden Copper Co. mill, Chile, the 923
Mine, ore reserve of the 323
"Teniente Topics" New publication 265
Bradford, Leslie, flotation patent 688
Bradley, G. O. ..... Course-crushing plant of 1000 tons capacity 592
Bradley W. A. and Tuolumne 951
Brakpan mine 285
Brass and bronze 558
Definition of 131
Brayton, Corey C. ..... Who owns a report? 920
Brazilian manganese ore 818
Mining titles 520
Bretherton, S. E. ..... The waste of zinc 118
Brick production of U. S. 212
Brinsmade, R. B. .. Natural taxation of mineral land 671
Briquettes 94
Bristol, J. J. ..... Assay of ore containing metallics 39
Britannia copper mine, the 553

Page.

British Columbia mining 329
Ore mined in 796
Zinc 147
British Columbia Copper Co., new plants 570
Smelter 257
Broadwater Mills Co. at Park City 471
Broad, J. M. ..... Sinking the Woodbury shaft, Mich.... 734
..... 84, 91
Broken Hill, flotation at ..... Editorial.... 344
Ditto ..... Flotation at the Central mine. . . . James Hebbard.... 347
Broken Hill Proprietary Co., report 801
Broken Hill South Silver Mining Co., company report 497
Brunton, D. W. ..... Technical reminiscences.... 811
Bubbles 624
Ditto ..... Editorial.... 578
And surface tension 583
Cost me hard labor and more bubbles, my first introduction to flotation ..... Ben S. Revett.... 590
In flotation 514
Bucket-elevator, cost of operating 507
Bucyrus drag-line excavator at Iditarod 452
Bulkhead, underground 786
Bullion, sampling base ..... F. D. Weeks.... 310
Bunker Hill & Sullivan lead smelter 502
Bureau of Mines, U. S. 74
Bureau, State Mining, Cal. 75
Burgess, John A. ..... Study of mining geology.... 858
Burma Corporation 864
Burton, C. S. ..... Speculation in mines.... 37
Business, Big ..... Editorial.... 35
Ditto ..... W. L. Austin.... 117
Ditto ..... W. H. Shockley.... 425
Butte, Montana 754, 976
Metal output of 354
Butte & Superior Copper Co., company report 339, 840
Flotation machine 585
Misfit name 303
Profits 265
Split by Elm Orlu Mining Co. 685
Butters, Charles, and the new metallurgy ..... An interview ..... T. A. Rickard.... 273
Ditto ..... Flotation of gold ore.... 954
Ditto, and Clennell, J. E. ..... Cyanide treatment of flotation concentrate 778
Butters Divisadero Co., aluminum precipitation at the mill of the ..... E. M. Hamilton and P. H. Crawford.... 387
Buying mining supplies ..... P. B. McDonald.... 198b

C

Cadger, definition of 327
Cage and skip, changing 547
Calaveras Copper mine 184
Calcite in pocket deposits 447
Calcium carbide, temperature of manufacture 249
Triphosphate in poultry food 353
Calc-schist at Kalgoorlie 240
California contribution of wealth to the world 468
Dredging in ..... Charles G. Yale.... 483
First-aid teams 527
Gold boom imminent? 378
Gold output up to date 310
Gold yield in 1914 367
Industrial Accident Commission 201, 298
Iron industry, possibilities of 531
Mineral production in 1914 607
Minerals at the Exposition 59
Mining in ..... Charles G. Yale.... 52
Oilfield supervision 225
Pocket mining in 332
State Mining Bureau 525
Stocks in Boston, feeling of 640
Callow, J. M. ..... Notes on flotation.... 849
Ditto ..... Flotation machine.... 9, 311
Calumet & Hecla Mining Co. management 120
Profits 982
Camp Bird, Limited 680
Quarterly report 333
Cam-shafts, thermit-welding of 447
Canada, a trip through eastern ..... P. B. McDonald.... 775
Canadian banking system 887
Capital and labor ..... Editorial.... 654
Car, new mine 988
Carat, and Frank Rowley 345
Carbide lamps in mines 518
Carbon in cyanide solutions, precipitating action of ..... W. B. Blyth.... 828
Ditto ..... O. C. Ralston.... 77
In Kalgoorlie ores 239
In steel 213
Carbonic acid gas in flotation 384
Carborundum lining for melting furnaces 327
Career, the story of a ..... Editorial.... 952
Carelessness underground 810
Carnotite claims in Utah 666
Ores for radium, treatment of 974
Carpenter, Jay A. ..... Precipitation with zinc-thread.... 888
Ditto ..... Work at West End mill.... 284
Carr drill-bit 700
Carranza, Venustiano, Obregon, Villa, and Zapata 463
Photograph 610
Recognition of 577
Cathodes in electrolytic precipitation 748
Cattermole flotation apparatus 703
Flotation process 348
Sulman and Picard patent 581
Caucasus, manganese in 54
Cause of misfires 358
Caustic soda or potash in aluminum precipitation 387
Cement, lime in Portland 526
Central American Mines Co., company report 651
Centrifugal pumps at Leadville 356
Cerro Gordo zinc output 368

Page.
Chain-driven tube-mills, cost of chains 483
Chalk, capacity for holding water 410
Chapman, G. A., flotation work by 348
Charles Butters and the new metallurgy
An interview ..... T. A. Rickard.... 273
Chemical labels 363
Chemistry, colloidal ..... Clifford Richardson.... 48
Of leaching ores 199
Chert in iron ores 602
Cheyenne, Wyoming 450
Chiksan concession, prospecting on the
Charles W. De Witt.... 896
Chiksan Mining Co., dredge of 842
Chile, borax 210
Some notes on 788
Chile Copper Company 1
Chilean mill practice 708
China, copper in 741
Mining in 443
Oil in 248
Trade openings in 665
Wah Chang mines ..... H. T. Liang.... 53
Chino Copper Co., company report 257, 800
Chisana, Alaska, prospects of 412
Chlorination at Park City 16
Some history 274
Chlorine refining of gold 137
Chodzko, A. E. ..... Hydraulic compression of air.... 233
Chrysotile-asbestos ..... F. H. Mason.... 774
Chuquicamata 1, 49
Churn-drill holes for ventilation 213
Churn-drilling checked by underground work 249
Cost 249
Costs at Bisbee 294
Cinnabar in Western Nevada 536
Ore treated in U. S. 483
Claims in national forests, mining ..... H. W. Reed.... 229
Surveyed in Utah 788
Clark, Allan J. ..... Notes on Homestake metallurgy.... 8
Classification and fine grinding ..... A. L. Blomfield.... 919
Ditto ..... A. E. Drucker.... 581
Of technical literature ..... W. P. Cutter.... 6
Classifier, Dorr 7
Clay, China, industry of Cornwall 566
Products of U. S. 567
Clennell, J. E., and Butters, Charles ..... Cyanide treatment of flotation concentrate 778
Cleveland-Cliffs Iron Co., mining school 660
Shaft, work of 859
Work in its Morris-Lloyd mine 885
Cleveland-Knowles separator 928
Clevenger, G. H. ..... Electrolytic precipitation of gold, silver, and copper from cyanide solutions 742
Clifton, Arizona, labor troubles 539
Coagulation in flotation 516
Coal for Fairbanks, Alaska 666
Mine explosion tests 527
Mining employs many men 628
Mining in Mexico 610
Powdered, air for 639
Production of U. S. 508
Prospecting, value of fossils in 679
Used for domestic purposes, quantity of 679
Coarse-crushing plant of 1000 tons capacity
G. O. Bradley.... 592
Cobalt district developments 718
District, dividends 985
Cobalt for coins 915
Hardness of 287
For electro-plating 753
Ore in Canada 469
Oxide, notes on 560
Coeur d'Alene dividends 255
Metal production 362
Metal production in 1914 296
Mining region 713
Region, Idaho, map of 684
Coghill, Will H. ..... Surface tension.... 543
Ditto ..... Ferrous and ferric iron in cyaniding.... 598
Coins, various 560
Cole flotation machine 9
Collins, Edgar A. ..... Pumping at the Commonwealth mine, Arizona 786
Collins, George E. ..... Everson.... 881
Collins, H. F. ..... Concentration of gold in bottoms in the converter 132
Colloid, definition of 556
Colloidal chemistry ..... Clifford Richardson.... 48
Solutions 624
Colombia, platinum production 377
Colorado, early days in ..... Editorial.... 804
Geology of Gilpin county 453
Hammer-drilling in ..... E. G. Snedaker.... 669
Mining in ..... George J. Bancroft.... 55, 554, 750, 926
Colorado Fuel & Iron Co. 532
Combustion 363, 507
Definition of 291
Flameless 480
Of gases in boiler furnaces 409
Commerce of U. S. 540
Commission, Ontario Nickel ..... W. G. Miller.... 426
Commonwealth mine, pumping at the
Edgar A. Collins.... 786
Companies operating in Oklahoma 795
Company Reports:
Alaska Mexican Gold Mining Co. 111
Alaska Treadwell Gold Mining Co. 111
Alaska United Gold Mining Co. 111
Amalgamated Zinc (De Bavay's) Ltd. 874
Batopilas Mining Co. 874
Broken Hill Proprietary Co. 801
Broken Hill South Silver Mining Co. 497
Butte & Superior Copper Co. 329, 849
Central American Mines Co. 651
Chino Copper Co. 800
Consolidated Interstate-Callahan Mining Co. 339, 651, 800

Page.
Company Reports:
Esperanza, Ltd. 66
Granby Consolidated Mining, Smelting, & Power Co. 800
Jumbo Extension Mining Co. 197, 801
Kyshtim Corporation 695
Lake View & Oroya Exploration, Ltd. 912
Magma Copper Co. 331
Mt. Morgan Gold Mining Co. 339
National Railways of Mexico 871
Natomas Company of California 840
Nevada Consolidated Copper Co. 800
Nevada Wonder Mining Co. 912
Oriental Consolidated Mining Co. 651
Pacific Gas & Electric Co. 219
Ray Consolidated Copper Co. 800
Shannon Copper Co. 62
Tomboy Gold Mines Co., Ltd. 800
Utah Copper Co. 800
Compass for surveying drill-holes 857
Compression of air, hydraulic ..... A. E. Chodzko.... 235
Computer, new 5-place 340
Comstock developments 116
'Concentrate' and 'Ore' 213
Concentrate: Then and now ..... T. H. Oxnam, Jr.... 308
Cyanide treatment of flotation
Charles Butters and J. E. Clennell.... 778
Method of sampling mill pulp 738
Concentrating at Juneau 190
Concentration at the Tonopah-Belmont 363, 431
Of copper ore by flotation ..... Editorial.... 804
Of gold in bottoms in the converter ..... H. F. Collins.... 132
Of zinc ore in Wisconsin 929
Ratio at Gastineau mill 213
Then and now ..... John Ebenstein.... 198a
Upside down, flotation 428
Concerning a claim ..... Editorial.... 951
Rock-drills ..... P. B. McDonald.... 208
Talk ..... Editorial.... 769
Concrete floors in mills 324
Structures, paints for 237
Condenser water, cooling system for 882
Conditions in Sonora 80
Congress, American Mining 423
Congress, U. S., mining bills in 902
Consolidated Interstate-Callahan Mining Co., company report 651, 800
Consumption of zinc and alkali at West End mill 889
Continuous counter-current decantation cyanide-plant at Rochester 317
Co-operation and individualism ..... Editorial.... 846
Co-operative experiments in production a failure 377
Contact-deposits, origin of 363
Contract for tin ores between European smelters and Bolivian miners 175
Converter, concentration of gold in bottoms in the
H. F. Collins.... 132
Converting blast-furnace flue-dust 443
Coorongite 287
Copeland, Frederick W. ..... Air-feed hammer-drill for driving 802
Copper bullion assays, removal of selenium and tellurium in ..... Geo. L. Heath.... 161
Cost of producing in Alaska 377
Discovery in Argentina 232
Electrolysis, precipitation of ..... R. R. Goodrich.... 210
Exports 693
Export embargo 113
For bull-rings 935
For Germany 915
From Central Africa 225
Import duty on in Russia 695
In China 741
In Cyprus 693
In Germany 225
In iron manufacture 137
In Michigan ores 773
In Serbia 727
Lake, price of 2
Mass, extraction of 679
Matte, handling leady ..... H. F. Easter.... 484
Mining in Russia 140
Ore, by flotation, concentration of ..... Editorial.... 304
Ore from Alaska via Panama 273
Ore leaching 485
Ditto ..... W. Lawrence Austin.... 199
Output of Bonanza mine, Alaska 331
Output of Michigan mines 105
Prices and market conditions, every week.
Production of Central Africa 364
Production of Michigan mines 185, 256, 454, 608
Production of Peru 198a
Production of Russia 96
Purity of Lake 177
Shares, dividend basis of 198a
Shares, rise in 3
Used in warfare 653
Used per capita in the world 829
Uses of in Turkey 882
v. Aluminum 915
Copper Queen mine, ventilation of 152
Corinthian North mine, treatment at 815
Cornish miner in America ..... P. B. McDonald.... 470
Cornwall, mining in 566
Tehidy estate sold 654
Tin situation in 716
Corphalie Zinc Co., litigation 314
Corrections ..... F. H. Mason.... 507
Corundum 583
Cost and efficiency ..... A. E. Jacobs.... 197
Costs at Braden Mill 924
Assays at Oriental Consolidated 713
Britannia mine, B. C. 553
Chain repairs on tube-mills 483
Constructing Engels mill 170
Constructing the Tonopah-Belmont mill 324
Diamond-drilling at Le Roi No. 2 mine 598

Page.

Costs:
Disposal of residue at Wasp No. 2 mine ... 475
Drilling underground ... 672
Drill-steel ... 58
Elevating pulp at Tonopah-Belmont ... 597
Erecting coarse-crushing plant ... 598
Filing at Washington, D. C. ... 362
Flotation ... 125, 853
Flotation at Broken Hill ... 137
Flumes in the Klondike ... 322
Goldfield Consolidated ... 598
Grouting a shaft ... 862
Homestake mills ... 88
Jumbo Extension ... 427
Korea, plant construction ... A. E. Drucker ... 887

The Flotation Process—

Do you know what it is, how it operates, what it will accomplish? If you are not completely posted, here is a chance to get sound, comprehensive information.

On or about March 1, 1916, the MINING and Scientific PRESS will have ready for distribution A NEW BOOK, edited by T. A. Rickard, ON FLOTATION—the epoch-making process.

The editor has revised the many notable articles that have been contributed to the MINING and Scientific PRESS by recognized authorities and has amplified and arranged them in logical sequence, thus producing by far the best and most illuminating presentation of The Flotation Process that has ever been published.

It is not generally understood that the flotation of metallic sulphides and of the precious metals can be effected by three essentially different methods: (1) Surface suspension; (2) Bulk oil buoyancy; (3) Frothing.

These involve machines of different character but generally of simple design. All of these features will be reviewed, as well as many typical instances of the practical operation of the process on ores of different character. Full details will be given of the apparatus used for experimentation.

The price of the book, more than 250 pages and cloth bound, is $2, postage prepaid. But there is a less expensive way to get it.

Every man engaged in mining and metallurgical work needs this great book. Read this offer—

For $4 —just four dollars, you can get this book and an entire year (52 issues) of MINING and Scientific PRESS. And consider that some of the foremost authorities of the mining world are contributors. Winchell, Leggett, Farish, Beatty, Bradley, Caetani, DeKalb, Garrison, Probert, Shockley, Purington, and many other leaders in their respective fields use the MINING and Scientific PRESS as a medium for the expression of their experience.

SEND THIS COUPON TODAY

Then, too, T. A. Rickard is editor. There is, perhaps, no other mining engineer today whose writings are so alive with knowledge of his field and with the experience and facility of expression that make interesting as well as instructive reading.

This new book is now on the press and will be ready March 1, 1916. Send in your order now so you will be one of the first to receive a copy. Orders will be filled in the order they are received.

MINING and Scientific PRESS is published in the heart of the mining country. It is *first* to hear news and to publish it. A staff of trained correspondents covers the field. Its resources for news gathering are superb. The standard of importance in the special articles published during the past year will be maintained in the next.

You need MINING and Scientific PRESS. When you consider that you can have it and this great book as well, you should accept this offer.

Send us the coupon and four dollars. Your subscription to MINING and Scientific PRESS will start at once. Fair enough, use the coupon—NOW.

EDITORIAL

T. A. RICKARD - - - - Editor THOMAS T. READ - Associate Editor

JULY THE FOURTH is a great day in the mining communities of the West. It is celebrated in a variety of ways. This year more interest than ever has been shown in preparation for drilling contests, first-aid exhibitions, and mine-rescue demonstrations. These, apart from the element of spectacular sport, in itself agreeable, are educative and informing.

HUERTA says that "it is easier to crush cement than to crush a Mexican revolution." It certainly is better to make a durable building material than to add one more to the several 'revolutions' already in progress. Mexico needs a constructive building material that will give it a government reinforced to resist the ambitions of unscrupulous adventurers.

IN the making of an 18-lb. shrapnel shell the consumption of metal is as follows: copper, 4.04; zinc, 1.87; lead, 6.93; antimony, 0.99 pounds. The larger shells require more brass, that is, more copper and zinc. Estimating the European orders already placed in this country at 25,000,000 shells, this involves the consumption of 101,000,000 pounds of copper, 46,750,000 of zinc, 173,250,000 of lead, and 24,750,000 pounds of antimony.

SPEAKING of zinc, this is imported into South Africa through Delagoa Bay. Most of it used to come from Germany; now most of it is imported from the United States. During the five months August to December 1913, all of it, namely 1758 tons, came from Germany. In the same period of 1914 only 402 tons came from there, while 2058 tons arrived from the United States. Now presumably all of the supply, 2500 tons, comes from here.

ACCORDING to the Bureau of Foreign and Domestic Commerce, the exports of spelter in pigs, bars, plates, and sheets was 120,149 pounds in April last year, as against 17,683,173 pounds in the same month this year. Another comparison is based on the ten months covering the period of war, thus:

Exports of zinc or spelter.	Pounds.
In 10 months ending April 1915	222,478,162
In 10 months ending April 1914	3,243,418
In 10 months ending April 1913	4,997,680

These statistics are eloquent.

STANFORD is to be congratulated on its new professor of geology, Mr. Bailey Willis, who succeeds Mr. John C. Branner, now president of the University. Mr. Willis is known to mining engineers for his work on the Geological Survey and his scientific investigations in China. Recently he has been serving as consulting geologist to the Argentine government. Thus, like Dr. Branner, he understands South American conditions and is well fitted to further the *rapprochement* between the two Americas by preparing students for geological exploration in the southern continent.

COPPER SHARES have not risen in proportion to the price of the metal. On a 20½-cent quotation their earnings ought to increase by 50 to 60% as compared with copper at 16 cents, which was the price three months ago. This means, in the first place, that the benefit of the higher price does not come into operation at once, as copper is sold for forward delivery, and it also suggests that the public is waiting to see if the enhanced quotations persist. We believe they will.

THE CHUQUICAMATA mine, owned by the Chile Copper Company, is destined to put even the Rio Tinto and Calumet & Hecla in the background. Mr. Pope Yeatman estimates the ore assured at 303,300,000 tons averaging 2.23%, and he regards it as certain that the tonnage will reach 400,000,000 "without by any means limiting still further possibilities." The mill, of 10,000 tons daily capacity, was started on May 18 and is expecting to be working to full capacity by the end of the current year. It is intended to enlarge the plant to a capacity of 30,000 tons per day, not per week or per month. The estimate of cost, treating 10,000 tons daily, is $2.10 per ton on a 2% ore. Copper is to be delivered in Europe for 6 cents per pound. Thus, by the beginning of 1916, this mine will be producing at the rate of 75 to 100 million pounds of refined copper per annum.

MISFORTUNES of a serious kind have befallen the Treadwell group of mines, on Douglas island, Alaska. On June 19, the main shaft of the hoisting-engine at the Central shaft broke. This, of course, is a heavy piece of hammered steel, weighing fully 30 tons, so that it cannot be replaced in less than two months, although it could be repaired by the use of thermit at Seattle. Through the Central shaft is hoisted the ore that feeds the Treadwell, Mexican, and 700-Ft. mills, but not the Ready Bullion. A far worse mishap occurred on June 15 when the ground on the south orebody of the Treadwell caved from surface to the 1400-ft. level and at the same time the north orebody caved to the 900-ft. level. This collapse of ground is due probably to the drawing of the caved ore from the stopes below the 750-ft. level. Additional caving ensued, affecting the main pillar between the No. 2 and No. 9 open-cuts. Apart from the interruption to production, this caving

must entail serious loss by rendering unavailable a large tonnage of ore. The two misfortunes have caused a nearly complete cessation of milling, for the present, but the use of the Mexican shaft should enable the Mexican and 700-Ft. mills to resume work, while the Treadwell, we presume, will have to reorganize the No. 2 shaft, a task requiring two or three weeks. Mr. J. H. Mackenzie, in the absence of Mr. F. W. Bradley, now at Honolulu recovering from a recent illness, has gone to Treadwell to consult with the manager, Mr. Philip R. Bradley.

LAKE COPPER has for many years commanded a premium over electrolytic. The Calumet & Hecla and Quincy copper is free from arsenic and other deleterious impurities that render copper less ductile and decrease its electric conductivity. When the electrolytic copper-refining process was first developed the copper made by it was more impure than the Lake product. The process has been so perfected that this condition no longer obtains; nevertheless, many consumers still specify Lake copper and prefer to pay the premium for metal they know is pure rather than take a chance with metal that has been purified. Meanwhile the arsenic content of the Lake ores is increasing, and a short while ago the Calumet & Hecla built an electrolytic refinery to handle part of its output. Some of the mines, such as the Mohawk, Wolverine, Baltic, Champion, and Trimountain, produce copper that contains arsenic in sufficient amount to make it desirable for fabricating seamless tubes, sheets for boilers, locomotive fire-boxes, and other uses for which hard copper is desirable.

ALASKA is indebted to the Secretary of the Interior, Mr. Franklin K. Lane, for publishing a clear statement in regard to the need for a simpler administration of the great northern territory. His statement appears in *The New Republic*, a periodical of growing influence. The President has spoken of Alaska's resources and the development of them in sympathetic terms. They "must be used, but not destroyed or wasted: used, but not monopolized under any narrow idea of individual rights as against the abiding interest of communities." That means, among other things, that the mineral resources of a vast region are neither to be monopolized by adventurous individuals and venturesome corporations nor bound in impotence and unproductiveness by departmental red tape and administrative delays. Alaska has suffered quite as much from one set of evils as the other. The "abiding interest" of neither the territory itself nor the United States is served by irritating restrictions upon intelligent initiative and honest development. Mr. Lane recognizes this, and it is of good augury for Alaska, since he is in a position to give effect to his ideas. He advocates the creation of a single Development Board, appointed by the President and confirmed by the Senate. This Board, while responsible to the Secretary of the Interior, should do the work now scattered and duplicated among the General Land Office, Forest Service, Road Commission, Bureau of Mines, and Bureau of Education, besides the Secretary of the Interior. If some such centralization and simplification of authority could be effected, so as to end the wearisome delays in obtaining title to homestead and mining locations, and in starting any sort of new work in a region awaiting sane exploitation, the people of the North will be ready to exclaim: "For this relief, much thanks."

A Rare Chance

From time to time we hear that financial corporations or exploration companies find great difficulty in their search for new business, that is, promising mines at reasonable prices. We realize that a good mine at a fair price is a rare bird. It may be suggested that the search for this desideratum has been so lively and so thorough that the chances of a kill are poorer than they used to be. Perhaps. But it is equally true that the criteria for the purchase of a mine are more exacting than heretofore. People, especially the clever people that control these mine-searching expeditions, know more than formerly; they will not buy a "pig in a poke"; they refuse to put their money down until a careful investigation has been made by competent engineers. Moreover, even the public has gained wisdom in these matters—not a great deal, it may be, but enough to know a brick from a bar of gold. Therefore, it is no longer easy to "pass the buck," that is, to unload a disappointing mine upon the unwary. Undoubtedly the whole business is no longer on the amateur footing that it used to be. If, in consequence, money is not made in chunks, at least it is not lost with the inconsequence of a drunken sailor. However, we shall not try to discuss so broad a subject on this occasion; our purpose is to touch on one particular aspect of it. With knowledge has come caution, sometimes of a paralyzing kind. Risk is inherent in a speculative business like mining. It is necessary to ascertain the facts as carefully as possible and then go ahead, not collect facts and then stare at them helplessly. Yet this has been done on more than one occasion when the chances of a lifetime have been offered. We quote one case, on first-hand information. A Columbia student, taking a holiday in Canada, happens to go to Haileybury at the time of the Cobalt boom. The little hotel is crowded, but he is fortunate enough to get a bed. After dinner, sitting in the lobby, he enters into conversation with an elderly gentleman, of kindly disposition, but lacking a bed. He offers his own, saying that he is used to roughing it and can sleep on the floor. The offer is accepted gratefully. Next day he is taken by the elderly gentleman, whom we will call Colonel Tompkins, on a tour of the new district. Later, in parting, he is invited to ask for a job when he has graduated from the School of Mines. In the course of events, he does so and is sent as a scout to Nevada. He goes to Goldfield. There he meets another Columbia graduate (No. 2) who has just finished a sampling and mapping of the Mohawk mine, then a wonderful prospect. No. 2 tells him it is a good thing and that an option is obtainable. They examine the evidence. No. 1 gets an option on 351,000 shares, that is, the control, at $2 per

share. Thereupon he telegraphs to the Colonel, urging him, as representative of a well-known corporation, to take action promptly. When the telegram arrives, the quidnuncs at headquarters decide that it is absurd to think of paying $702,000 for a mere prospect. They do not even take the trouble to make an examination. This was in June 1906. A few months later the shares of that mine sold at $20 per share, because one of the big bonanzas of the world had been uncovered. The Mohawk needs no encomium now; it has been worked out for a yield of millions and is the nucleus of a big consolidation, still productive. The moral is plain; don't send a scout unless you can trust his report. Moreover, if you are in the business, never lose a chance merely to save the expense of an investigation. As James D. Hague said long ago: "Mines are like the saints, for many are called and few are chosen." The chosen wear a halo.

Flotation

This is a metallurgical subject of such commanding interest that we are glad to give our readers a critical description of one of its latest phases, in the form of an article on the experimental work preceding the construction of the Inspiration mill. Our contributor gives a particularly lucid account of the work done at this important copper mine in Arizona. In his case, we believe, the knowledge of the subject is supplemented by the ability to transfer that knowledge to others. We regret that the compliment must be impersonal, since the author of the article writes under the veil of anonymity. His foot-note makes humorous reference to the shyness of a preceding writer on the same subject. Indeed the metallurgic art of flotation at the present time is characterized by a great deal of mystery, due, of course, to patent litigation. The hearing of the case between Minerals Separation and the Miami copper company has been proceeding for eight weeks before Judge Bradford of the U. S. District Court at Wilmington, Delaware. Incidentally, we may mention that a special cinema apparatus was designed by the plaintiff to illustrate the operations involved, and, in order to do this effectively, it was necessary to take 120 photographs per second (as against the 10 or 12 taken in the ordinary moving picture) with an exposure of one ten-thousandth of a second. Whatever the decision, an appeal is certain. That appeal, we understand, will come before the very Court that gave such a sweeping decision in the Moore-Butters filter case. Strategy appears as useful in legal battles as in those of a more lethal arena. If Minerals Separation loses, we presume that the secrecy beclouding the rapid advance of this branch of metallurgy will be thickened, while if the major patents are sustained it may be that the proprietors will give information with some freedom. Assuredly it is altogether to the interest of the profession and the industry of mining that information of the kind given in the Inspiration article should be published. It injures nobody; it helps many. We hope that other members of the profession will avail themselves of the opportunity to do likewise.

Metal Prices

The trail of the Great War crosses all things human. It has left its traces on the metal trade. In the early days of the conflict, last year, quotations for the base metals suffered collapse. Even after a temporary recovery the effects lingered. In common with others we were led to appreciate the artificial character of a market that was in the hands of a group of metal-brokers, competing, it may be, among themselves as to the division of the profit, but united in fixing quotations that suited their books. This feature was helpful to the industry during the crisis last August, when the metal-selling agencies came to the rescue of the market by uniting in a refusal to sell copper at panicky prices. That much must be allowed in all fairness. But there is another aspect to which we must direct attention. In London, Melbourne, and New York, during the crisis, the same European names appeared behind the local brokerage houses and metal merchants. The combination was suggestive, if not suspicious. It boded ill for the mining industry that the sale of its metallic products should gravitate so nearly to one point, to what was practically one international or non-national group of speculators. We have made an effort to protect our own readers, at least, by changing the source of our metal quotations. It will interest the owners of mines to know that until recently the *Engineering and Mining Journal* and the Mining and Scientific Press both obtained their metal quotations from the same source, a source believed to be absolutely reliable, and *The Mining Magazine* obtained its quotations from the London correspondents of the same house, also believed to be absolutely reliable. No reason exists even now for suspecting that there was anything wrong, but the disclosures made at Adelaide in the Snow trial indicated to us that the New York firm and its affiliated London house were both members of a group of brokers that exercised an unhealthy dominance over the metal trade, a dominance that might easily be misused. Therefore we decided to safeguard our readers by obtaining quotations from a source wholly independent; in other words, to obtain not the metal-brokers' quotations but the consumers' prices. This we have done now for several weeks. The page entitled 'Eastern Metal Markets' and the telegraphic quotations given each week may be accepted as reliable to the utmost degree possible. We commend the study of them to those having in charge the sale of the metals produced by mines on this continent. We give as accurate an approximation as is possible of the actual prices that consumers are called upon to pay for the metal they purchase for use in their business. Such prices are called "approximate" because frequently there are deals put through at varying figures in the course of a single day, sometimes in the course of a single hour. Copper, for example is often quoted in certain trade publications, and therefrom in the daily and weekly press, at prices for which the metal cannot be bought, yet with them goes no explanation that the quotation is not for the consumer. The price is not real, for the metal cannot be had at the figure mentioned. Is it not absurd that when one sees a

price quoted and asks a seller: "Will you sell copper in any quantity at that figure?" he should answer "No." If the question is then asked "Will you tell me where I can get copper at that figure?" and again the answer is "No." Finally, "Is it possible for anyone to get copper at the figure quoted?" And the answer is still the same. Sometimes the selling agencies connected with producers will endeavor to encourage speculation by bulling prices. For instance, on a recent day the Wall Street papers that get their information from the big agencies said that producers were holding copper at 19 cents full terms for electrolytic, with some offerings at 18.875c., while a buyer for export stated that he could get copper in almost any quantity between 18.50 and 18.62½ full terms, or 30 days, delivered. In an intricate business such as that of metal-selling there are many ways that are dark and tricks that are not in vain. The operators of a small mine, and even those controlling the bigger ones, are rarely in a position to protect themselves. We offer them one measure of protection by giving them the prices that the consumers are paying for copper, lead, and zinc. On the earnestness of our effort to secure absolute trustworthiness of the figures we pledge our honor.

Bismuth

Bismuth is one of the metals that command a high price merely because they do not occur in abundance; the price of it is based on the demand and not on the cost of production, which is probably only one-eighth of the selling-price. Not uncommonly bismuth is found as native metal, as in the famous mining district of Schneeberg, in Saxony, and in other places in Bohemia and Saxony. It is also found in Chile, Bolivia, Sweden, Norway, and Australia, usually in association with ores of cobalt, nickel, silver, lead, zinc, and gold. Another important mineral frequently associated with the native metal is bismutite, the hydrous carbonate, and with it is often found bismuthinite, the sulphide. Bismite, the trioxide, is also the source of some bismuth; the three closely similar names being somewhat confusing. Tetradymite, the telluride, which looks like graphite, is also not uncommon. No bismuth is mined in this country, the entire domestic production is recovered as a by-product in the electrolytic refining of lead from the anode slime. The plant of the United States Smelting, Refining & Mining Co., at Grasselli, Indiana, and that of the American Smelting & Refining Co., at Omaha, yield 175,000 to 200,000 pounds of the metal yearly. Bismuth also occurs in copper ores, but most of it escapes through the stack in smelting. Blister copper sometimes contains as much as 25 lb. bismuth per ton, but, so far as we know, none is recovered from this source. About an equal amount is imported from Europe, chiefly from Germany, where the European and South American ores are treated, and from England, where ore from South America and Australia is reduced. The ore of the Suan mine, Korea, contains 1.7 lb. bismuth per ton. In Saxony the ores are first roasted, to free them from sulphur and arsenic, and are then smelted in crucibles with iron and charcoal, the bismuth thus reduced collecting on the bottom of the crucible. The metal may also be recovered in the wet way by treatment with hydrochloric acid, taking the bismuth into solution, from which it can be precipitated by dilution as the oxychloride. This must be redissolved and precipitated several times in order to free it from lead; it is then reduced to the metal by fusion with lime and charcoal. Gold and silver can be separated from the bismuth by the use of zinc, by the process used for de-silverizing lead. A great variety of methods have been employed in the metallurgy of bismuth; they are described in detail in Schnabel's 'Handbook of Metallurgy.'

Bismuth has a melting-point of 260° C., but it forms with other metal alloys of much lower melting-point. Thus Lipowitz's metal, consisting of 50% bismuth, 26.9% lead, 12.78% tin, and 10.4% cadmium, melts considerably below the boiling-point of water. In cooling from the molten state this alloy contracts after solidifying until a temperature of 100°F. is reached and then expands until 77°F. is reached, when it again contracts so that at 32°F. it has the same volume that it had at 115°F. This property of expanding on cooling is characteristic of bismuth alloys and makes them desirable for a number of purposes. Thus bismuth is added to the alloy from which stereotype plates are cast in order that a clear impression of the type may be taken. Soap-makers also make their molds from a bismuth alloy. Alloys of bismuth have been used as fusible safety-plugs for boilers, but the continued action of heat changes their melting-points, so that they cannot be relied upon. The ready fusibility of its alloys makes them useful as fuses in electrical construction, and considerable quantities of the metal are probably consumed in this way each year. It is also a component of the alloy used for silvering mirrors, and as no secondary metal is ever recovered in either of these two uses, this is a true consumption.

No large deposits of bismuth ores have been found in this country, but several small high-grade deposits are known. The Highland Mary mine, at Leadville, has produced some 15% bismuth ore; the Comstock mine, in the La Plata mountains, Colorado, has produced ore containing 18% bismuth; and the Indiana mine, near Ouray, also in Colorado, has produced small lots of ore containing 25% bismuth. It is interesting to note that to none of these mines was anything paid by the smelters for the bismuth content of the ore, but in fairness it should be added that probably none of the bismuth was recovered in smelting, because the use of electrolytic refining, in which the bismuth is saved, has only recently been adopted by the two plants mentioned. Presumably a fair price would now be paid for the bismuth content of ores, and there seems no reason why the domestic output should not increase sufficiently to take care of domestic consumption at least. It is generally believed in this country that the price of bismuth is strictly controlled by a European syndicate that boycotts any producer found guilty of selling below the established price. If this is the case, it becomes all the more desirable that domestic consumption should be supplied by our own producers.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more vaulable than casual compliment.

The Spelter Situation

The Editor:

Sir—When the terne mixture and copper are sold at prices less than that of spot spelter, it can truly be said that the metal market is decidedly out of joint and that the abnormal condition is not one having any degree of permanence. This mushroom growth is an unhealthy one and those who have become temporarily unbalanced by the recent pyrotechnics in the zinc trade and have abandoned former standards in the rating of metals may well consider their steps before treading upon what appears to be solid ground, but in reality is a quagmire. I do not mean by this that real zinc property today is an unsafe investment. However, the prospective investor should not in any way correlate the present spelter prices with the value of blende-producing properties, as some would ask us to do.

The European demand for munitions has created market conditions previously unknown in the spelter trade. To meet these exigencies, the smelter capacity of this country has been greatly taxed. Concentrate, or the immediate product of the mines, however, is to be had in abundance and until increased smelting facilities make possible the treatment of greatly increased tonnage there will not be any such market for the mine-product as many producers believe there rightly should be. The proposed investigation of a 'zinc trust,' which does not and never has existed, by the Attorney-General of Missouri is a misguided movement on the part of the zinc miners to ascertain the reason for the high price of spelter and the relative low price of concentrate. The formation of an association of the zinc producers of Utah and Nevada, as discussed in your issue of June 5, is a well-purposed movement to better the status of the producer, but it seems almost equally inexpedient. While I am not cognizant of the plans of this organization, although wishing them well, I see but little hope of improving their present position without great and unwarranted expenditures in smelter construction. It would be no less than foolhardy to erect smelters in face of the present uncertain assurance that their period of profitable operation would not be limited by the present abnormal market demands. To lease and rejuvenate the old abandoned works of the Middle West might be a possible solution, but even such an undertaking would be fraught with difficulties. The plethora of ore and lack of retort-capacity presents a knotty problem, the solution of which must necessarily be a difficult one under existing conditions.

It has been estimated that the annual consumption of zinc, as alloyed in brass for cartridges alone, by either side in the present European struggle is something over 50,000 tons. The local European smelters are in no way able to meet their demand. It is known that with the beginning of the present conflict, in August of last year, there were large stores of spelter in Europe, but these have been depleted and the output of the English zinc smelters, that at Budel in Holland, the Vieille Montagne plant at Viviez, and the Malfidano plant at Moyelle-Godault are unable to meet the present requirements of the Allies. The Germans are also making plans to regulate economically the supply of spelter to the needs of the armies and have organized the Zinkhüttenvereinigung for this purpose. The price of spelter in Germany has advanced materially, although zinc is supposed to be finding its way thither from the plants of Norway and Sweden, and the smelter at Angleur in Belgium is reported to be producing.

In normal times the consumption of primary spelter in the United States is about 340,000 tons, while the annual secondary consumption is about 50,000 tons. The estimated total spelter consumption of this country in 1914 was about 375,000 tons, and as such there was but a small margin to meet an increased export trade. While the American smelters have been forcing their output and some companies like the American Zinc & Chemical Co., the Hegeler Zinc Co., the Tulsa Spelter Co., the Granby Mining & Smelting Co., the Illinois Zinc Co., and the Matthiesson & Hegeler Co. will add materially to last year's production by reason of the increased retort-capacity, even this has not been sufficient to meet the demand for all purposes. The present smelter-capacity of the United States is possibly 600,000 tons of spelter annually. Of this output in normal times about 200,000 tons is consumed by the domestic galvanizing industry, and herein may be said to be the controlling factor in the present market. Substitutes for galvanized products have been finding a place in the American market for a number of years. Galvanized structural materials, pipe, wire, plates, and the like, are not as essential as formerly deemed by engineers and builders, and protective paints and coatings have proved in most instances to be satisfactory substitutes. With the advance in the price of spelter and galvanized products the protective paints and coatings have found an increased application. This has resulted in many of the former manufacturers of galvanized products abandoning the use of spelter. With the buyers for these companies out

of the market a great part of the 200,000 tons formerly required for galvanizing will be available for the European munition-contractors, with whom the price of spelter is of but secondary importance.

I do not believe that the present price of spelter is completely indicative of the supply and demand; not that the market is being manipulated, but that a complete readjustment of the trade in spelter is taking place, and until the new status of the industry is established to meet the requirements of the War, the balance will continue to fluctuate. For the present, the swing between supply and demand and the corresponding variations in price may be wide and a complete collapse of the market before it reaches its final balance is not without the range of possibility. Even after comparative stability is established, it cannot be considered of more than temporary importance, for with the cessation of the European demand, another readjustment must necessarily follow, and the position of spelter will again gravitate to conform with the ordinary channels of trade.

Chicago, June 24. E. H. Leslie.

Undercurrents

The Editor:

Sir—I wish to offer a somewhat belated criticism of a statement which I noted in re-reading the discussion of the subject of undercurrents in your columns. In your editorial comment on Mr. Ulrich's interesting letter in the issue of June 5, you make the statement that "the alluvial miner has been living in a fool's paradise, deluding himself into an idea that he was making a high extraction because nobody could prove that he was not saving all the precious metal."

As a member of the class designated in your somewhat inclusive term, I wish to state that the average alluvial miner is very far from living in such a beatific state of ignorance. He knows perfectly well that if he is making a 75% extraction he is doing well. The fact that he persists in being satisfied with this is in itself evidence that there is some reason for it.

The great bulk of gold won from hydraulic mining comes from small mines, for the most part, mines in which probably the total amount of capital invested is less than $100,000. The average gold-content is not very high—running from 10 to 20 cents per cubic yard—and in many cases the water season is not more than four months long. In this short time the water must be used to its utmost capacity to pay the fixed charges and interest, the expense of fitting up, and a small profit on the investment. The only way in which this can be done is to get the utmost capacity out of the sluices; and it is for this reason that the small operator looks askance at any complication of gold-saving devices that threatens to cut-down capacity.

When a man is handling a material whose total yield—if complete extraction were made—would only be about 12 cents per ton, his viewpoint is considerably different from that of the man who gains, by a complete extraction, as in the case of quartz mining, 40 to 50 times as much, and more. His only salvation is to get his 'overhead' distributed over as much yardage as possible. If he finds that he can increase his extraction 20%, but in order to do it he has to cut-down his capacity 25%, he is not inclined to make any changes. The conditions that prevail in the average hydraulic mine are practically prohibitive of maintaining a constant feed in the sluices, for instance; and alternate flooding and choking of any complicated gold-saving device will result in having to turn off the water until it can be cleaned out. This is ruinous, of course, to capacity. Conditions are not at all analogous to those of any other form of mining, even dredging.

This is perhaps one of the main reasons why hydraulic mining is today in the same primitive condition that it was forty years ago. It is better economy to let some gold go over the dump than to lose time and water. The bump of the bounding boulder through the sluices is about the only guide that the average operator trusts himself to follow.

Of course, where the black sand contains gems or semi-precious metals in sufficient quantity to justify their concentration and subsequent extraction, the case is, as Abe Potash would say, "something else again, yet." For this reason the articles by Mr. Nicol have a special interest; and as he seems to have avoided most of the reefs that have strewn the black-sand shores with so many wrecks, it is possible that our friend, the misguided alluvial miner, may be led to the adoption of some of the methods he advocates, provided, as he wisely says, that there is anything in the sand. The great majority of Californian hydraulic mines, however, in my opinion, belong to the class in which "only a mass of black sand with a little associated fine gold would be obtained."

To return to your statement regarding "the weird discrepancies between drill-hole results and shaft-sampling," I am of the opinion that there lies therein a profitable field for discussion, and I hope to be able as soon as I have time to contribute another article which will give the results of my own experience with this.

Chas. S. Haley.

South Fork, Trinity river, June 23.

Classification of Technical Literature

The Editor:

Sir—The Joint Committee on Classification of Technical Literature is extremely desirous of obtaining the assistance of your readers in making a collection of classifications of applied science which have been developed independently in the offices of manufacturing plants or engineering firms, especially those which exist in manuscript form, and have been used for filing or indexing data. The Committee would especially like to have copies of any extensions of present systems to cover any special industry or branch of engineering not now fully covered by the published classifications.

W. P. Cutter, Secretary.

29 West 39th St., New York, June 21.

Flotation at the Inspiration Mine, Arizona

By ANOTHER OCCASIONAL CONTRIBUTOR*

The Inspiration Consolidated Copper Co.'s mine near Miami, in Arizona, is estimated to contain 97,143,000 tons of 1.63% copper ore, mostly in the form of chalcocite. The ore at present being mined contains about 0.20% metal in the form of carbonate and silicate.

For some time past the company has been experimenting with a view to finding the best method of concentrating the sulphide ore before smelting. The first test-mill consisted of two sets of rolls, one Chilean mill, one Hardinge conical mill 6 ft. diam. by 12 in. cylinder, Richards hindered-settling classifier, Deister tables, some kind of vanner, and a 50-ton Minerals Separation flotation machine of standard type (Hoover's single-level apparatus). This mill was situated close to the Joe Bush shaft, on top of the orebody, and is now dismantled. It is understood that good results were obtained.

On a change of management taking place, a new test-mill was erected near the old leaching plant of the Black Warrior Copper Co., about 1½ miles from the new twin-shafts through which all ore will be hoisted when the large mill is running. This mill will be the largest, or rather will handle the largest tonnage, of any mill in the world, namely, 15,000 tons per day. It adjoins the test-mill as can be seen in the photograph published in the MINING AND SCIENTIFIC PRESS of May 29. The crushing and concentrating capacity of the test-mill is about 1000 tons per day, but it is limited by the capacity of the classifiers, elevators, etc.

The ore is at present hoisted through the Scorpion shaft and broken in a 'K' Gates crusher close to the shaft. From there it is conveyed to the 30,000-ton flat-bottomed steel and concrete bins attached to the crusher-station at the new shafts. It is then transported to the test-mill in Ingoldsby dump-cars (each having a capacity of 60 tons) drawn by steam-locomotives on a standard-gauge railway. A part of the new mill-bins (which are of steel and trough-shaped) is set aside for the use of the test-mill. On leaving these bins the ore falls upon a tray-conveyor, then to an inclined rubber-belt conveyor, where it is automatically weighed. At the head of this conveyor there is a magnetic pulley that removes pieces of iron and steel which may have got mixed with the ore. At this point there is a grizzly and a 36-in. Symons vertical-disc crusher. (This machine was described in the PRESS of May 22, page 820.)

From here an incline-conveyor carries the ore to the top of the test-mill, where it is divided into two streams, one going to a shaking screen from which the oversize falls into a 48-in. Symons horizontal-disc crusher, where it is crushed dry, and the other to a 5 ft. 6 in. by 8 ft. diam. Marcy ball-mill, where it is crushed wet without previous screening. The product of the Symons machine is fed to pebble-mills without any classification, being distributed in varying proportions by a mechanical device. This consists of a fixed horizontal circular vessel 103 inches in circumference, divided into four sections by vertical sheet-iron partitions that can be adjusted to give segments of any size, thus varying the feed to each mill as desired. By measuring the number of inches of circumference given to each division the proportion of feed going to each mill can be calculated. Above this receptacle there is a vertical crooked revolving iron pipe through which the feed comes from the Symons machine after being mixed with water. The revolution of the feed-pipe causes the pulp to be discharged into each division of the distributer in turn. In the bottom of each division is a hole through which the feed passes to launders leading to the pebble-mills.

The following kinds of pebble-mills are installed:

1. One 20 by 6-ft. Chalmers & Williams quick-discharge tube-mill with herring-bone gear engaging with pinion on a shaft directly driven through a flexible coupling by an electric motor.

2. One Hardinge conical mill, 10 ft. diam., with cylindrical part 28 in. long, driven through spur and pinion by two-belt transmission from motor.

3. One Hardinge conical mill, 8 ft. diam., with cylinder 72 in. long, with herring-bone gear engaging with pinion on shaft direct driven by motor.

4. One Hardinge conical mill, 8 ft. diam., with cylinder 36 in. long, driven in the same manner as No. 3.

5. One Hardinge conical mill, 8 ft. diam., with cylinder 44 in. long, driven in same way as No. 3 and 4.

Both silex and El Oro linings were tried in the cylindrical part, and pebbles set in cement in the conical part; and, in one mill, steel plates, which, however, did not last long.

Each pebble-mill has a drag-classifier attached, and the oversize in the product, except in the case of the tube-mill, is returned by a bucket-elevator to the mill from which it came. In the case of the tube-mill the oversize is returned to the mill by the drag-classifier, which is parallel with the mill. Both Danish and Californian pebbles have been tried.

The product of the Marcy ball-mill is classified in a Duplex Dorr classifier, and the oversize returned to the same mill. This mill has a capacity as a fine crusher of about 13 tons per hour. Of the final product only about 1% remains on 48 mesh. This mill is simply a strongly built cylinder supported on trunnions, contains about 10 tons of chrome steel or manganoid balls, and is revolved at 22 r.p.m. It was formerly fed through the trunnion,

*As this article deals with the subject of rival flotation processes, over which a thick veil of mystery is supposed to hang, the writer thinks it best to remain incognito.

then three scoops were attached, but now one large scoop is used. It is lined with manganese-steel plates and driven through spur and pinion by belting from a 200-hp. motor, using about 140 kilowatts. The discharge is at the opposite end to the feed-inlet and passes through grates composed of steel bars placed close together. The discharge area is more than half the entire end of the mill. It will thus be seen that it differs essentially from the Krupp ball-mill, in which the screens are placed around the periphery and the pulp has to pass through two screens before escaping. The pulp leaving the ball-mill contains about 40% of moisture. This is diluted before entering the Dorr classifier. The overflow from the classifier consists of 2½ to 3 parts of water to one of ore.

The power required to drive these different mills, their capacity, consumption of balls, pebbles, and liners are, of course, known only to the management, but it is significant that in the new mill all crushing will be done by Marcy mills.

Among other crushing machines that have been tried are the Bradley roller-mill, Symons roller-mill, Overstrom mill, and Allis-Chalmers hammer-mill. No rolls or Chilean mills, Krupp mills, or Marathon mills were tried in this plant.

The products of the Marcy mill, and such of the pebble-mills as are running, are united and elevated sufficiently high to flow to all the flotation plants without undergoing any preliminary table or vanner concentration. The feed is distributed to the flotation plants in the following way: It flows into the centre of a horizontal, circular, revolving apparatus of sheet-iron divided into five concentric circles or rings. Each circle has 20 holes in the bottom, and the proportion of feed to each flotation plant is regulated by opening the proper number of holes and allowing the pulp to enter a launder along which it flows to the flotation plant. Thus if the ring that receives the feed intended for one particular plant has 15 holes plugged and 5 open, this plant is, of course, receiving 25% of the total feed, and the actual tonnage passed through it can be calculated.

Automatic samplers, worked by a water balance, are used throughout the mill. All assays are done by the electrolytic method, using rotating anodes.

Most of the flotation 'oil' is added to the pulp at the head of the mill, being fed from a tank by a small bucket-elevator driven by a shaft having a cone-step pulley, so that the speed of the elevator and the quantity of 'oil' can be varied to suit the tonnage of ore being crushed. This is much more satisfactory than letting the 'oil' drip from a can. Any additional reagent that may be required is added at each flotation plant by dripping from a can.

The following methods of flotation have been tried:

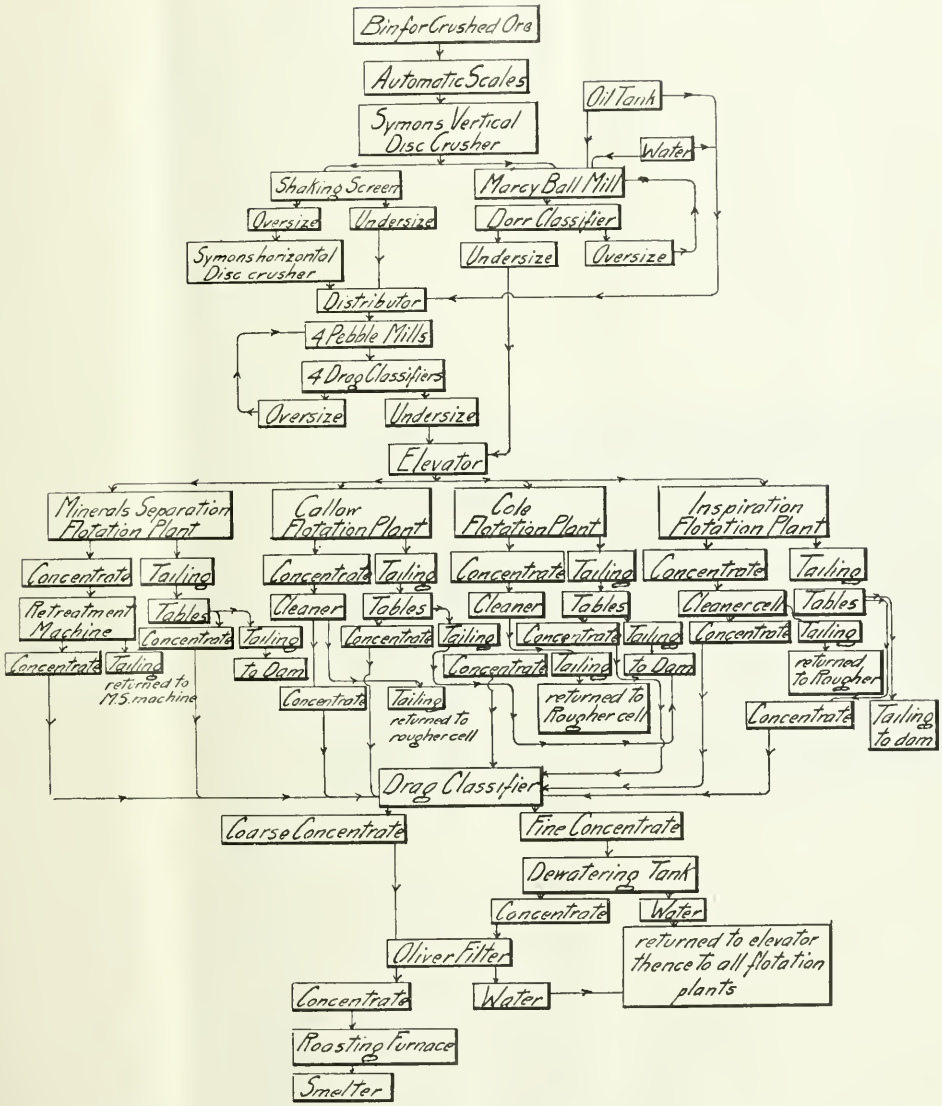
1. An 8-compartment Minerals Separation machine of standard type (as described in Hoover's book on flotation), having a nominal capacity of 600 tons per day. The agitation compartments are 3 ft. square, and the flotation compartments or spitzkasten, 5 by 3 ft. The spindles are driven through enclosed bevel-gearing by a pulley on a horizontal shaft. The overflow from the first six compartments was sent to the concentrate-bins without 'cleaning' or further treatment designed to raise the grade by eliminating insoluble matter and the overflow from the last two compartments was returned to the head of the machine. This machine was discarded.

2. A 12-compartment Minerals Separation machine of standard type, of the same capacity and driven in the same manner as No. 1, the additional compartments being intended to prolong the treatment. At first the concentrate and middling were dealt with as in No. 1 machine, but afterward the overflow from all compartments was 'cleaned' in (3), next described.

3. An 8-compartment 50-ton Minerals Separation machine of standard type, the spindles being driven by half-crossed belts from pulleys on a horizontal shaft. The overflow from all compartments was sent to concentrate-bins, and the tailing was returned to the head of No. 2 machine. This concentrate contained about 30% copper. These two machines were in use until recently.

4. An 8-compartment Minerals Separation machine of new type, known as a 'sub-aeration machine.' The agitation compartments were covered on top, and both mechanical agitation and compressed air were used. The agitation compartments contained cast-iron baffle-plates fixed to the sides, and the impellers were different from those used in the standard machine, but the spindles were driven in the usual way. The discharge from the agitation compartments to the flotation compartments was high up. The air used for the aeration of the pulp was introduced through a hole in the bottom of each agitation compartment at a pressure of about 2 lb. per square inch. It did not pass through any porous medium. This machine had the usual valves and suction-pipes in the bottom, but was afterward altered to (5) a machine of the Hebbard type, with agitation gear of the standard Minerals Separation pattern, but with horizontal discs in place of the usual screw-impellers. Each spindle makes about 300 r.p.m. In the Hebbard machine as used in Australia the agitators are driven from below. There are no spitzkasten, the overflow of concentrate-froth taking place from the agitation compartments. Consequently there are no suction-pipes and valves in the bottom, and no plugs to draw and replace when a stoppage takes place. The wooden partitions between the agitation compartments have been removed and cast-iron baffle-plates about 15 in. high substituted. Air is blown through eight holes in the bottom as in No. 4 machine (described above) and water under pressure is used to prevent pulp from entering the air-pipe. On a feed of about 300 tons per day this machine has given good results, and is still in use. The low-grade concentrate made by this machine is 'cleaned' in another machine of standard type.

6. A Towne-Flinn plant, or bubble-column concentrator with a nominal capacity of 50 tons per day. This consisted of (1) Pachuca agitator in which the pulp was mixed with oil, (2) a cast-iron vertical cylinder with a bottom of carborundum. The oiled pulp is fed into the



FLOW-SHEET OF THE INSPIRATION MILL. THE ROASTING FURNACE FOR CONCENTRATE IS AT THE SMELTER, NEARBY.

top of this cylinder through a pipe that delivers it below the surface. Air at a pressure of 5 lb. per square inch is blown through the carborundum. Bubbles are formed, that adhere to the oiled sulphide particles, forming a froth overflowing at the top of the cylinder into a launder, whence it flows to (3) a similar cylinder at a lower level, where it is 'cleaned.' The tailing from the first cylinder escapes through a hole in the middle of the carborundum and flows through a goose-neck hose (by which the water-level in the first cylinder is regulated) to (4) another cylinder where it receives similar treatment and more concentrate overflows. This concentrate also is re-treated in the same cylinder as the concentrate from the first cylinder, and the tailing from this cylinder or 'cleaner' is returned to the Pachuca agitator at the top of the building by a centrifugal pump. The air is furnished by a Roots blower. This plant was dismantled.

7. A Callow plant consisting of (1) Pachuca agitator 18 ft. deep by 4 ft. diam., (2) five cells, each 8½ ft. long by 2 ft. wide, with nominal capacity of 50 tons each per day, (3) one cleaner-cell 12 in. wide, (4) one air-compressor, (5) one receiver, (6) Connersville blower with a displacement of 3.3 cu. ft. of air per revolution, (7) two 3-in. centrifugal pumps, (8) 30-hp. motor.

Mr. Callow's letter in the PRESS of May 29 fully describes his process, so I need not go into further particulars, except to say that during the past few months the plant has been run without the Pachuca agitators; but this is by no means advisable. This plant has been running for about nine months and has given better results than any other that has been tried here. Forty of these cells are being installed in the new mill.

8. A machine invented by David Cole, of Morenci, Arizona, consisting of rectangular sheet-iron tanks with pipes laid horizontally in the bottom. The upper half of these pipes is composed of carborundum, and air from a blower is forced through them with the same effect as in the Callow, Towne-Flinn, and other pneumatic processes. Perforated wrought-iron pipes wrapped with flannel or canvas have also been used. The tailing from the first tank is re-treated, and the concentrate from all tanks is re-treated in a 'cleaner.' This plant is still running. A similar machine is in use at Morenci, and one is being built at Cananea, Sonora.

9. The company's metallurgist has devised an apparatus intended to combine the best points of the other machines but without infringing on any patents, except those of the Minerals Separation American Syndicate, from whom the company holds a license. It is called the Inspiration machine. At first it resembled a Callow apparatus with an almost flat bottom, the air being blown through canvas, but the froth overflowed at one side of the cell only, and there were partitions which, however, did not reach the bottom. It was twice as long as the ordinary Callow cell. The first concentrate was re-treated in a smaller machine of the same type, and the tailing from this machine was, as usual, returned to the 'rougher' cell. Recently other porous media for false bottoms have been tried. The machine is still in the experimental stage.

It will thus be seen that the company has spared neither time nor money in endeavoring to find the best flotation process. The test-mill has been working since January 1914, and about 50 flow-sheets have been tried. In the laboratory there are 6 small flotation machines of the Minerals Separation type in almost constant use.

The tailing from all the flotation plants is run over tables, those in use being Wilfley, Deister Machine Co.'s double-deck Simplex sand concentrator, Deister Machine Co.'s four-deck table, Deister slime-table, and Deister Concentrator Co.'s double-deck table. At one time the ore was concentrated on tables before going through the flotation process, but this was not found suitable for the Minerals Separation process, as it left too little mineral in the ore, and for this and other reasons it was discarded. The mineral saved on the tables is mostly pyrite. The 234 tables in the new mill are Deister Machine Co.'s double-deck type, the same as used in the Miami Copper Co.'s mill. No tests were made with any kind of vanner. The sand and slime were run over the same tables without classification, but this will be altered in the new mill.

The tailing from the tables flows to the dam, the retaining-wall being built by allowing the coarse sand to escape through cones or inverted pyramids attached to the tailing-launder.

The concentrate from all flotation plants and the tables, containing about 28% copper, 16% iron, and 26% insoluble matter, goes to a drag-classifier. From there the coarse concentrate goes direct to an Oliver filter and the fine to a V-shaped settling-tank, thence to the filter. The concentrate, after filtering, still contains a good deal of moisture. It is trammed to a bin adjoining a branch of the standard-gauge railway and loaded into bottom-discharge steel cars belonging to the International Smelting Co. Formerly it was sent to El Paso, Texas.

Water for the mill and domestic purposes is obtained by pumping from wells in the flat country about three miles distant. A large concrete reservoir has been built on a hill near the mill. Electric power is obtained from the power-house at the Roosevelt dam about 40 miles distant, belonging to the U. S. Reclamation Service, and the service is fairly satisfactory. The Inspiration company has an interest in the power-house at the International smelter near-by, where, in case of emergency, a supply of electricity can be generated by steam from waste heat from the reverberatories and from oil-fired Stirling boilers.

As mentioned in the annual report of the company (a summary of which appeared in the PRESS of May 1, 1915) 172,722 tons of ore was treated in this mill in 1914, so, although only a test-mill, it handles a fairly large tonnage. During the month of February last 90.3% of the copper occurring in the form of sulphides was recovered. The mill has been visited by mining men from all parts of the world.

C. E. Mills is general manager, Kenyon Burch is engineer, Rudolf Gahl is metallurgist, and G. E. Hunt is mill superintendent.

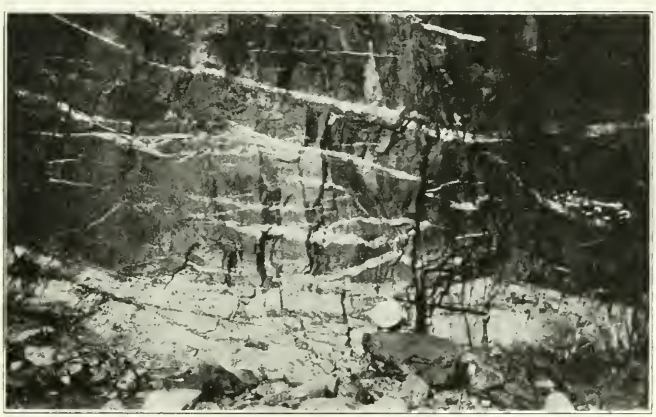
A copy of the flow-sheet at present in use is appended herewith.

Grass Valley Re-Visited—II

By T. A. RICKARD

The North Star vein has been followed to 6300 ft., which, on the dip of 23° north, is equivalent to a vertical depth of 2400 ft. Three of the four defined ore-shoots did not outcrop, but the discovery orebody was rich for about 700 ft. on the strike. The three ore-shoots that did not apex at the surface were found at 500, 1600, and 4000 ft., respectively. The North Star vein is remarkably continuous. Owing to a small repair in the Central, or vertical, shaft I was taken underground on the truck that runs down the old North Star shaft, which is an incline on the vein. This follows the vein for 6300 ft. and gives a good opportunity to remark its extraordinary continuity. It may pinch or widen, it may be a thin quartz seam or a mere parting, it may be a gouge-streak or six feet of solid quartz, but through all these vicissitudes the vein-fracture is continuous. The average of clean quartz is from 12 to 18 inches. The dip varies from a maximum of 45° to flat, but not in the shaft itself. Down to 4000 ft. the vein traverses diabase; below that it is enclosed within granodiorite. Here I may mention that the vein exploited in the Empire mine has been followed to 4800 ft. on the dip, or 2200 ft. vertical; in diabase down to 1300 ft., and granodiorite below. The North Star has several branches, some of them highly productive; for example, on the 3400-ft. level at the present time two of these, with diverse dip, are being explored and stoped. In places the fracturing in the diabase has produced a complex of veins requiring mining to be skillful in order that it may be economical. No marked cross-faulting is observable, but the lode-channel appears to follow an overthrust fault, causing overlaps and slips along which the healing mineral solutions have formed more than one duplication of quartz veins. Breccia and gouge are sufficiently plentiful to indicate that the vein follows a line of dislocation, as is further proved by the fact that the North Star displaces another vein fully 4 ft. in the western workings. On the 6300-ft. level, a large cross-vein (now the subject of controversy) has been cut and explored by a drift. It is most promising. The North Star vein has not yet been found or sought beyond this cross-vein, but it is proper to add that at 3000 ft. the North Star looked as if it had 'quit,' but it was found again, strong and profitable, for 3000 ft. more. At the bottom station a quartz-porphyry dike, 12 to 15 inches wide, is frozen to the granodiorite. This dike is cut-off by the North Star vein even where the latter looks feeble. Dikes of a similar character, but as much as 30 ft. wide, have been cut in the eastern workings of the mine. The miners call the quartz-porphyry 'marble' because it is smooth and hard-looking. Some good stopes went right through it; that is, the gold-bearing quartz was not interrupted by the dike, for the quartz-porphyry is pre-mineral although post-diabase.

Although large excavations have been made under the rather flat hanging wall of the vein, no extensive subsidences have ensued as yet, nor has the mine suffered from those sudden collapses of the overhang called 'air-blasts.' Something of the kind, however, must have happened in July 1912 when an area of about three acres fell, to the accompaniment of thunderous noise that lasted for about five minutes. No rush of air was noticed; indeed, the 'snuffs' left under the miners' dinner-buckets, heating the tea within, remained alight on the edge of the caved portion. The lights could be seen after the men had been extricated, but the buckets could not be recovered, the ground being too dangerous. A small hoisting-engine also had to be abandoned.



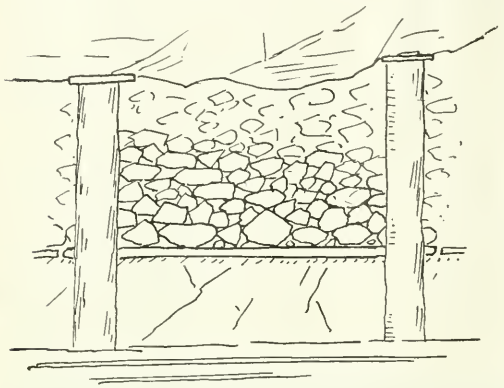
A TYPICAL STOPE-FACE IN THE NORTH STAR MINE.

The flatness of the stopes led to the invention, by the elder Mr. Foote, of a device for lowering ore along the foot-wall with the use of a gravity tram. This is the 'go-devil.' It consists of three sheaves on the same plane, one at each apex of an equilateral triangle, the wire rope passing round each in succession. The brake is applied by cramping a casting between the three sheaves, gripping all of them simultaneously.

In a mine so well managed, I saw one thing unworthy of imitation, and I may be permitted to make a note of it, as it was to be seen only in old workings. Nothing of the kind was to be observed in the newer workings. I refer to the use of a pole, behind two posts, as a base for

stope-filling, the face of the fill being upright instead of being founded on the foot-wall itself with a batter backward. The fill, being laid on a perishable timber, is bound to collapse when the timber rots.

Ordinary sampling is considered impracticable in a vein containing so large a part of its valuable content in



WRONG WAY TO FILL STOPES.

the form of free gold. The development faces are sampled only if no gold is visible. Samples are not taken even if the showing of gold is intermittent from day to day, particularly if the quartz contains "good-looking mineral," that is, lead and pyrite. The better grade of ore shows gold together with a heavy sprinkling of sulphides. If the quartz is white, without sulphides or visible gold, it is assumed to be poor—that is, waste. Quartz that is "white as a hound's tooth" is almost certain to be barren. The stope-faces likewise are judged by the eye; no samples are taken unless the ground appears to be so poor as to suggest discontinuance of stoping in any particular working. Instead of regular sampling it becomes necessary to establish a thorough system of supervision. Stope-bosses are employed to watch particular faces, not only to prevent the breaking of excessive waste, but to minimize the stealing of coarse gold. Usually three of these are on the pay-roll, besides three more 'specimen bosses,' one on each shift, whose duty it is to go through the workings and remove all patches of coarse gold, using a moil or hand-pick. They fill from 12 to 20 small sacks, weighing from 50 to 75 lb. each, per month. This stuff is worth from $500 to $2000 per month. Despite such precautions, there is a good deal of 'high-grading,' or theft. In addition to the six junior bosses mentioned, two special stope-bosses are supervising the 3400-ft. west workings, where a large crew is employed just now, so that 8 shift-bosses of this kind are on the pay-roll. The whole system of underground supervision, including the ordinary foreman and shift-bosess, entails a cost of 18 cents per ton, on ore yielding $9.50 per ton.

To break the gold-bearing quartz as clean as possible is the ideal, but it has to be adapted to economic conditions. At one time an effort was made to 'resue,' that is, to strip the vein on its hanging-wall side, but it proved unsatisfactory. The vein shows an increasing proportion of stringers as the mine is deepened and it is a fact that more of these stringers are now included in the ground stoped. Nevertheless the profit per ton has been nearly constant throughout the life of the mine, as the data in the table below indicate.

In preparation for stoping in the deeper portion of the mine, a new plant, to cost $78,000, is being erected at the Central shaft. This includes a steel head-frame, a hoisting engine, and a sorting annex. The hoist will be a Nordberg simple duplex engine of 28 in. diameter and 48-in. stroke. It will raise 4 tons at a rate of 1200 ft. per minute from 7300 ft. on the dip of the vein, that is, 2750 ft. vertical. The two drums will be 9 ft. diam.

NORTH STAR VEIN

with a 6-ft. face grooved. The engine will be provided with a Foster super-heater, to heat the air up to 370°F. The rope will be 1½ inch, made of plow-steel. The head-frame, 100 ft. high, is of structural steel, supplied by the Minneapolis Steel & Machinery Co. The weight is 96,000 lb. Ore from the mine will be discharged upon grizzlies, sorting out the fine, the remainder falling into steel bins, from which it will be fed to an oscillating picking-table. Between the feeder and this table the ore will be sprinkled to facilitate sorting.

In the repair-shop I was shown the device invented by the machinist, W. D. Paynter, for testing the drills used in the mine. It is a machine whereby the blow of a drill against a plunger is transmitted through oil to a diaphragm, the distension of which is amplified by a lever, at one end of which is a pencil that registers the force of the blow on paper laid around a revolving drum. For instance, a Waugh No. 50 drill on arrival from the factory was tested. Under an air-pressure of 95 lb., it struck 1932 blows, worth 25 foot-pounds, per minute. This was on December 9, 1914. After being used for 45 shifts the drill became ineffective underground and was brought to surface for testing by the Paynter machine.

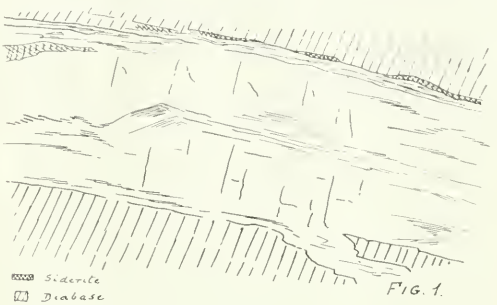
DIAGRAM OF DRILL-TEST.

Under the same air-pressure it now struck 2040 blows per minute, but only 15 ft-lb. per minute. This was on May 8, 1915. After being repaired, and a new 'barrel,' or cylinder, supplied, it struck 2220 blows worth 27 ft-lb. per minute. This also was on May 8. Whereupon it was returned underground in a state of first-class efficiency.

Another instance may be quoted. A year ago a new Ingersoll-Leyner No. 18 had been received at the Empire mine, where the men underground claimed that they could not get good service from it; it was condemned after it had been tried against an older drill. The discredited drill went to and fro from the mine to the repair-shop until finally it was sent for a test to Paynter, who endorsed its inefficiency. Whereupon a new drill, with a demonstrator, was sent by the manufacturer. This gave a good record on the testing-machine. By changing parts successively, it was ascertained that the valve-chest of the culprit was defective. When the valve-chest of the new machine was put on the old one, the results were as good as on the new one. The two cards are given above.* Thereupon the manager of the Empire bought one of the Paynter machines.

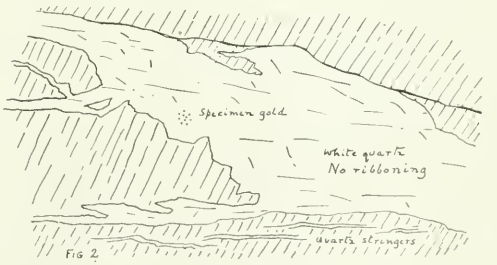
Of course, the use of such a testing-machine prevents unfit drills from being sent into the mine; it serves to discover weak spots, to cause prompt repairs and replacement of worn parts. The cost of operating drills, that is, the labor of the driller, air for power, maintenance of air-lines and of the drills themselves, steel consumption, sharpening, and distribution, altogether amounts to $100,000 per annum or one-third the total mining expense, which means the cost of breaking the ore and delivering it into the mill-bins.

At the North Star the Water-Leyner No. 8 (with 1½-inch hollow steel) and the Waugh 12-A (with 1¼-inch



A TYPICAL SECTION.

cross-steel) are in general use. The latter is being discarded for the Ingersoll No. 26, a hammer-machine of the column-mounted type equipped with a butterfly valve and using hollow (⅞-in. hexagonal) steel. It is found that the speed of drilling is more nearly proportional to the number of blows than to the force of the blow. With the big steel and a 2¼-in. bit the most effective blow is one of 45 ft-lb.; beyond that point the effectiveness of the drill is not progressive. The Water-Leyner with a 2¼-in. bit will drill 0.2 ft. per minute



A RICH SPOT IN THE VEIN.

under 1300 blows of 45 ft-lb. each per minute, while the Ingersoll No. 26 will drill 0.25 ft. with a 1¼-in. bit, 2200 blows, and 18 ft-lb. per minute.

The old Cornish pump must not be overlooked. It has been running steadily since 1884. The rod is 2400 ft. long, made of wood spliced together at 20-ft. intervals with iron straps. The column starts with a diameter of 16 inches and is reduced successively to 6 inches at the bottom. The 'bob' was made for the Potosi mine on the Comstock, and was then used at the Scotia, before it

*See also MINING AND SCIENTIFIC PRESS, August 2, 1913, and 'Tests of Rock Drills at North Star Mine, California,' by Robert H. Bedford and William Hague, Trans. A. I. M. E., 1914.

came to the North Star. The pump-rod weighs 155,000 lb. and is balanced, of course, by the bob.

Of late there have been rumors, well founded, of a conflict of apex-rights over the vein cut on the bottom level of the North Star. This vein dips from the opposite side, that is, from the direction of the Empire mine. Hence the possibility of litigation. It would not be proper for me to express any opinion on the matter, even if I were well informed concerning all the facts, which is far from being the case, but I do appreciate that the poor 'apex law' is again in danger of being stultified, for in the Grass Valley district the veins are so numerous, and interlocking, and their apices on surface so often non-existent, that the adjudication of mining-rights is beyond the judgment of man. Having regard to the sagacity of the owners of both properties and the ability of their advisors, both legal and geological, I have every hope and expectation that litigation will be avoided.† It is true that a minor newspaper stated that the North Star had offered to buy the Empire for $5,000,000, but that the offer had been countered with a demand for $7,000,000. This little story may be disregarded. Each mine has ground enough, and equipment sufficient, to constitute a first-class economic unit.

Leaving this delicate topic, let me close my notes by a reference to the amenities of the place to the pine woods, the pleasant houses that they shelter, and the earnest technical men, and their accomplished wives, who find a home there. At Grass Valley life has lost the uncouthness of a frontier settlement. The second growth of pine has clothed the bareness of the hills, from which the pioneers stripped the tall timber. Now an adult forest has risen among the old stumps. The ground is carpeted with the brown needles. A clearing gives a glimpse of the snowy peaks of the Sierra Buttes silhouetted against the blue. Sunshine in golden lanes falls athwart the forest spaces. Quiet reigns. Only the muffled roar of the stamp-mill comes as a reminder of the resourceful energies that are ever at work in the depths underground.

The Missouri is the muddiest river in the Mississippi Valley; it carries more silt than any other large river in the United States except possibly the Rio Grande and the Colorado. For every square mile of country drained it carries downstream 381 tons of dissolved and suspended matter each year. In other words, the river gathers annually from the country that it drains more than 123,000,000 tons of silt and soluble matter, some of which it distributes over the flood plain below to form productive agricultural lands, but most of which finds its way at last to the Gulf of Mexico. It is by means of data of this kind that geologists compute the rate at which the lands are being eroded away.

Talc and soapstone production in the United States in 1914 was 151,088 and 21,208 tons respectively, valued at a total of $1,865,087.

†This anticipation has proved, I regret to say, optimistic. Legal proceedings are now pending.

Terne Plates

This item of manufacture has come into prominence as a substitute for galvanized iron in roofing and outdoor protection. The terne plate is a sheet of iron coated with a mixture of lead and tin, the proportion of these two metals varying from 15% tin to 25%. The tin is said to cause the lead to adhere to the black sheet of steel. Owing to its greater cost, the manufacturer uses as little tin as possible. In regard to the merit of terne plates as compared with other coated sheets, it would appear that it depends upon the weight of the coating. As commonly quoted, this coating ranges from 8 to 40 lb. per box of 112 sheets, each of 20 by 28 inches. Thus the 8 lb. of alloy is spread over about 800 square feet. It follows that a mere scratch will expose the steel to corrosion. It is a curious fact, moreover, that 0.15 to 0.25% copper in the steel will increase the resistance to corrosion. The two metals form an alloy. Those in the trade say that a 30 or 40 lb. coating should be used if terne plates are to equal galvanized sheets in efficiency. The best proof of the superiority of galvanized sheets is the growth in the use of them. Painted black sheets were widely used at one time, but they have not the vogue of a few years ago. On the whole, consumers are loath to use any substitute for galvanized iron and will pay the higher prices, provided they are not prohibitive. Probably the prejudice against the old-fashioned 'tin roof' is due largely to the variable composition and quality of the coating used. In order to overcome this prejudice some organized effort toward standardization is necessary.

Gold-Mining in Ssu-Chuan

Gold is found in many places in the province of Ssu-chuan, China, and the upper reaches of the Yangtze are known by the natives as the Kin-ho, or gold river. Alluvial gold workings may be seen along many streams; near Ta-chien-lu, for example, 500 or more men are at work. The most important lode mine so far found is at Maha, in the southwestern part of the province, about 50 miles northwest of Ning-yuan-fu. Work on the mine was started some years ago, but on account of revolutionary disturbances not much has yet been accomplished, although several large and productive veins have been found. Two Chinese engineers who have studied in Belgium are now in charge of the property, and some 1200 men are employed. Funds for financing the work of development have been provided by the Government and it is the intention to purchase the necessary equipment in America.

Drilling efficiency depends upon the following factors: (1) knowledge of the rock; (2) the selection of a machine-drill that is suitable for the work in hand; whose dead time in handling and mounting is low, and that is capable of keeping pace with the drill bit, and (3) a study of the suitability of drill-bit.

Mining in Utah

By L. O. HOWARD

The recent flurry in the lead market has stimulated local inquiry as to the possibility of increasing the state's production of this metal. Aside from the excellent position of copper, a rise in the price of lead and silver evokes the greatest interest, inasmuch as the production of these metals comes from a wider area, and as Utah is surpassed by but two states in the production of lead and its ores, and by but one in lead-silver ores.

As is well known, the major part of the lead-silver production is made by the mines of Bingham, Park City, Tintic, and Beaver county, the first two contributing sulphides and the latter two shipping most of the carbonate tonnage of the state. Much of the ore from Park City and Bingham is in the form of a concentrate, that from the former, particularly, carrying considerable zinc, most of which is lost in smelting, except in those ores or concentrates that are amenable to electrostatic separation, and which are so treated at one of the Salt Lake valley plants.

As to the possibility of increasing the mine production, it is to be expected that Bingham and Park City can largely increase their shipments, although the uncertainties of the market have operated to prevent a too hasty expansion of the scale of operations. In the near future we may look for a greater output of the finer concentrates from both districts, a large producer in each being on the point of installing a flotation process.

In the Tintic camp there has been some increase in the number of men employed and in the number of leases taken up, both underground and on old dumps.

With lead under four cents, producers of sulphide ore have of necessity depended on the silver content of their ores for any appreciable profit and it can be easily understood that a price for lead that would enable consistent profits to be won from that metal would be most welcome. Producers rather prefer a price of five to six cents, justly believing that a higher price is likely to lead to later demoralization of the market, through discouraging the use of lead where it is not essential.

In considering the position of the smelters it is evident that too high a price will operate to limit ore-purchases to those made under contract or otherwise most desirable, since it would not be sound business to accumulate any stock of ore in excess of smelting requirements, in the face of a possible quick decline in the market. So that the final limit to an increase in production will naturally depend on smelting capacities.

It is always difficult to give accurately the capacity of lead-smelting works in terms either of lead ore or lead bullion, on account of the variable nature of the materials charged, for a considerable portion of the charge may consist of ores valuable for their gold and silver content, with lead at a minimum; and it may not be and is not likely to be practical to treat only ores high in lead, in order to take advantage of temporary high prices. But using as a basis of approximation the average charge smelted and omitting consideration of any increases brought about by better metallurgical practice, or other favorable factors, an approximate estimate is possible, which will serve to point out at least the direction in which the limitation lies.

Fourteen out of a total of 19 lead stacks are now in operation, treating approximately 3500 tons of charge daily, out of a possible furnace-capacity of about 4750 tons, or at about 75% of capacity.

Inasmuch as fully two-thirds of the ore is roasted, it is evident that unless there was a large increase in receipts of oxidized ores, the roasting equipment might determine the limit of capacity. This equipment could not be increased generally without increasing flue-systems, bag-houses, etc., and would not be considered while the market was unsettled. As near as can be estimated there are in operation the equivalent of 12 Dwight-Lloyd sintering machines, out of an installation of 16, sintering about 1800 tons of charge daily, out of a possible capacity under present operating conditions of about 3000 tons. There is also further sintering capacity in the shape of Huntington & Heberlein pots, capable of treating an additional 400 tons of charge daily. Without making any arbitrary assumptions as to the amount of lead ore on the charge, the above figures give the relative proportions of present and possible capacity, which is all I wish to emphasize in this review of conditions.

Should furnace and roasting capacity be in harmony, the one or the other might be mentioned as marking the limit, but it happens that at one plant with furnaces idle, roasting equipment is all in operation while at another all blast-furnaces are operating while part of the roasting plant is not operated. This, then, limits the possible increase in the charge to a few hundred tons per day, and as higher prices call out lower-grade ores, it is questionable whether the lead on the charge would be greatly increased.

A factor of no little moment in connection with the treatment of greater tonnages of sulphide ores is the limit placed on such increase by the Courts as a result of certain smoke suits against some of the smelters.

Taken in all its aspects the threatened high price for lead has again emphasized the desirability of the producer selling his ore under contract. One clause favorable to the smelters, which is generally lacking in lead contracts in this market, but is in frequent use in zinc contracts, is a provision that enables the smelter to share in increased profits from higher prices, through automatic increases in charges with increased prices. As it

is, the same smelting charge is made, whatever the price of lead. A tendency to get some of this increased profit is manifest in the reported payment of only one-half the advance over 4½ cents, on ore bought in the open market recently. This, of course, does not affect present contracts. While smelters may anticipate enhanced profits from ore now in stock bought at low prices, there is little to be hoped for in the way of extravagant profits on ore bought at high prices, as the decline following a rising market is usually rather sudden, while the effect of increasing prices is but slowly cumulative, as it relates to the favorable side of the smelter's balance-sheet, and it is not an attractive proposition to carry metal bought at high prices for the sixty or ninety days that may be necessary to beneficiate it and market it.

One source of helpless grief to local smelters is the high content of some of the ores in zinc. That this grief is not illusory is evident in the present high price for a product that these plants must waste. To throw away a metal worth in the neighborhood of 25 cents to save another worth 5 or 6 cents surely gives rise to a feeling that elicits our sympathy.

It did not require, however, the stimulus of high prices to create a widespread spirit of research into methods that might save this zinc, in which effort Utah is not at all backward. A discussion of this phase of the subject must be postponed for the present.

There is not much activity looking to the improvement of milling conditions. Operators are not slow to see the possible advantages in flotation processes, and, in spite of hampering litigation, substantial progress is being made. When the new Callow plant is installed at Park City, two of its four milling plants will be equipped with flotation apparatus, and the Utah-Apex at Bingham will mark the third installation of flotation in silver-lead-zinc mills, of which there are but five of any importance in Utah. Of importance also in the treatment of the silver-lead-zinc ores is the proposed large increase in the capacity of both the wet and dry (electrostatic) mills of the United States smelting company at Midvale, which may go into commission in the next sixty days.

The favorable price for copper has brought about the complete recovery of this business from the early depression of wartime, and has also aided to repair certain disastrous conditions that existed previously to that depression. There is not the same relative opportunity for betterment to the small producer of copper ores that exists for the lead producer, since, although there are some small producers of copper and several large producers of lead, the larger part of the copper production comes from big-scale operations, while many smaller producers and lessees aid in swelling the lead output.

The copper price, however, lends effective aid to the exploitation of the low-grade ores of the Ohio Copper Co., which is to be undertaken by Salt Lake, Butte, and New York interests. The profit accruing to this company from unsold copper, tied up some months ago when prices were low, has added a large amount to the assets of the company and it is hoped that the favorable combination of circumstances will place the mine upon its feet once more.

Nor has activity in the search for precious metals been lacking. Discoveries of rich specimens of gold ore in the Bull Valley district near Modena has lead to an increased output of interested boosting in the daily press, but in lieu of authentic and definite statements of footage and grade of ore, and demonstrated continuity of ore with depth, conservative men are withholding judgment. A fair sized boom is on.* Exceptional specimens have been found in fractures in the limestone. The high-grade ore is itself mineralogically remarkable, occurring in a well crystallized calcite. The lower-grade is found in or near porphyritic intrusions, so highly altered as to obscure their nature. The locality appears promising in so far as the milling of $5 to $20 ore is concerned. There has been too little development, however, to permit a confident judgment as to its importance. Only recently a piece of rock containing a large amount of free gold was reported to have been found near Quail Springs, some three or four miles from the pioneer prospect of the district, the Hamburg, where the first work was done about eight years ago. The mineralized area may have an extent of six to seven miles by three or four miles. One company is reported to be driving a cross-cut adit which will cut its vein at a depth of 800 ft. below the outcrop.

At Park City some progress is being made in treating the low-grade silver-lead ores of the American Flag by the chlorination process used at the Park City Mills plant. A capacity of 30 tons per day has been reached with the new Holt-Dern roasting furnace, and it is expected that this can be doubled. At this capacity expenses are being cleared. The ore carries 18 oz. silver and $2 in gold, a little copper, and some lead, but not enough to be recognized by the smelters in settlement-sheets. Silver extraction is satisfactory and lead and copper are saved, but the gold extraction has not yet come up to expectations, and a lot of pioneer work has been necessary, since the original plant applying this process on the Ontario stope-fillings did not have to extract the gold. This latter mill is being dismantled and will be re-erected in place of the Knight-Christensen mill in the Tintic district which was destroyed by fire before reaching wholly satisfactory operating conditions. With the opportunity to erect a plant to suit the process, rather than being under the necessity of adapting an old plant, interesting results are expected. The plant as finally operated at Park City earned a profit, but the new arrangement promises a better ore-supply.

One of the first steps looking to the utilization of the potash (alunite) deposits of Marysvale is the awarding by the Minerals Products Co. (said to be affiliated with the Armour interests) of a contract for a portion of its aerial tram from the deposits to the railroad. So the addition of another to Utah's already diverse mineral industries seems to be well under way.

*References to this discovery appeared in our issues of June 5 and June 12.—Editor.

Speculation in Mines

By F. LYNWOOD GARRISON

This is a topic that may be viewed in many different ways. Speculation or gambling is a primitive instinct, and in its crudest forms is a common practice among savages. Civilized man may check and cloak his primitive impulses, but the world of today is painfully aware, as perhaps never before in modern times, how little progress the white race has actually made in this respect.

The word 'speculation' is thus defined in the Century dictionary: "To invest money for profit upon uncertainty; take the risk of loss in view of possible gain." And 'gambling' is stated to mean: "To play any game of hazard for a stake; risk money or anything of value on the issue of a game of chance, by either playing or betting on the play of others; hence to engage in financial transactions or speculation dependent for success chiefly upon chance or unknown contingencies." It is evident that there is no great difference between the one meaning of the two words.

Mining, especially metal mining, is usually regarded as speculation. It is certainly not often a proper sphere in which to invest the widow's mite or the orphan's portion, but it is surely an attractive and proper field for the vigorous man with plenty of red blood in his body.

Now in one conception a mine never produces anything: it creates nothing in the sense of a farm yielding crops. It is the storehouse, if you please, containing an undefined and unknown amount of treasure, or what may be such if it does not cost more to take out than the product is worth in the market. In other words, a mine is what actuaries term a liquidating or wasting asset. Every pound of ore taken from a mine makes it just that much less valuable. Actually the taking of ore from a mine might make it more valuable because the act of doing this may develop the property and show resources theretofore unsuspected. Indeed it is seldom possible to be sure when a mine is completely exhausted, and what is waste-rock today may be ore tomorrow by reason of changed conditions. We certainly cannot expect the investor to view and understand such matters in the same way as an experienced mining engineer; the trouble is, the investor often thinks he knows as much, or even more, than the engineer.

When the Tonopah mine was discovered in the early part of 1901, Nevada as a mining region was as dead as Herod. Probably if the exploration companies that are today advertising for mining properties, but never appear to purchase any, had been then in existence, they would have appended to their advertisement "nothing wanted in Nevada." I well remember when the Tonopah mine was first brought to Philadelphia. The chief backer of it offered me some stock at a very low price, and when I asked him who was their engineer, he replied that they had, and needed, none. For that reason the proposition did not appeal to me; I failed to purchase the stock, and missed getting a good thing. My position in the matter was wholly logical and sound; most companies that undertake to mine without an engineer come to grief, but in this instance an engineer was really not absolutely necessary, for the mine at that time was too rich to be spoiled by any amount of bad management. It was in fact, a rank gamble, but successful; and it subsequently had a host of neighboring imitations, most of which ended in disaster.

The effect upon the public mind of such fortuitous ventures is on the whole distinctly bad: a crop of irresponsible promoters springs up and almost any old hole in the ground may be financed if presented with sufficiently alluring statements and literature. The eternally young-old game of getting something for nothing has an irresistible effect upon the human mind at such periods. It is a species of insanity, and we have had many instances of it in the history of the country since the days of the California gold rush in 1849. The psychology of public opinion is often inscrutable, but on the whole when allowed free and unhampered expression is generally right, if not perverted by greed, suspicion, and misinformation—a trio of faults one might suppose modern civilization had done much to dispel. It is perhaps needless to expatiate further upon human frailties; we all have our share of them.

The important thing in mining ventures is to discount the inherent risk and in doing this the public should be brought to recognize that mining, especially metal mining, is a highly technical business, and that to place such a business in untrained hands is to court disaster. The fact that there are not a few instances in the history of the country where men perfectly ignorant of minerals, rocks, and mining have discovered valuable ore deposits and become rich thereby, is no argument to the contrary. Mere chance or fortuitous circumstance is no proof of knowledge or skill. These remarks are so self-evident and trite, one almost hesitates to make them, but they contain homely truths that cannot be too often reiterated.

The cardinal principle in mining is to consider that such a venture or investment is never perfectly safe until the original amount involved has been equalled by the total dividends received. Moreover, it should be clearly understood that until this stage is reached the dividends do not represent profit but a proportionate return of the principal invested. A disregard of this precept is a common error, especially with women. It cannot be too often repeated that a mine is a wasting asset that necessarily becomes less and less valuable as it is worked. It is, of course, ordinarily impossible for an investor to know when the mine is likely to be exhausted. The engineers in charge may be able to approximate closely the period when this may be expected, and through them, of course, the information should reach the directors, but

the directors do not always share their knowledge with the stockholders. A surprising thing about the mining business is the tenacity of life of some old properties. Sometimes they are supposed to be completely worked out, when new orebodies are found; or, in other instances, ore previously too lean to be worked may later become a valuable asset by virtue of improved mining and milling methods. Then again, old tailing-dumps may be reworked to yield a substantial profit or the mining company may have accumulated a substantial surplus that can be invested in a new mine, thus maintaining the value of the stock. These observations tend to show that the mining investor is nearly always at the mercy of the managers of the property unless he be himself a skilled miner and has opportunities of examining the property.

In theory at least a mining company should not issue mortgage-bonds on its mines, or at any rate their term should be so short as to be well within the probable life of the mine.

The most important factor in financing a mining enterprise is one rarely given sufficient weight, that is, establishing ore reserves. It goes against human nature to see thousands of dollars put into the ground when not one cent is coming out; the average investor can seldom appreciate the logic and soundness of such a course of procedure. Herein, thus expressed in simple terms, lies the essential difference between absolute speculation and investment; obviously money spent on a mine when there is no definite and certain knowledge as to what amount of ore may be taken out, is speculation; whereas, suppose we have a million dollars worth of ore blocked out in a mine and we know for a fact that it can be taken out, milled, and turned into money for a cost of say $600,000, yielding a net profit of $400,000. It is evident that any amount put into the mine not to exceed $400,000 is an investment, and as a speculation it is logical to suppose that this same mine which produced a million dollars of ore will very likely yield considerably more.

I am convinced that we can never hope to persuade the general public to accept this view of mining. Men in general regard metal mining as a gamble and business people who are absolutely sane in their everyday affairs are ready in 'good times,' when money is plentiful, to listen to the tales of the irresponsible promoter, the fake 'mining expert' and the irresistible lure of getting rich quickly. When times are 'hard,' as at present, the promoter of this class with his bedfellow 'the expert' are hibernating somewhere, patiently waiting for better days to come when the tradesman will have a little spare cash to throw his way. Anyone who has not had actual experience with such matters could hardly believe the credulity and crass stupidity of many seasoned business men when carried away by the delusive blandishments of these fantastic schemers.

Far be it for us to discredit and discourage the honest and decent man who seeks capital to promote a meritorious and attractive mining proposition. He has a hard row to hoe at the best of times because he hesitates to distort the truth or minimize the risk, and if he fails to sing a sufficiently alluring song the money will be shy, but once let him pipe the right tune, the dollars become nimble and flock like sheep to be led where and when he pleases. If the promoter can once convince a man he may get something for nothing, there seems to be no limit to the folly of which human beings may be guilty.

No business depends more upon accuracy of judgment and sound technical knowledge than that of mining in all its branches. The mining engineer must not only be well versed in the intricacies of his profession, but amply endowed with imagination, that he may be equally able to determine what is based upon fact and what is mere fancy, and, what is more important, the limits to which it is safe to let imagination carry him.

Honesty and frankness are absolutely essential in the engineer; the would-be investor must be neither discouraged by pessimism, nor allow optimism to lead him astray; yet, if the picture be painted in too dark colors we may be sure the capitalist will button up his pocket and no risk be taken. The subject, therefore, resolves itself down to a dependence upon the engineer's sound judgment and technical accuracy. With large investments in unproved properties one engineer should be used to check another, no one man's judgment may be wholly trusted, and a careful engineer will himself seldom desire or permit such a thing to happen. But the capitalist should do his part also with the facts before him and his knowledge of the character of the men who have gathered them. The final decision must rest with him, he must weigh and consider most carefully the speculative elements free from cupidity, because in nine cases out of ten it is the lure of avarice that gets the better of his judgment.

It is pertinent in this connection to observe that the whole structure we call modern civilization rests upon the use of metals and they cannot be obtained except by mining. That the earth will continue to yield them indefinitely at the present rate no mining engineer of wide and mature experience will venture to assert. Rich deposits are becoming more and more rare. In the days of the Roman empire the streams and gravel-beds of Central Europe yielded considerable gold and at the same period the alluvial deposits of Cornwall produced the tin that made Tyre famous. The first historical fact has long since been forgotten, the lode mines of Cornwall many years ago eclipsed the stannaries of the ancients and now in turn these lodes have about been exhausted.

I cite these cases to show what we may expect in this country, large as it is, ever bearing in mind that the rate of production and consequent exhaustion is now vastly quicker than in Roman times. It is true the modern mechanical and chemical methods of ore treatment enable us profitably to mine low-grade ores that twenty, or even ten, years ago were of no value whatever. But it is doubtful if the limits in this respect are not now nearly in sight, unless the market-price of most metals materially increases.

The world's production of gold between 1912 and 1913 decreased $17,000,000, and in the year following $7,500,000.

Soetbeer computes the total production of gold in the

world since the year 1493 at $14,775,110,000, an amount about only one-third the estimated cost of the War in Europe if it lasts a year from August, 1914.*

The consumption of the gold in the arts is steadily increasing, and the demand for its use in commerce as a standard of value knows no limit. The logical conclusion from this review of general facts is that the price of metals must steadily advance; of course, there will be fluctuations, but the average level must tend to become higher as an inevitable result of the ever-increasing demand and the exhaustion of rich deposits with few new discoveries to take their place. The general tendency will be—indeed, it is already evident—for mining of all descriptions to segregate into the hands of large companies on the principle of large production upon small margins of profit but with an aggregate sufficient to yield a steady but relatively moderate return upon great investments of capital. The operations of such large companies are usually so diversified and distributed over a number of properties that the failure of one does not necessarily seriously affect the general business of the operating company as a whole. Hence the purchase of shares at reasonable prices in such organizations tends to become more of an investment than speculation. There is no doubt the segregation of mining operations into the hands of large corporations is a distinct advantage to the conservation of national resources. A large company, as a rule, is less wasteful than a small operator. It can afford to set aside its low-grade ores until such times as they may be worked at a profit, whereas the individual operator or small company can seldom do it, as he must look for immediate profit and pick out the rich spots, abandoning the rest as worthless, and often leave the mine in such condition that it cannot be re-opened.

As a check upon individuality, these tendencies are unfortunate. No country in the world has ever offered such opportunities for the development of the individual as has the United States and Canada. The time was, and not long ago, when the individual might discover an orebody, develop it into a mine, and become rich thereby. Such a possibility was obviously predicated upon the ore being rich and the operator having some small amount of capital; but we all know these opportunities are becoming more and more rare and are largely responsible for the cry "what is the matter with prospecting?"

The theme suggests other reflections, but I have said enough to show my own views concerning the speculative side of mining. The problems now presented to the young mining engineer are materially different from those we had to meet in our younger days 25 years ago. The fundamental principles of life do not conspicuously change, but the adjustment of the individual to shifting conditions demands constant attention, and the man who fails to adapt himself and blend gracefully with the current of events is not likely to achieve much or make himself a useful member of society.

Before concluding these few remarks some reference is appropriate to a few facts of timely and fundamental importance. The metal-producing industry of the world is chiefly in Anglo-Celtic hands. Germany, the greatest manufacturing nation of modern times, extracts from her own territory but a very small amount of the metals and has to depend upon importation to meet the rapidly increasing demand of metals for her industries.

Germany's metal requirements are met in two general ways: by importation of raw ores for treatment in her metallurgical establishments and by the purchase in outside markets of the crude metal itself. It seems curious that such a strong virile people as the Germans should evince so little interest in mining enterprises outside their own country, especially in view of the fact that an abundant supply of the metals is absolutely necessary to their continued prosperity. The only way I can account for this fact is that the Teuton is not a good sport, the mining game does not appeal to him as does trade and manufacturing, in which he no doubt opines the element of chance is a less important consideration. In South America and also in China one is forcibly struck by this view of German enterprise. The Teuton has been making tremendous strides in trade and his ships follow his trade, but seldom do we find him investing his money outside his own country in enterprises that are developing the natural resources of the places in which he is doing business, such as mines, railroads, power-plants, and the like. Trade is safer and the German has a ruthless genius for it.

As investors or speculators in mining enterprises the English are pre-eminent, they are ready to take more risks than even Americans, but at the same time they are prone to minimize these risks by employing good engineers whom they do not appear to hesitate in compensating generously. This fact, I believe, accounts in a large measure for the considerable number of American mining engineers who have been for years making their headquarters in London. Indeed since the early golden days on the 'Rand,' in South Africa, American mining engineers have been largely employed by British companies. But these conditions may not endure. Hence if we are to compete and continue to hold abroad the great reputation that American engineers have achieved, we must induce American capital to venture outside the borders of this country. Most Americans seem to have a notion that because a mine, or other investment, may be in a remote place, it is necessarily a precarious venture. There certainly is an indisposition on the part of American investors to incur the heavy expense of sending an efficient and responsible engineer to such places. The promoter is well aware of this weakness and works on it. Experienced mining concerns, of course, are not ordinarily guilty of the folly of such false economy, but the small syndicate, "our little crowd at the Club," once the plausible promoter gets the proper introduction, is very likely to succumb to the "practical miner" and believe his contemptuous references to the engineer, or what he usually prefers to denominate him, the "expert" or "professor," terms of approbrium of an ignorant and suspicious mind.

Mining Machinery Salesmen

By P. B. McDONALD

Every mining man knows several of them: intermittent callers keen to sell a new variety of rock-drill, an air-compressor, a hoist, a pump or two. Some of them the mining man is glad to see; he enjoys talking with them; others he dodges as adroitly as he can. All sorts and shapes they are, lean, bronzed, hatchet-faced fellows, fat, sleek, cigar-smoking men, young ones, old ones, wise ones, bold ones; grizzled veterans who have handled mining machinery all their lives, and who look upon the marvellous new drills, sharpeners, etc., as only incidents in a more or less changeable field, a natural enough development that is to be occasionally expected; enthusiastic young pushers who are overflowing with a professional argot and one-sided data concerning the wonderful devices that their company is bringing out, and who confide to you in a whisper that such-and-such a machine is not being advertised yet, because the demand is so overwhelming that the factory is flooded with orders, but that, as a special favor, they can get you a few of them.

Then, there is the 'expert' type. Slow-talking, ponderous dignified men, who let you see that they are straining a point or two to visit your old mine and advise you about your poor little bunch of machinery. This special type usually only comes accompanied by the regular district-salesman, being sent out from the head-office or factory for assisting on large installations or to clinch a much desired order. Some of them are impressive and interesting men to meet, who leave behind a feeling of confidence and satisfaction, men who tell you just the things you have long wanted to know in just the right manner to stick them in your mind. Others are great bores.

In the main, there are two sorts of salemen that the staff at the mine is glad to see. The elderly man who is a 'personality,' that rare, magnetic style of character which is less common now than a generation ago, men of known principles and acknowledged position who are good salesmen because they are likable and square. The other style of salesman that is universally welcome is the young or middle-aged man who really has something to say. One who informs, jokes, and understands conditions, but who does not bluster or bluff. This latter type of salesman may be a college man or he may not. Primarily he understands the machinery he sells and the men to whom he sells it. He knows how to explain to a mine superintendent or manager what they ought to know about the machinery they buy, without boring them or becoming tiresome. And he tells them other things that they are glad to hear, bits of this and that picked up in extensive traveling.

Some mining districts are found using almost exclusively one make of rock-drills, or pumps, or drill-sharpeners, due partly to the goods having merit suited to the requirements of the district, and partly to the personality of the district sales-manager.

In the copper country of Lake Superior, there was a salesman who got into a fist-fight with a miner as a result of a rock-drill demonstration; there are two or three who are famous for their 'Cousin Jack' dialect stories and are invariably invited to all banquets and festivals; there is one who is so generally liked on the Iron Ranges that mine managers and foremen in three states call him by his first name; and there is the usual sprinkling of Irishmen, some with this peculiarity and some with that.

In general it may be stated that machinery-salesmen are a younger class of men than formerly. With the advent of efficiency methods in mining, machinery is not bought so off-handedly as in the past, and the merits and demerits of different mechanical features are given careful consideration. At the same time, there are some mechanical features of which their principal advantage is that they give something to talk about or an excuse for tacking on an extra item in the price. Mechanical improvements and accessories can be overdone, particularly where the class of labor available for mining is of the temperament that believes that when a rock-drill refuses to operate the only remedy is to hit it with a hammer. Thus, young men introducing improved machinery and trusting principally to the attractiveness of the improved parts, will not always take business away from the older proved machines that, while perhaps less up-to-date, are quite satisfactory because they have been giving good results through varying conditions. There are yet miners and foremen who claim that the "old Rand slugger is the best drill of them all," in spite of its having been superseded years ago by drills that, in turn, have had their day, to be replaced by still later and faster models.

And personality is not yet dead. A mine superintendent is a very human individual; offered two machines of approximately equal merit, he will buy from the salesman who best typifies his idea of what a salesman should be. The personal qualities that count in the case of salesmen for groceries or dry-goods do not apply to the field of mining machinery, nor would the average successful hardware-drummer necessarily make a good man to sell in the mining trade. Mine superintendents, used to the peculiar exigencies of handling such balky and extraordinary problems as are involved in daily conflict with hard rock, ignorant laborers, and intermittent catastrophes, are little influenced by the arguments of men who may be excellent salesmen but know nothing of mining. A mining-machinery salesman should know something about mines as well as about machinery, and he should know about superintendents, foremen, and miners as well as understanding about warehouses and offices. He should be able to talk equally well a thousand feet underground with water dripping down his neck as in the manager's private office, and should get accustomed to conversations carried on while the other man is attending to such necessary duties as changing his boots, paying off drunken miners, or washing his face. Sometimes it is important to listen well; for knowing when to keep still may be more efficacious than much talking.

Geology of Gold Road District

By HOWLAND BANCROFT

Having recently examined some properties in the so-called Gold Road-Tom Reed mining district southwest of Kingman, Arizona, I again reviewed, and this time with more than ordinary interest, F. C. Schrader's report, 'Mineral Deposits of the Cerbat Range, Black Mountains and Grand Wash Cliffs, Mohave County, Arizona,' which report is known as Bulletin Number 397 of the United States Geological Survey, and was published at Washington in 1909. Mr. Schrader is to be congratulated upon the large area traversed by him on his reconnaissance in view of the short time at his disposal; and the detailed study which he gave to many of the properties is worthy of especial commendation.

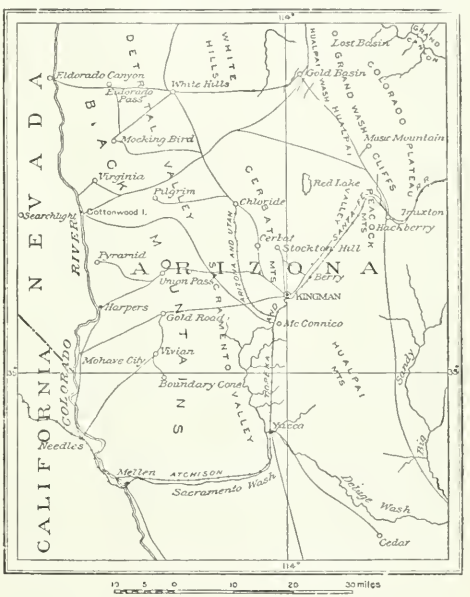
Having had an opportunity to examine but a few properties within the area covered by Mr. Schrader's reconnaissance I shall confine my remarks more particularly to the geological conditions existing in the Gold Road and Vivian districts, within which are situated two well-known properties and about which there is centring a renewed interest because of the encouraging developments on the United Eastern ground.

The entire object of this brief contribution is to help in clearing up, if possible, the rather hazy and somewhat diverse interpretations resulting from Mr. Schrader's none too lucid expression of opinion regarding the geological relationships and the influence on the productive portions of mines within the district of the formation termed by him "green chloritic andesite."

To begin with, the first portion of Mr. Schrader's statement on page 181, "So far as learned, the older andesite as a rule does not contain workable mineral deposits, except along lines where the latite has erupted through it," seems to have been more carefully studied and persistently quoted than the latter part of the sentence in which he clears up the whole situation by writing "except along lines where the latite has erupted through it." This statement is clear enough to anyone who has become thoroughly familiar with the fact that Mr. Schrader uses the terms 'latite' and 'green chloritic andesite' indiscriminately, and explains on page 196 that the green chloritic andesite (or latite) is probably an intrusive into the older andesite, whereas on page 34 he refers to the formation as a flow. This, of course, is rather confusing, and takes some detailed study to interpret his conclusions, especially in view of the following sweeping statement, on page 48: "The most favorable ore horizon seems to be formed by the green chloritic andesite, and in the underlying older andesite the veins are barren."

A study of Mr. Schrader's generalized section across the Black Mountains, on page 35, would lead one to the belief that he considered the green chloritic andesite as being primarily a flow. This may or not be so as regards the formation as a whole. However, in the vicinity of the mines that I examined, in localities rather widely scattered, I found undoubted evidence of the intrusive nature of this formation, and the orebodies are largely formed within the intrusive. Consequently, the maximum thickness Mr. Schrader allows the formation, namely, 800 ft., is not going to be the limiting depth to which the mines within intrusive masses of this material can be worked.

None of this is contrary to certain statements made by Mr. Schrader. However, it takes more than a casual study of his report to arrive at the conclusion that he is not hopelessly contradictory in his statements. It is suggested that if the operators had made a serious study of the report, followed by detailed geological work in the vicinity of the mines in which they were interested, the fear attending the sinking of each succeeding level might have been entirely eliminated and a more extensive development of the deposits, which are so evidently



MAP OF ARIZONA.

within the intrusive masses of the green chloritic andesite, would doubtless have been accomplished ere this. It is to be remarked that in the Gold Road-Vivian districts there are only two properties that have been developed to a depth of over 1000 ft., below which zone both mines are reported to be yielding commercial ore.

To summarize: Many of the veins in this district have been formed within the intrusive phase of the green chloritic andesite or at the contact of rocks which this formation has penetrated. The limiting factor to their productive depth is not going to be the maximum thickness Mr. Schrader ascribes to this formation. I do not intend to imply that all of the veins in this formation will be productive, or if productive, will remain so throughout their course in this formation; simply that the "thickness" of the green chloritic andesite has no apparent connection with the productiveness of the veins.

Concentrates

Readers of the Mining and Scientific Press are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

Wad is an earthy mixture of manganese oxides.

Wrought-iron pipe filled with good concrete makes good mine props. A disadvantage lies in the weight and placing in position.

The first stamp-milling in America was done in Georgia, which borrowed its practice from Hungary. Hungary borrowed from Egypt.

Dynamite freezes at a temperature several degrees higher than that of melting snow. A temperature of 35°F. is low enough to spoil its efficiency.

Antimonial lead commonly contains 15 to 18% of antimony, less than 1% arsenic, and less than 0.5% copper, these being the specifications imposed by the consumers.

Metal that is to be embedded in concrete should be coated with a protective paint to prevent possible damage by electrolysis, otherwise rusting starts, aided by stray electric currents.

Slaking lime produces temperatures up to 400°C., depending on the quality of the lime. At this point it is possible for wood to catch fire during slaking. Lime should not be shipped in contact with wood.

Springing a hole is an operation whereby a few sticks of high-grade dynamite are detonated in the bottom of the hole, producing an enlarged and pear-shaped opening, which can then be filled with explosive powder as required.

A crystal of calc-spar consists of carbonate of lime, it is true, if we only mean that it can be resolved into carbonic acid and quicklime; but if the same carbonic acid is passed over the same quicklime, the result is lime carbonate, but not calc-spar.

Explosion-proof is a term applied by the U. S. Bureau of Mines to motors constructed so as to prevent the ignition of gas surrounding the motor by any sparks, flashes, or explosions of gas or of gas and coal-dust that may occur within the motor-casing.

To face the glare of a furnace or to protect the eyes from excessive light, it is not necessary to use colored spectacles or smoked glass. Protection can be obtained by making a small hole in a sheet of paper or cardboard, when inspecting the furnace.

Forest and city fires create wind. During the fire at Colon, on the Canal Zone, in April, when 19½ acres of buildings was burned, the official meteorologist's records showed a total increase in the wind of from 9 miles when the fire started to a maximum of 15 miles per hour.

Nodulizing of flotation concentrate from copper ores makes pyritic smelting of the nodules possible. The cost of reverberatory smelting has been reduced to such a low figure that the introduction of this extra operation is not usually worth while.

Aluminum, when used to precipitate silver from cyanide solution, requires the addition of caustic soda just prior to precipitation. As aluminum does not even temporarily combine with cyanogen, all the cyanide thus regenerated can be at once determined by the ordinary Liebig titration.

Supposed vanadium oxide, described by Teschemaker, from the Lake Superior region, has proved to consist of Cu_2O upon careful study by W. T. Schaller. It occurs in felted masses of minute prismatic crystals, so thin that under the highest magnification the black border of total reflection covers the entire crystal.

Zinc, as much as 5 or 6% in the slag, gives no trouble in lead smelting if the lead content of the charge is low, but if the lead reaches 30 or 40% of the charge trouble is experienced. Lead smelters in Colorado and Utah average 8 to 15% lead on the charge, but at East Helena, Montana, the lead content is as much as 40%.

Explosion-dust combustion in mines is possible only when the following essential factors are present to participate in its production: (1) flame, (2) combustible dust, and (3) an air-current or draft toward the source of heat, to bring the dust and air in contact with the flame. The fineness and dryness of the dust partly determine its inflammability and ease of ignition.

The most recent improvement in connection with the utilization of blast-furnace gases consists in using the heat contained in the exhaust of the gas-engines for raising steam. In spite of the circulation of cold water in the casing of the cylinder, the exhaust gases emerge at a high temperature, and the heat contained in them may be estimated at 650 calories per horse-power hour.

Belts and ropes for power transmission are decreasing in use as direct motor-driven machinery increases. It seems that the only movement that might seriously affect the future of belts will be the general adoption of the all-electric drive with an individual motor to each machine, but this is hardly within measurable distance of realization, being too expensive an ideal. All experience seems to indicate that the system of the future will be that of grouping machines and machine-tools, the group itself being motor-driven, but the individuals operated by belting. Mistakes often occur in consequence of making the application of particular deductions general; and because individual motor-driving has been adopted with success in certain instances, the inference is not warranted that it is suitable for universal or even for general application.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

DEADWOOD, SOUTH DAKOTA

Maitland District Mines.—Oro Hondo Drill Investigations.—Hidden Treasure.—Wasp No. 2 Profits.—Bismarck Resumes.—Deadwood.—Heidelberg.

Probably the most important item of mining news, and that received with the greatest degree of popular interest, was the announcement that development was to be resumed at the North Homestake property, at Maitland, after a suspension of several years. With that end in view, work of dewatering the shaft was immediately started under the supervision of superintendent Fountain. The workings on the 200-ft. level, from which upward of $1,000,000 of ore was extracted from orebodies lying on the quartzite, have been kept drained ever since work was suspended, and the dewatering only included openings below that point. Here several veins of quartz were encountered in the schists, and although no information was ever made public regarding their value, the present activity is taken to indicate that results were encouraging.

Another property at Maitland that resumed active mining in the past few days was the Echo, where the miners were flooded in the shaft on April 29. At that time the water was removed entirely by bailing, and the flow proving too great to be handled by that method, work was suspended until arrangements could be made to install a sinking-pump, and incidentally to await drier weather, when it might reasonably be expected that less water would be found. In the meanwhile a 10 by 12-in. single-stage compressor, driven by a 30-hp. motor, has been installed. Air from this will be used to operate a No. 5 Cameron sinking-pump. It was also necessary to practically re-build the power transmission-line from the North Homestake transformer-house of the Consolidated Power & Light Co. It was necessary to cut off and re-set nearly all of the poles, owing to rotted butts, and also to place several new poles. Additional copper was also strung to carry the extra power demanded by the new compressor. The shaft will now be pushed to 200 ft., where a station will be cut and an electric station-pump installed. The shaft will probably be continued to 300 ft. before lateral work is commenced.

The Minnesota company, at Maitland, has closed a contract with Burns & Sanford to continue the adit on the Unionville claim. This adit was driven some years ago to prospect the downward continuation of a promising surface outcrop. Paralleling the formation, it reached a point almost vertically under the outcrop, but did not intersect the ore-shoot, which probably is pitching in the direction the adit was driven. This work is being watched with interest, as it may result in the company being able to resume milling.

In sinking the Oro Hondo shaft, which work is in charge of E. W. Talbot, some extremely hard ore has been encountered between the 1500 and 1600-ft. levels. This has caused some delay in sinking. The greatest difficulty was to find steel for the Jackhamers which would stand in good shape; various kinds of bits and makes of steel were tested, with the result that the Crucible Steel Co.'s product was finally adopted. On this steel are forged chisel-bits, similar to the ordinary bit used for drilling by hand; cross-bits and rose-bits of various kinds would not hold up so that a hole cou'd be drilled to the required depth. With the chisel-bit it is possible to get the maximum stock just where it is needed, behind the bit, as well as making the edges of the bit of substantial size, so that the gauge does not wear off too quickly. Mr. Talbot also says that these bits drill faster than any others tried, are cheaper to forge, and easier to handle in nearly every way. On the 1500-ft. level, where the auxiliary-hoist is placed which serves the men who are sinking, cross-cuts are being advanced in both directions from the shaft. In this work water Leyner drills are used. For sinking 'Bull Moose' Jackhamers, the heaviest type of sinker made by the Ingersoll-Rand Co., are used. The machines weigh 105 lb. This exploratory work is being done with the hope of finding the Homestake orebody on its pitch to the southeast. The shaft is half a mile from the Ellison shaft of the Homestake company; its collar is approximately 300 ft. below the collar of the Ellison. The work is being financed by J. T. Milliken, who recently disposed of his Golden Cycle property, at Cripple Creek, for a large consideration.

To secure the services of the best mechanics in the Black Hills, the Hidden Treasure company, operating on Deadwood gulch, had the 50-hp. gasoline engine which drives the hoist and compressor, taken to the Homestake machine-shop, where it was thoroughly overhauled. It has been returned to the Hidden Treasure in excellent condition. From now on it is thought that better progress will be made with the cross-cuts being run on the 200-ft. level, or bottom of the shaft.

With the declaration of a dividend of 1c. per share on June 15, the Wasp No. 2 Mining Co. made its second distribution for the current year. The previous dividend was paid in May. It was at the rate of ½c. per share. During the winter months operations at the Wasp are usually curtailed and sometimes suspended altogether. During the past winter no night shift was employed in the mine; this resulted in reducing the tonnage handled practically 50%, although the yield was more than half of normal, indicating a slightly better grade of ore and a better mill recovery. Since the night shift has again been employed the capacity has been raised nearly to the maximum of 500 tons per day. It is expected that the usual monthly dividends will be paid during the balance of the year.

Arrangements are being perfected for starting the Bismarck mine and mill at full capacity. The property recently reverted to the owner, J. A. Sandholm, of Des Moines, Iowa, the Bismarck Consolidated Mines Co. failing to make the payments on the purchase price specified in the deed and contract. The mill, which was erected by the Bismarck company, and under the contract now belongs to Mr. Sandholm, is one of the best dry-crushing plants in the Black Hills. The mine adjoins the Wasp No. 2, and contains ore practically identical in character with that property; however, it appears to be slightly lower in value. Under the direction of James Hall preliminary steps are being taken. The first work will be the construction of a skipway from the mill to the railway tracks below, over which supplies can be hauled to the mine and mill at a moderate cost. When this is completed other work will be accelerated.

At the annual meeting of the Deadwood-Heidelberg Mining Co., held at Deadwood, the superintendent, A. T. Roos, made an elaborate report covering operations at the mine during the year. Practically all work was in the nature of development, only 48 ft. being driven along the ore, in the course of which 28 tons was removed and shipped to the Golden Reward mill. This lot assayed $16.40 per ton. The shaft was completed to a depth of 193 ft.; it connects with the main adit at 135 ft. Work in the shaft was suspended until machinery could be secured and erected. Exploratory work resulted in finding a second 'vertical' in the shale, parallel with the main vertical and 65 ft. from it. At a point on the opposite side of the gulch

and about 500 ft. distant a vertical was uncovered. Since it is on the strike of the main vertical, it is believed to be a continuation of it. Good assays were gotten. During the year $4080 was realized from the sale of treasury stock. This and the proceeds of the ore shipment was all used to defray operating expenses. The directors have started a campaign to raise $6000 for the present year's operations. Shares are being quite liberally taken by residents of Deadwood and Lead. It is planned to spend the money on the upper ore horizon, to develop the verticals already in sight, and cross-cut in a search for others. No further shaft work will be attempted at the present time.

The value of the gold, silver, and lead produced in South Dakota in 1914 from 30 productive mines, 10 of which were placers, amounted to $7,431,343, compared with $7,424,333 in 1913, as reported by Charles W. Henderson, of the U. S. Geological Survey. The gold output in 1914 was 354,758 oz. fine, valued at $7,333,508, compared with 354,071 oz., valued at $7,319,294, in 1913, an increase of $14,214. The production of silver increased from 172,702 to 176,642 oz. The production of lead was only 3,897 lb. The placer-gold output amounted to only 68 oz. South Dakota has produced in 38 years from 1876 to 1914, inclusive, $185,287,640 gold and 5,832,669 oz. silver, with a commercial value of $4,213,674, a total of $189,501,314. A total of 2,019,262 short tons of ore was mined and treated in 1914, compared with 1,899,167 tons in 1913. Of this total, 2,017,882 tons was treated in the mills in the State, yielding $7,273,702 in gold and 172,574 oz. silver, with an average of $3.605 in gold and 0.086 oz. silver. The output of smelting ore (1380 tons) averaged 2.047 oz. gold and 2.94 oz. of silver to the ton. The Homestake mine and mills were operated continuously throughout the year and yielded 1,587,774 tons, which yielded bullion of the value of $6,160,161, averaging $3.88 per ton, compared with 1,540,961 tons of ore, $6,186,652 in bullion, and an average of $4.01 a ton in 1913.

CRIPPLE CREEK, COLORADO

Trail Development.—U. S. Reduction & Refining Co.—Portland.—Independence.

The Trail mine, on the south side of Bull hill, is one of the most discussed properties in the district at present. The development on the 1200-ft. level, made by Eby & Co. a short time ago, is reported as yielding ore from a vein six feet wide. Settlements so far have averaged about $20 per ton. A night shift was recently put on.

It is reported that on June 19 an adverse decision for R. E. McDonnell and associates was delivered by the Judge of the U. S. District Court in Denver. This affected the suit involving the control of the United States Reduction & Refining Co., of Colorado Springs. Mr. McDonnell was ruled against on every point of his complaint. Arthur Connell, of Colorado Springs, was made permanent receiver of the company. He has power to dispose of all property owned by it. It seems probable that the plant near Colorado Springs will be sold in the near future to the Golden Cycle Mining & Reduction Co. The cash from the sale of property, together with the money in the treasury, will probably go to the bondholders. The Reduction and Refining Co. will then go out of existence.

The air about the district seems charged with excitement, on account of the transfer of the Independence mine and mill to the Portland company. The actual transfer is to take place on July 1. It is generally expected that the new owners will commence an extensive system of mine development. The present leases in the Independence mine will be completed by the first of the month. Most of these lessees and many others have applied to the Portland company for blocks of ground under the régime. The Portland plan will furnish an interesting comparison between the split-check system of leasing and the straight royalty basis, with an added charge for profits above a stated amount. The latter system has been developed by Stratton's, while the former has been in force at the Portland mine.

Renewed activity is apparent at the C. O. D. mine. Three sets of lessees are working, two more are ready, while the new owners of the property have had numerous applications for leases. The main shaft is down over 800 ft. A good ore-shoot has been cut on No. 10 level. A 1500-ft. capacity hoist has been ordered to facilitate development and ore extraction.

Operations of the Cripple Creek Deep Leasing Co. are being followed with interest. At present it is working in the Jerry Johnson mine, which has yielded about $1,750,000 down to 650 ft. Development will be done below this point. The new 100-ton mill and cyanide plant will soon be ready.

GOLDFIELD, NEVADA

Jumbo Extension, New Goldfield Simmerone, and Goldfield Oro Developments.

The Jumbo Extension has continued shipping 100 tons daily, the product averaging $58 per ton. After July 1 the production will be at the rate of 75 tons daily. Ore of shipping grade has been exposed in drifts that have been started from the 526-A raise, the most southerly point at which the ore-channel has been penetrated. This further established the trend of the ore to the south, toward the St. Ives claim of the Merger Co. From the dip of the shale, it is apparent that the south drift following the fissure within the shale will reach the contact of shale and latite near the southern boundary line of the Paloverde claim. Raise 524-A, driven from a point near the centre of the rich 524 drift, has advanced in good ore, on the dip of the shale, for over 100 ft., and a drift to the east on the contact has exposed ore from 2 to 3 ft. wide, assaying over $200 per ton.

An interesting discovery has been made in ground belonging to the New Goldfield Simmerone company, within 2½ ft. of the old incline shaft from which early operations produced exceedingly rich ore. Superintendent Knickerbocker shot into the supposed foot-wall, 5 ft. below the surface, and exposed 18 in. of ore panning freely and estimated to assay $50 to $100 per ton. Good pannings are also being obtained on the 100-ft. level, and work on the 250-ft. level is nearing the same point of intersection of two lodes.

On the 800-ft. level of the Goldfield Oro a new water-channel has just been opened, where the appearance of the quartz is said to be encouraging. The Sandstone-Kendall Consolidated is making good progress in sinking its winze from the 500 ft. level, following the vein, and will shortly cross-cut to the hanging wall. On the 500-ft. level of the Booth, the foot-wall drift continues in low-grade free-milling ore that should ultimately be handled at a profit. Raises in the Kewanas are following seams of $10 ore from the shale-contact drifts at a depth of 840 ft. The Great Bend main-shaft is being unwatered rapidly and the old platform at the 300-ft. level, upon which a large quantity of refuse had accumulated, has now been removed.

The final report of the Goldfield Consolidated for May shows that 32,280 tons of ore yielded $161,653 net. All expenses were $5.27 per ton. Development totaled 3194 ft., at $6.56 per foot. Lessees extracted 1148 tons worth $132,283. Of this the company received $66,256, less transportation and treatment charges.

Up to June 26 the Florence had shipped 350 tons of ore for the month. The stope recently started on a new vein at 250 ft. in the old Florence Consolidated lease continues to give good results. A raise north of the stope shows 4 ft. of $20 ore.

On July 19 the Jumbo Extension company will hold its annual meeting at Phoenix, Arizona. The report for the year will soon be distributed.

A drilling contest will take place at Goldfield on July 4. A large number of miners will compete.

THE MINING SUMMARY

The news of the week as told by our special correspondents and reflected by the local press.

ALASKA

Fairbanks

In the *Fairbanks Weekly Times* of May 24 was a symposium on what it terms 'The Quartz Question' of the district. 'Optimist' argued that it was already a rich quartz camp, with a good future. Placer mining will pass out in three years. 'Pessimist' thought that Fairbanks would not make a quartz camp, the experience of nine years' work. 'Impartial Observer' considers the centre has excellent quartz prospects. It has not had a proper test. Better roads and milling facilities would stimulate quartz mining. The various properties are briefly described, showing the work under way at the Rhoads Hall, Teddy R., Crites and Feldman, Tyndall and Finn, Stevens, Mizpah, and others. A Lane mill from Los Angeles is to be installed on Fairbanks creek by C. E. Heilig. It will work with a Huntington mill.

Fairbanks business men returned from a study of the Tolovana district on May 23. They were confident that the district would turn out to be fairly good. A large number of men are busy on the creeks.

It is reported that crops of interior Alaska, especially in the Tanana valley, will be larger than ever. Potatoes look extremely well.

Juneau

The Alaska Gastineau company has 180 men employed at the Annex power scheme. A 1350-ft. tunnel is to be driven to tap Annex lake 100 ft. below water-level. An incline tramway 3000 ft. long has been completed, rising 700 ft. above the beach. The top end connects with a railway 4000 ft. long going to the tunnel mentioned.

May gold returns of the mines on Douglas island were as follows:

Details of operation	Mexican	Treadwell	United
Development, feet	359	767	1360
Lowest level, feet	1,750	2,100	2,200
Broken ore stock, tons	–16,164	–47,815	–19,878
Stamps dropping	120	540	270
Ore crushed, tons	19,320	79,832	46,179
Gold by amalgamation	$16,086	$85,676	$47,421
Gold from concentrate	13,966	83,198	48,021
Concentrate, tons	451	1,700	1,046
Average per ton ore	$1.56	$2.12	$2.04
Profit	$6,258	$77,192	$22,133

On June 19 the crank-shaft of the great hoist at the Central shaft of the Treadwell mines broke. The break occurred between the drum and disc on the left side. The shaft is 10 ft. long, 19 in. diameter, weighing 26 tons. About a month will be required to make and install a new one, it probably coming from Bethlehem, Pennsylvania. As a result of this accident the '300,' '240,' and Mexican mills are closed, and the '700' is at less than half capacity. The Treadwell and Mexican hoists are being overhauled for work.

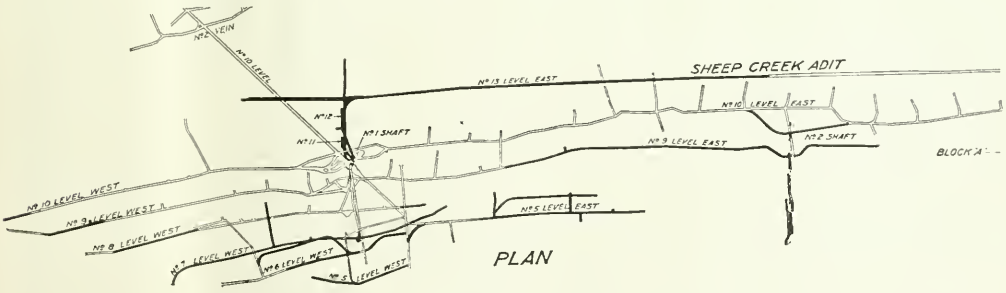
ARIZONA

Gila County

Last week the Old Dominion company disbursed bonuses to salaried employees. Starting at $150 per month the bonus was $10, $15 for $200, and $20 for over $200.

Mohave County

The vein cut at 565 ft. in the United Eastern is proving to be of considerable extent. It is 37 ft. wide, 22 ft. of which assays $36.60 per ton. Gold is visible in parts of it.——At 300 ft. in the Pittsburg the west drift is in formation similar to the United Eastern.——Extensive development is to continue at the Black Range, in charge of D. P. Wright.——A hoist, engine and compressor, and other equipment for sinking from 155 to 300 ft. is to be installed.——Kingman people are interested in the Carter mine which is opening well at 150 ft. The shaft is to be sunk to 300 ft.——The Telluride is a promising property. Cross-cutting is underway at 400 ft. depth.



PERSEVERANCE MINE, JUNEAU.

Santa Cruz County

The development company that was working at the World's Fair mine at Harshaw has turned it over to the owner, Frank Powers. Under his management sinking and driving continues.

Yavapai County

In the *Yavapai* for June the Chamber of Commerce at Prescott publishes a list of mining properties desiring capital to assist in their development. The Chamber does not know the merits of these mines. On some of them a good deal of work has been done, and equipment erected.

ARKANSAS

Mining men in this state have formed the Zinc Ore Producers' Association of Arkansas. E. Zimmerman is president.

and G. W. Chase is secretary at Yellville. The idea of the organization is to protect producers in the sale of their ore.

CALIFORNIA

In connection with Assembly Bill No. 487, known as the 'semi-monthly pay-day bill,' the attorney-general, U. S. Webb, states that if the wages earned prior to the 16th day of the month are paid on the last day of the month, they clearly come within the terms of the statute; and if the wages earned subsequent to the 15th day of the month, and prior to the 1st day of the following month are paid on the last day of the month in which they are earned, they are paid 15 days before the statute requires them to be paid.

Oil production statistics in May are as follows: rigs completed, 14; wells drilling, 138; completed, 41; abandoned, 38; producing, 5943; and yield, 7,686,517 bbl., according to the Independent Oil Producers' Agency. There was no surplus, stocks, 60,820,315 bbl. at the end of the month, being drawn on by 74,075 bbl. Figures compiled by the Standard Oil Co. vary slightly from the above. They indicate an output of 7,630,743 bbl., and a surplus of 5294 bbl. Well details also show a difference.

Butte County

The El Oro Dredging Co. has finished dredging its area at Oroville. The last boat is being dismantled. From 1904 to 1913 No. 1 boat dug 5,015,416 cu. yd. of gravel, and from 1908 to May 1915, No. 2 moved 3,789,819 cu. yd., a total of $8,805,235 yards.

Inyo County

A 21-page report with plan and illustrations has been issued by the Reward Gold Mines Co., operating in the Russ district, east of Mt. Whitney. The company is incorporated in Arizona with 1,000,000 shares at $1 each. The area is 180 acres. The mine is opened on five different levels. Approximately $270,337 in gold ore is blocked out. Reports on this ore were made by W. H. Landers, A. Burnett, and F. N. Fletcher. They estimated the gross value of positive ore at $317,046, $228,048, and $265,917 respectively. An average of the three estimates gives $270,337. The ore varies from $11.79 to $13.70 per ton. The total cost of operations is estimated at $6 per ton. The equipment and buildings, including a 20-stamp mill and concentrating plant, compressor, motors, houses, etc., originally cost $100,000. Recovery has been low, and a cyanide plant is necessary. Tests show that 90% can be recovered.

Nevada County

Considerable interest was shown in Grass Valley on June 23, when the crank shaft for the new hoist at the North Star central shaft was hauled to the mine. Twenty-four horses pulled the 23 tons of machinery, aided at one point by an electric street car.

Shasta County

Three furnaces are in blast at the Kennett smelter of the Mammoth company. A fourth is to be blown-in. Over 700 men are employed at the mine and plant. At the California mineral exhibit in the Palace of Mines at the Exposition, the Mammoth company displays ores, matte, blister copper, photographs of its works, and an excellent glass model of the mine.

It is reported that the Balaklala Copper Co.'s smelter at Coram will resume work at an early date. A court injunction closed it in July 1911. It has since been re-modeled to lessen the fume.

COLORADO

Lake County (Leadville)

The Valley adit at Prospect mountain, mentioned in the Press last week, is in 1150 ft. This work is of considerable importance.——Lessees at the Lalla Rookh and Forest City in Big Evans gulch are opening a wide vein.——A new hoist and other equipment are to be installed at the Fortune, which is to work through the Yak tunnel.——Lessees at the Humboldt and other properties are getting good results.

Mineral County

(Special Correspondence.)—It is reported that the Bachelor company at Creede is contemplating the erection of a mill to treat its low-grade ore by the chloridizing process now being successfully used in Park City, Utah. The idea is to build a mill below Creede. The ore will be brought through the Commodore No. 4 tunnel, then over the Commodore tram and to the mill in railroad cars over the D. & R. G. tracks. The Bachelor has not shipped anything for some time.

It is rumored that a plan for several of the companies to get together and pump out the ground below the Wooster tunnel, which drains the principal mines of the district is about to be consumated. They have tried to do something of this sort before, but nothing resulted.

The Creede United Mines Co. is now running the Humphreys concentrator on ore from its properties, the Happy Thought, Park Regent, etc., and is shipping lead and zinc concentrate, as well as some crude lead ore that is sorted out at the head of the mill.

The Del Monte-Chance is shipping about 4000 tons per month. ——The Commodore is being worked in a small way by lessees who make small shipments from time to time.——The Equity, which is at the head of West Willow creek, seven or eight miles from Creede, is developing a good body of ore in an east and west vein. It is handicapped by being so far away from the town and railroad.——The other mines of the district are shut down and the place is pretty quiet.

The fluorspar mine at Wagon Wheel Gap is still shut down, but may be re-opened this summer. The only market for its product, which is said to be of remarkably good quality, is the C. F. & I. steel-works at Pueblo, which has not been doing a great deal lately.

Creede, June 20.

San Miguel County

(Special Correspondence.)—Bulkeley Wells, manager of the Smuggler-Union mines, at Telluride, and associates have taken over the Humboldt, Sailor's Fortune, and Tom Payne claims, on the northerly extension of the Smuggler-Union vein on the Ouray side of the range, besides other claims in the immediate neighborhood. John B. Farish controlled the Humboldt properties for a long period, and the last operations consisted of considerable development work, for which it is understood that Pat Calhoun of San Francisco provided the money. A connection with the Smuggler-Union workings on the Marshall Basin side of the range can conveniently be made by extending the old Sheridan adit a short distance to the Humboldt workings. It is understood that arrangements will be made to treat the Humboldt ore in the Smuggler-Union company's mill at Pandora. The value of the Humboldt ore is mainly in silver, and the vein is generally quite narrow, as now exposed in the workings. In Purington's report on the Telluride Quadrangle, the Humboldt workings in their relation to those of the Smuggler-Union are shown about 200 ft. too low. H. C. Lay's name is attached to the section, but he disclaimed responsibility for the error.

Telluride, June 23.

IDAHO

Blaine County

Forty-eight tons of lead-silver concentrate from the Wilbert mine, Dome district, netted $2957. The product assayed 6.55 oz. silver and 56.65% lead. The output from now on will be 600 tons per month.

Bonner County

Caterpillar tractors with 10-ton capacity trailers have proved successful in hauling ore from the Idaho-Continental mine to Porthill on the railroad, a distance of 26 miles. Three more engines are to be ordered. Regular shipments of ore are to be made to Salt Lake City. The mine is well opened for production.

Shoshone County (Coeur d'Alene)

As a result of the high price of zinc the Interstate-Callahan made a profit of $175,000 during the week ended June 12. The weekly output is 1400 tons of concentrate assaying 50% zinc, and 100 tons of 50% lead. A special dividend is likely for August, when the quarterly amount is due.

Negotiations on the smelting contract between the Hercules company and the A. S. & R. Co. were held at Spokane on June 22, and at Wallace on the next day. Nothing was agreed upon.

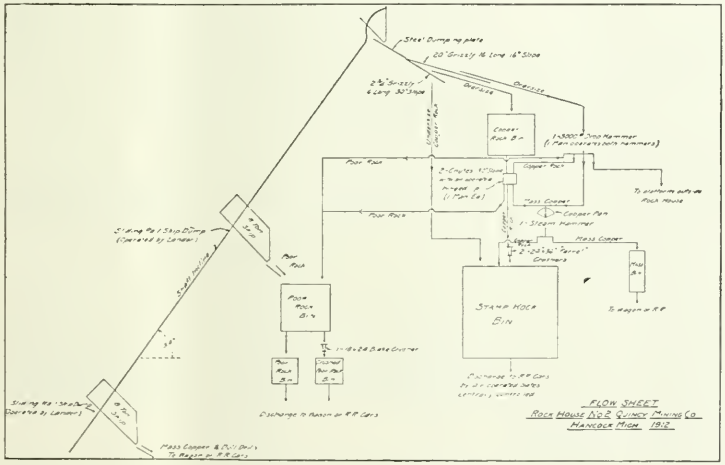
On June 23, H. F. Samuels, president and general manager of the Success Mining Co., sold his $1,100,000 shares (total capital 1,500,000 shares) to Duluth people for about $1 per share, cash. J. F. Howarth and P. J. Gearon of Wallace negotiated the transaction. The mine is at Nine Mile, near the Interstate-Callahan. A 200-ton mill is treating lead-zinc ore. Dividends are being paid, the total being $1,050,000. On June 23 the cash balance was $136,826. There is also on hand 800 tons of zinc concentrate worth $100,000.

MICHIGAN

The Copper Country

The White Pine Extension Copper Co. has been formed by Detroit people headed by S. L. Smith, with a capital of 150,000 shares. The mine is said to be opened by 6000 ft. of workings, proving the lode extension from the White Pine, which is now producing copper. Drilling in the Extension has given very uniform results.

Drilling at Cliff has been resumed by the Calumet & Hecla. Rich amygdaloid formation has been opened at 900 ft. in the New Arcadian.



Flow-sheet, Quincy No. 2 ore-house.

MISSOURI

Jasper County

On June 24 three new mining laws became effective in this state. One provides that every mine employing 10 or more men must have water handy for laying dust. The other two enforce sanitary drinking devices and sanitary change-houses.

From the top price of $135 per ton paid for 60% zinc concentrate in the previous week, the price last week varied from $128 to $90, the widest range on record. Calamine was quoted at $55 to $65 per ton. Lead was unchanged, $72, basis of 80% metal. The averages were $110.32, $61.69, and $71.61 respectively. The output was 9,831,360 lb. blende, 1,003,120 lb. calamine, and 1,290,240 lb. lead, having a total value of $629,355. Last week the value was $1,048,349.

The O. L. F. mine at Duenweg, offered for sale six months ago for $8000, was disposed of last week for $125,000. A 250-ton mill is included. Some rich zinc ore has been opened.

The two men who were entombed in the Longacre-Chapman mine two weeks ago, with others who were rescued, have been found dead.

MONTANA

Jefferson County

(Special Correspondence.)—Arrangements have been made whereby the Comet mill will be started on tailing that has lain there for over 20 years. Sampling and testing has been done. It is probable that a flotation process will be used. This is working at the old mill at Basin.

Little is being done at Elkhorn since the Longmaid interests suspended work on the old Elkhorn silver mine. The district offers a choice of ores to suit all miners. Though no small amount of attention has been given the place by engineers during the past two or three years, financial conditions have been against completion of the several transactions under consideration.

Boulder, June 10.

Lewis and Clark County

The Helena mining region is more active than for years. Work of the Helena Mining Bureau is greatly responsible for this. The Bureau has spent $10,319 in 13 months in its promotion work. On June 1 it had a balance of $2928. As nearly as can be ascertained the number of men employed in Marysville, Bald Butte, Scratch Gravel, Helena, Unionville, Rimini, Wickes-Corbin, Lump gulch, Clancy, Winston, York, and other districts aggregates 700, and is on the increase.

A new furnace of 275-ton capacity has been blown-in at the East Helena smelter. Seventy-five additional men are employed. A fourth furnace may be started in August. Three furnaces are now treating 750 tons per day.

Silverbow County

Illinois people have decided to invest $50,000 to $75,000 in the Butte and Great Falls mine in Dixie gulch. The shaft is down 350 ft. Water at 300 ft. forced the suspension of work. This level is to be unwatered, the shaft deepened, and a hoist and compressor, etc., installed. B. Green is in charge.

At the Butte-Ballaklava 90 men are employed. The output is up to 200 tons per day, going to the Washoe smelter.

Yellowstone County

About 15 teams from Montana mines will compete at the first-aid contests to be held at Billings on July 23 and 24.

NEVADA

Humboldt County

The Friedman adit, being driven in Nenzel hill at Rochester to cut the veins at a depth of 1200 ft., is in 750 ft.——At the La Tosca mine, six miles from Rochester, the Humboldt Consolidated has its adit in 2000 ft. This is expected to cut the veins at 1000 ft. depth. Important developments will probably occur shortly.

Lincoln County

On July 6 the 100-hp. electric plant at the Prince Consolidated at Pioche will be started. The winze below the 550-ft.

level is down 100 ft. High-grade shoots were cut. Ore extraction and loading ore on trains at Pioche costs $1.21 per ton.

Mineral County

The Nevada-Regent Mines Co., backed by Jesse Knight and others of Utah and Nevada, has been formed with a capital of $100,000. The company has secured 18 claims in the Regent district, now worked by lessees. A shaft is down 100 ft. on a vein 18-in. wide at the surface. At 60 ft. it is 15 ft. wide, averaging $25 per ton in silver. The lessees have stoped 1000 tons above 60 ft., and expect 4000 from there to 100 ft. The company will sink a shaft to cut the vein on its dip at 250 ft. vertical.

A correspondent in the *Western Nevada Miner*, of Mina, states that well known engineers have been examining the Rand district. Three properties have already shipped ore worth $60,000. Estimates place the reserves in the mines at $100,000, and several thousand tons on dumps. Down to 250 ft. the Last Hope has produced $30,000. The Golden Pen is down 200 ft. The last car of ore assayed $600 per ton. Prospects are excellent. Tonopah people are negotiating for this mine. The Queen Regent is in the centre of the district. A wide vein has been cut at 70 ft. depth. A hoist has been erected, and sinking will continue to 500 ft. This and the Last Hope company contemplate erecting a mill. The Mims claims have been acquired by J. E. Kerr of San Francisco.

Nye County

Last week's output of companies and lessees at Tonopah totaled 10,642 tons worth $217,570.——The Belmont shipped bullion and concentrate valued at $145,000.——On July 21 the Tonopah company will pay $250,000.——In May the Extension made a profit of $43,223.——The Tonopah East End Development Co. has issued a report for the year ended May 31, 1915. The shaft is down 440 ft. Water lately has flowed up to 30,000 gal. per day. Motor-driven pumps have been ordered. Cash amounted to $250. To continue operations the company will sell 300,000 shares.

On June 24 hydraulicking started at the Round Mountain company's deposit at Round Mountain. It took 2 hours 50 minutes for the water to fill the 8 miles of pipe. The line is holding well. There were no leaks.

At Volcano last week, miners in a shaft at the McCarthy and Mooney lease broke into a fissure at 55 ft. It is from 18 in. to 12 or 14 ft. wide, while its depth is unknown yet. The shaft is in porphyry and andesite. The walls of the cave are carbonate of lime.

The new 200-ton mill at the Monitor-Belmont at Belmont, 50 miles north of Tonopah, will be complete early in August. It is being erected next to a dump of 50,000 tons of 16 to 18-oz. silver ore. The plant includes ten 1600-lb. stamps and a 6 by 10-ft. tube-mill. Concentration will be done by flotation. Norman E. Smith is superintendent. Three shafts are down 600, 750, and 1100 ft. respectively; also two adits 1000 ft. each. The formation is mainly slate-granite contact. The ore is quartz.

Storey County

According to Charles Butters, the plant at Six-Mile canyon is to be re-started in charge of C. Morris. The tailing near the mill is to be treated.

A dredge is to be erected by H. E. Ray of Dayton on ground between Dayton and Virginia City. A large yardage of rich gravel is said to be available.

UTAH

Juab County

Shipments from Tintic last week totaled 185 cars of ore.

The formation of a company to treat custom ore at Tintic has been mentioned in this journal. The Tintic Milling Co. has been organized with a capital of $30,000. It will purchase the assets of the Knight-Christensen Metallurgical Co. at Silver City and the Mines Operating Co. at Park City, and construct a chlorination plant at the site of the old Knight smelter at Silver City. The officers of the Tintic Milling Co. are Jesse Knight, president; George H. Dern, vice-president and general manager; W. Lester Mangum, secretary and treasurer, and Theodore P. Holt, general superintendent. Besides taking over what is left of the Knight-Christensen plant which was burned several months ago, the new concern also takes over the contracts that the company has for treating ores of the Knight mines, including the Beck Tunnel, Colorado, Black Jack, Iron Blossom, Salvadore, and Dragon Consolidated. The Knight interests will own practically 51% of the new company and George H. Dern 49%, although the management will be retained by the later. The construction of the plant has already started and it will begin operations with a capacity of 300 tons of low-grade ore a day. This will probably be increased later. The Mines Operating plant will be dismantled at once and moved to Tintic.

Electric power is gradually displacing steam in this district, especially for hoists. The Utah Power Co. supplies the current.

Summit County

The Silver King Consolidated is shipping 100 tons of ore daily. It averages 50.4 oz. silver, 0.0514 oz. gold, 28% lead, and 1.291% copper. Development, especially at 1700 ft., continues very satisfactory.

The Ontario Silver Mining Co. has issued a statement for 1914. Little was done during the year. Work was resumed in May of 1915. The present output of ore is about 600 tons per month. Some of it is high in silver, up to 100 oz. per ton, and 9 to 10% lead. The revenue was $33,712. Cash and investments total $323,379. Ernest Bamberger is general manager.

Utah County

Machinery, rails, cars, lumber, etc., has been hauled to the Pittsburg Mining Co.'s mine at the head of American Fork canyon. A good deal of zinc and lead-silver ore has been opened.

WASHINGTON

Ferry County

In the intermediate and lower level of the Knob Hill mine at Republic, 4 and 7 ft. of $20 and $50 ore respectively has been opened. A year ago 11 cars of ore from near this point were worth $55,000. The weekly output at present is two cars, returning $2100 per car. Sixteen men are employed. The company has paid off its debt, and is building up a surplus.

Stevens County

The first unit of the new stamp-mill at the United Copper mine in the Chewelah district, 60 miles north of Spokane, was started last week. It is treating 150 tons of ore per day and producing about 10 tons of high-grade concentrate, according to Conrad Wolfe, the manager. The mill is giving satisfactory results. Work is progressing well toward the completion of the additional unit, which will bring the capacity up to 350 tons per day. About 125 tons of crude ore and 25 tons of tailing is handled every day. A station is being cut at the 1000-ft. level in the shaft. Hoist equipment will be installed of sufficient capacity to sink the shaft another 1000 ft. making a depth of 2000 ft. Sinking will continue as soon as the power company is able to deliver additional power from its plant at Meyers Falls. This will be about September 1.

VIRGINIA

Norfolk County

(Special Correspondence.)—The Virginia Smelting Co., which operates a plant at West Norfolk, Virginia, is making a number of alterations. Under guidance of Utley Wedge, a chloridizing plant is being built for treatment of Eustis fine cinder and other pyrite cinder that has been sintered. The product from the Wedge 5-hearth Rameu Beskow furnaces

will then go to leaching vats for treatment by the McKay process. Mr. Wedge is also building a plant for the commercial production of SO_2 consisting of hot-wells, scrubbers, lime-towers, and heat-exchange units. This will wash all gases coming from blast-furnaces and converters, and is expected to produce a product of some value. E. C. Vigeron has gone there as manager.

West Norfolk, June 20.

CANADA

Alberta

(Special Correspondence.)—The Southern Alberta Oil Co. has encountered oil in large quantities at a depth of 3527 ft., two miles north of the Dingman well near Calgary. The company will put down a second well in the same neighborhood.

Calgary, June 20.

Ontario

(Special Correspondence.)—The contracts between the Timiskaming and Beaver companies and the Northern Ontario Light, Heat & Power Co. for supply of electric power expired on June 1. The power company submitted new rates, increasing the price about 50%. The companies have refused to accept these terms and the question is in dispute.——The Timiskaming & Hudson Bay company has let a contract to David Craig for 600 ft. of driving at the 238 and 330 ft. levels on its property south of the McKinley-Darragh. The drift will be in the conglomerate along the Cobalt Lake fault.

At the Lake Shore mine, Kirkland Lake, the vein has been found to be very rich at the contact between porphyry and conglomerate, but the grade is not maintained elsewhere.

Development at the Gibson claim on Goodfish lake, near Kirkland Lake, at 80 ft. shows two distinct veins. One is about 24 in. and the other 12 in. wide, showing some visible gold. The property is under option to a New York syndicate, with whom Frank Loring, now in charge, is associated.

Cobalt, June 20.

In May the Dome mine produced 26,000 tons averaging $4.28 per ton.

On July 15 the Crown Reserve will distribute $53,064, making $6,102,363 to date.

MEXICO

It is reported that the American Smelting & Refining Co. will blow-in its smelters at Monterey and Matehuala. At Chihuahua there are four furnaces in blast. The Aguascalientes plant is still shut down.

Sonora

For some time the Moctezuma Copper Co. at Nacozari, has sold food and supplies to small properties in the district. On account of the railway to Douglas being stopped, the company finds it cannot sell any more material. Regions south of Nacozari are very short of common necessities.

PHILIPPINE ISLANDS

During April the Philippine Dredges, Ltd., had the following output:

Boat.	Cubic yards.	Average per yard, cents.
No. 1	37,850	22
No. 2	48,897	26
No. 3	58,569	18
No. 4	60,000	12

The total gold recovered was 1868 oz., a record.

The Utah section of the A. I. M. E. will have an excursion to the Tintic district on July 15. Several mines will be visited. Papers to be read are from G. W. Crane, 'Geology of Ore Deposits and Geological Methods Applied to Mining in the Tintic District, Utah,' and D. A. Lyon, 'The Zinc Problem in the Treatment of Low-Grade Zinc and Zinc-Lead Ores.'

PERSONAL

J. D. Hubbard has returned from Butte county.

H. W. McFarren is here from Santa Fé, New Mexico.

W. J. Loring has returned to San Francisco from New York.

C. W. Purington is returning to the Lena goldfield, Siberia.

J. S. Diller was in San Francisco and has gone to Mt. Lassen.

R. W. Pringle is consulting engineer to the Central Rhodesia company.

W. S. Hopper was in San Francisco and has gone to British Columbia.

A. Chester Beatty has moved his office to 25 Broad St., New York.

G. H. Garrey was here from New York, on his way to Tuolumne county.

Fred C. Alsdorf is in New York, but expects to leave for Los Angeles shortly.

E. C. Vigeon is now manager for the Virginia Smelting Co., at West Norfolk.

W. H. Dawe has been elected president of the Transvaal Chamber of Mines.

B. B. Gottsberger, general manager for the Miami Copper Co., is on a fishing holiday in California.

Charles F. Willis has been appointed director of the Arizona State Bureau of Mines.

R. Gilman Brown, Deane P. Mitchell, and Leslie Urquhart were delayed in going to Siberia, but are starting now.

E. F. Burchard has been selected as geologist in charge of non-metals section of the division of Mineral Recources, U. S. Geological Survey.

W. L. Honnold has resigned his connection with the Brakpan and Springs mines, at Johannesburg, and is returning to the United States.

Edgar Newhouse, C. W. Whitley, H. A. Prosser, W. H. Howard, Willard S. Morse, Roger Strauss, and William Loeb of the A. S. & R. company are here on a tour of inspection.

Schools and Societies

The Michigan College of Mines *Theta Tau* fraternity, an engineering association, principally mining, will hold a convention, the third biennial, at the University of California on September 8 to 11.

The American Mining Congress announces from its offices in Washington that its next convention, which will be the eighteenth, will be held at San Francisco on September 20, 21, and 22, the meeting immediately preceding that of the American Mine Safety Association which will take place on September 23 and 24, and following the International Engineering Congress on September 20. The chief topics of discussion of the Mining Congress will relate to the Western public-land problems and legislation, now so conspicuous in the legislation of the National Congress at Washington.

The School of Mines of Western Australia, at Kalgoorlie, under the Government Department of Mines, has issued its syllabus for 1915, and annual report for the year ended December 31, 1914. The publication covers 105 pages and is well illustrated with pictures of the institution. The staff consists of nine instructors and five laboratory assistants. The attendance in the three terms of 1914 was 594, 514, and 403, respectively. Thirty-nine, seventy-one, and eighty-eight students passed respectively the first, second, and third classes in 22 subjects at the examinations in November. The school is excellently equipped for all practical instruction. Good prizes and scholarships are offered.

THE MARKET PLACE

Weekly Summary of Metal Prices and Notes on the Markets.

Metal Prices

San Francisco, July 1.

Antimony	35 —35⅝
Electrolytic copper	20½—20¾
Pig lead	6.00— 6.95
Quicksilver (per flask)	$85
Spelter	22 —22¼
Tin	41 —42½
Zinc-dust, 100-kg. zinc-lined cases	30

Supplies of zinc-dust are small.

EASTERN METAL MARKET
(By wire from New York.)

NEW YORK, July 1.—Copper is quiet, the quotation is nearly nominal; re-sale lots of lead are disappearing; the demand for spelter seems likely to increase.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.		Average week ending	
June 24	48.75	May 19	49.93
" 25	48.50	" 26	49.77

The weakness in silver continues. On June 26 about 410,000 oz. left San Francisco for China. On June 22 the Nipissing company dispatched 250,797 oz. to New York. To this date of 1915 this mine has sent 3,137,942 oz., valued at $1,554,155 to London. Some went direct, the remainder by way of New York.

Writing on June 10, Samuel Montagu & Co. say that selling on China accounts for depressed prices. Not much weight is attached to advancing prices, when they are the outcome of a shrinkage in supplies. It has been rare for any silver to be offered for sale in the afternoon, and when the market is small, the close of each day is likely to be accompanied with a hardening tendency. Inquiry has arisen from the Indian Bazaars, but not of an extensive character. The Continental demand has also been slight. Buying at the present time is not hearty enough to insure an impression of confidence whenever supplies become normal as to quantity.

ZINC

Zinc is quoted as spelter, standard Western brands, St. Louis delivery, in cents per pound.

On July 7 the New Jersey Zinc Co. meets to increase its capital from $10,000,000 to $35,000,000.

Twenty-seven tons of 63.5% zinc concentrate sold at Joplin three weeks ago has been settled for at $139.90 per ton, the highest ever paid in the region.

A London metal house, writing under date of June 11, says: "The event of the week has been the announcement by the Munitions Committee that it contemplates issuing instructions to commandeer all spelter other than that being used for cartridge making, and to prohibit its use for galvanized sheets and work other than for war purposes. This official announcement caused some perturbation on 'change among dealers, who naturally wondered how they stood with regard to existing contracts. A little later, however, it was announced that business was to be carried on as usual in the metal, and it seems to us, therefore, that all contracts made will stand for the present."

COPPER

Prices of electrolytic in New York, in cents per pound.

Date		Average week ending

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending

ALUMINUM

The market is strong at 31 to 32c. per pound.

Eastern Metal Market

New York, June 25.

A quiet week has brought about easier prices in nearly all the metals. In copper and spelter the situation may change radically at any moment. Despite concessions by others the larger copper producers are firmly holding to 20.50c., 30 days, delivered, for electrolytic. The feeling is that the War demand will be renewed in force in the near future. After dropping to 18c., spelter has steadied, and gained a little strength from export demand. Zinc exports are shown, by Government figures, to have increased heavily. The U. S. Steel Corporation has contracted for a year's supply of Australian zinc ore for its new plant to be built at Donora, Pennsylvania. Lead has declined, until offerings of 5.45c. or less, have been made, although the A. S. & R. Co. continues to quote 5.75c. Consumers who bought beyond their needs on the rise and later attempted to sell have been disappointed. Tin has been quiet. Antimony continues strong and sales are reported. Aluminum is a little higher.

The War demand continues the dominating feature of business in the East. For some classes of metal-working machinery, such as turret-lathes, automatic screw-machines and engine-lathes, orders representing hundreds of thousands of dollars have been declined by the manufacturers, who are so loaded up with orders that they cannot make the deliveries desired. Machinery for rolling brass is being ordered from England.

COPPER

The market has been quiet and a little weakness has developed in prices as quoted by one or two smaller producers and by second-hands. The larger producers have held to 20.50c., 30 days, delivered, or 20.37½c. cash, New York, on the theory that the requirements of manufacturers of war munitions are not yet satisfied. As a matter of fact, good-sized inquiries have come out in the week which have not yet been consumated by sales. Throughout the week copper could be had at 20c., although any considerable buying would have quickly sent prices up. Prime grades of Lake are quoted at 22.50 to 23.50c., although brands suitable for many purposes can be had at 20 to 20.50c. Not only the attitude of the producers, but the general conditions indicate that the market is healthy. Exports up to June 25 totaled 13,890 tons.

SPELTER

Dullness without interruption and a steady decline was the case with spelter for some days. The quotation reached 18c., June 22. It has since hovered there, indicating a growing steadiness. The situation was helped along by a moderate amount of export buying. The decline referred to was entirely in prime Western, the higher grades, or brass-mill special, holding their own in a nominal market. Justification for a strong market appears in the figures showing the April exports and those of the 10 months ended April, as issued by the Bureau of Foreign and Domestic Commerce. In April the exports of domestic spelter in pigs, bars, plates and shapes amounted to 17,683,173 lb. against 120,149 lb. in April, 1914. In the 10 months ended April 1915, the exports totaled 222,478,162 lb., compared with 3,243,418 lb. in the same period of 1914, and 4,997,680 lb. in 1913. It will be noticed that the 10 months ended April, 1915, go back one month prior to the War. These figures are taken as a 'bull' influence, but the trade does not so construe the suggestion of the Munition Commission of England that it might prohibit the use of spelter for galvanizing in that country. The idea, of course, is to conserve the supply for war needs. The exports of spelter of foreign origin in April totaled 153,561 lb., bringing the total for 10 months to 17,451,565 lb. The exports from June 1 to 25 totaled 1569 long tons.

The plan of the U. S. Steel Corporation to build a smelter at Donora, near Pittsburg, is pronounced a wise one. Some point to the possibility of the corporation selling some of its product to outsiders. Again, it is said that by the time the Corporation has the smelter in operation it may find that it can buy spelter cheaper in the open market. The entire matter is one of conjecture. The Corporation brings tin from the Far East in its own ships, and is largely independent of the domestic tin market, and probably desires to be equally as free in the matter of zinc. Since the outbreak of the War a number of small smelting companies are reported to have been formed, but it is a question how they will fare after the present abnormal conditions pass. The initial capacity of the new Corporation smelter will be about 40,000 tons per year, which is about the amount by which its present production of spelter would fall short were the galvanizing operations of the American Steel & Wire Co., the American Sheet & Tin Plate Co., and the National Tube Co. to be run at full capacity. Through its subsidiary, the Edgar Zinc Co., which is tributary to the American Steel & Wire Co., the Corporation is a producer of spelter. Contracts have been closed for a 12 months' supply of Australian zinc ore for the new smelter.

Sheet-zinc was reduced April 22, to 27c. base, f.o.b. mill.

LEAD

The market has been demoralized, and the range of prices has been wide. On June 17, the largest interest was quoting 6.25c., New York. On June 18, it dropped its price to 6c., and June 19, it came down to 5.75c., which it continued to quote for several days, despite the fact that outsiders were asking down to 5.45c. It would have been natural for the high and low prices to have drawn more closely together, but they had not done so up to June 24. A peculiar phase of the market was the many offerings by consumers who had contracted for more than they needed in the panic which prevailed when prices went to over 7c. per lb. It is estimated that thousands of tons were taken at between 6.50 and 7c. Most of the would-be sellers found little or no acceptance for the metal they offered. It is now seen that consumers bid the market up on themselves and the producers took advantage of a situation most profitable to them. Independent producers were supposed to be sold up, but the market was too tempting for them to forgo selling. In the excitement of the rapidly advancing market, the independents asked and obtained higher prices than those of the Trust. Following the break, they asked lower prices, while still lower prices were asked by consumers, dealers and jobbers. Independent sellers of lead, June 25, advanced their asking price from 5.45 to 5.75c., New York, thereby putting their quotation on the same level as that of the A. S. & R.

The exports of lead between June 1 and 25 totaled 6586 tons (tons of 2240 lb.) The exports of domestic lead in four months of this year totaled 33,292 tons, against none in the same period last year. The April exports totaled 17,755 tons. According to a cable from London, the A. S. & R. Co. has withdrawn from the English syndicate which regulated the sale of lead abroad. It is understood that the company will conduct its business independently of the syndicate.

TIN

The week has been uninteresting in this metal. Trading has been dull, and the price declined until on June 23 it was 41c., where it stood also the following day. The highest daily average reported in the week, June 16 to 23, was 41.50c. The market was unquestionably affected by the slump in lead and spelter. The arrivals up to June 25 were only 2110 tons. There was afloat on that day 6502 tons, a good part of which was scheduled to arrive in the month. Meanwhile consumers are comfortably supplied.

Current Prices for Oils and Candles

(Corrected monthly by Standard Oil Co., California.)

All prices are f.o.b. San Francisco except where otherwise specified, and are subject to change without notice.

Granite Mining Candles.	Per set, cents.	Granite Mining Candles.	Per set, cents.

Manganese ore, oxide, crude, per ton	10.00	15.00
Manganese, prepared, according to quality, per ton	50.00	75.00
Mica, according to size and quality, per lb	$0.05	$1.00
Molybdenite, 95% MoS_2, per ton	1000.00	1500.00
Monazite sand (5% thoria), per ton	150.00	200.00
Nickel metal, refined, per lb	0.45	0.60
Ochre, extra strength, levigated, per 100 lb	2.00	3.00
Osmiridium, per oz	30.00	40.00
Platinum, native, crude, per oz	30.00	45.00
Silex lining for tube-mills, per 2240 lb	35.00	45.00
Sulphur, crude, per ton	25.00	30.00
Talc, prepared, according to quality, per ton	20.00	50.00
Tin ore, 60%, per ton	425.00	450.00
Tungsten ore, 65%	*450.00	540.00
Uranium ore, 10% min	25.00 per unit	
Vanadium ore, 15% V_2O_5, per ton	150.00	180.00
Wolframite (see tungsten ore).		
Zinc ore, 50% up, per ton	subject negotiation	

Current Prices for Chemicals

(Corrected monthly by Braun-Knecht-Heimann Co.)

Prices quoted are for ordinary quantities in packages as specified. For round lots lower prices may be expected, while in smaller quantities advanced prices are ordinarily charged. Prices named are f.o.b. San Francisco and subject to fluctuation. Other conditions govern Mexican and foreign business.

	Min.	Max.
Acid, sulphuric, com'l, 66°, drums, per 100 lb.	$ 0.80	$ 1.10
Acid, sulphuric, com'l, 66°, carboy, per 100 lb.	1.25	2.00
Acid, sulphuric, C. P., 9-lb. bottle, bbl., per lb.	0.13	0.18
Acid, sulphuric, C. P., bulk, carboy, per lb.	0.09½	0.12

The marketed production of phosphate rock in the United States in 1914 was 2,734,043 long tons, valued at $9,608,041. Compared with the production of 1913, which was 3,111,221 tons, valued at $11,796,231, there was a decrease amounting in quantity to 377,178 tons, or 12%, and in value to $2,188,190, or nearly 19%. As compared with 1912 also there was a decrease in 1914 of 8% in quantity and of nearly 18% in value. The production of phosphate rock has been steadily increasing for many years, with an occasional exception, until 1914, when, for causes chiefly outside the country, a diminished output has to be recorded.

EDITORIAL

T. A. RICKARD - - - - Editor THOMAS T. READ - Associate Editor

CAUTION marks business policy in general. Money is not in demand. Hesitation is still manifest, despite good crop prospects and a slight improvement in railroad earnings. The trend of events favors the mining industry.

PLATINUM export in quantities valued at over $250 was placed under an embargo by the Russian government early this year, in the expectation of encouraging the opening of domestic refineries. This hope has been falsified; the producers have platinum they cannot sell, and are now petitioning for a modification of the embargo.

POTASH SALTS are much needed for making fertilizers. In 1914 the United States imported $8,743,973 worth. Other ingredients of fertilizer manufacture to the value of $25,000,000 more were imported during the past year. Potash salts have been found lately in Arizona and Oregon, but the extent and quality of the deposits are yet to be proved.

GOLD from the South African, the West African, Indian, and Australian mines is being accumulated near the places of production, for the British government arranged early in the War to advance 97% of its value to the companies producing it, the payment being made in London. This gold, on the average production, represents about $28,000,000 per month. If it had been stored for the 12 months now nearly past, it would represent a sum of $336,000,000.

WE READ of a party of miners working the Sultana mine in Utah who had not kept informed concerning the metal market, so that after two months' operations they returned to Salt Lake City to find that the lead in their ore had risen from about 4 to 7 cents per pound during the interval. Fortunately they had benefited by ignorance. Another time they might suffer as much for the same reason. We commend our page, published weekly, on the metal markets to the operators of mines as giving reliable information on a subject vital to them.

ANTIMONY, in the form of the sulphide, stibnite, is plentiful in Kern county, more especially in San Emidio canyon, also near the Tehachapi pass, and at Mohave, which is just over the line in San Bernardino county. In 1884, S. Boushey and his associates worked the San Emidio mines, and subsequently Starr & Mathison built a refinery in San Francisco to treat the product. This refinery was operated for several years and only failed because of the prejudice for 'star' metal, although that produced in the local plant was identical in character. So the antimony had to be shipped to New York, and the freight killed the business. In California antimony is associated in nature with mercury; hence it is also found in Napa, San Benito, and San Luis Obispo counties.

BALANCES of trade have averaged $140,000,000 per month in favor of the United States for the last seven months. Despite the liquidation of American securities in Europe, about $120,000,000 of gold has crossed the Atlantic to balance the account. Further selling of American investment stocks is certain, with a corresponding influx of gold hither. This fact is now engaging the serious study of financiers, for it is feared that it may lead to a dangerous inflation. The recognition of the danger is a good sign.

WE take pleasure in publishing an article by Mr. E. Gybbon Spilsbury giving our readers some of his technical reminiscences. If he had not confessed to being engaged on the inspection of a mine on the day when the present writer was born, we would not have disclosed the fact that he is indeed a veteran, although we were fully aware that for 50 years he has commanded the respectful attention of his professional friends. Mr. Spilsbury has the secret of a youthful spirit: the ability to take an interest in the affairs of others. His many friends will be delightfully reminded of him by reading the article and will join with us in wishing him continued health and prosperity.

TIN-SMELTING will soon be a domestic industry. As stated in our correspondence from New York recently, the American Smelting & Refining Company has a plant under construction at Maurer, New Jersey, while Williams, Harvey & Co., the principal English smelter of Bolivian ore, has announced that it also will build a smelter somewhere in the United States. We are glad to add that a proposal is on foot to build a smelter in California, to treat Bolivian ores as well as the tin concentrate from Alaska. The principal use of tin is the making of tin-plate, which is used mainly in the making of cans for preserved fruit, foods, and oils. California, with its great petroleum output and fruit-growing industry, furnishes a large market for tin-cans, as does the salmon of Alaska, and the pine-apples of Hawaii. There is thus a local market for tin products, but a tin smelter would need as a corollary a tin-plate

mill. Probably the one would be built if the other were in existence. Crude oil is available here at a low price for smelting the ore, and the development of this local industry seems quite feasible.

PAN AMERICAN Scientific Congress is the name of an international meeting convened for December 27 next at Washington. It is a sequel and a confirmation of the recent Financial Conference, which appears to have paved the way for closer industrial relations between the Americas north and south of the equator. That was a business men's affair, while the forthcoming Congress is to be educational and scientific. A similar convention was held at Santiago, Chile, in 1908, and at that time Washington was designated as the next place of meeting. Among the departments of science to furnish subjects for discussion is one entitled 'Mining and Metallurgy,' in charge of a committee of which Mr. Hennen Jennings is chairman. That fact speaks for itself. We make mention of this convention early so that those finding it convenient to be near Washington at the end of the year may arrange to be present and to participate.

LOCAL papers have stated that Mr. H. C. Hoover "will take over the management" of the Oroville Dredging company. This error is due to confusion with Mr. Theodore J. Hoover, his brother, who is a director of the company mentioned. However, even then the published statement would be erroneous, for the change made recently, whereby the control has passed from San Francisco to London, is of a nominal character. The fact is that the company's alluvial property at Oroville is nearly worked out; the enterprise was rejuvenated, about three years ago, by the exploitation of a new dredging property, called the Pato, in Colombia. This is doing well, but as 90% of the Oroville shares are held in London, the Californian interest in this South American dredging ground is slight, although it is pleasant to note that the technical work is still in the hands of Californians, notably Mr. W. A. Prichard, who is consulting engineer to the Pato. This offspring of the Oroville has itself given birth to a later subsidiary called the Nechi, another dredging enterprise in the same district as the Pato. It is obvious therefore that the original financial and technical interests of the original Oroville dredging company have passed elsewhere, and with this passing goes the management. It is the logic of events, nothing more.

EXAMINATION of metals by means of X-rays has been developed in the experimental laboratories of the General Electric Company, and Mr. W. P. Davey will present a paper on the subject at the International Engineering Congress, to be held in this city in September. While a radiograph gives no information as to the crystalline structure of the metal, it serves to indicate the presence of blow-holes, slag inclusions, porous spots, and similar defects that could not otherwise be detected except by cutting into the metal. Thus, for example, plates $\frac{3}{8}$ inch thick, welded by means of an oxy-acetylene flame were examined and defects in the weld easily detected. In steel $\frac{5}{8}$ inch thick an air inclusion only 0.007 inch wide could be discovered. Unfortunately none of the fluorescent screens now in use are sensitive enough, so that all the work must be done photographically. On account of the length of exposure required with X-ray tubes of the voltages now in use it is not practicable to photograph through greater thickness than $\frac{1}{2}$ inch, but with further development, higher voltages may become feasible.

COST of living in South Africa, so it is claimed by the Labor Union on the Rand, has increased to such an extent as to warrant a demand for a 20% rise in the wages paid to contractors and a 25% rise for day's-pay men. The demand comes at a moment so inopportune as to look like a hold-up, but it has been met judiciously by the Chamber of Mines, which has replied that the cost of living in the Transvaal has increased to no such degree as that claimed, while, on the other hand, the market-value of the product of the mines, namely the gold, has not been and cannot be increased to the consumer. A rise of 20 to 25% in wages would augment the cost of production by 1 shilling, or 25 cents, per ton, so as to put nine mines on the ragged edge of solvency, and thus endanger the employment of 1670 white men. Hence the Chamber of Mines demurs to any hasty action and suggests an investigation by a committee of representative employers and employees under a chairman to be appointed by the Government. This is a reasonable and politic solution of a threatening difficulty.

The Mid-Year

For the first time the Secretary of the Interior has issued a mid-year review of business conditions as reflected by the mining industry. By calling upon the agents of the Geological Survey in the different mining centres, he has been enabled to issue a valuable summary of opinions. We publish the one emanating from Mr. Charles G. Yale here in San Francisco. It speaks for itself. Mining in California is awakening to renewed activity. In regard to the copper industry of the country, the period of restriction of output has ended, most of the large mines having now brought their output to normal capacity. Many of the smaller producers, which were compelled to shut-down a few months ago, have resumed work. Mr. B. S. Butler's report on the subject summarizes the position by saying: "The output of copper has probably nearly or quite reached the normal. Wages have been raised where reduction had taken place and the industry in general is in a highly prosperous condition." As to lead and zinc, Mr. C. E. Siebenthal reports that a marked revival in the mining of these metals has followed the rise in prices. "The present smelter capacity is scarcely equal to the demands upon it. This renders it imperative that as much spelter as possible be produced per retort, and puts a premium upon high-grade ores." He explains that this means a

55 to 60% zinc concentrate. The lack of smelter capacity has caused several old coal-fired plants to be restarted in Kansas and Missouri. The Joplin district especially is booming; also the Miami district of Oklahoma. Better quotations for lead are also helping the zinc mines, for most of them produce both metals. Lead itself has been kept quiet by the stock accumulated during a dull period, but much of this has now been sold. Mr. F. L. Hess reports upon antimony and speaks of the 'boom' in that metal. The demand for it and the British embargo on exports have caused the best brands to rise from 7 cents before the War to as much as 40 cents per pound. The Chinese output, on which this country largely depends, has been increased, but it does not suffice. The Chapman Smelting Company has resumed in San Francisco, and a new smelter has been erected near San Pedro, to work ore from mines near Ballarat, in California. From Alaska and Nevada also some antimony has come, but the fear of a drop in the price of the metal as soon as the War is over prevents search for new deposits, although, of course, if a mine containing high-grade ore were found it could be run profitably even at the normal price.

References are made in a report, also by Mr. F. L. Hess, to the erection of the tin smelter at Perth Amboy by the American Smelting & Refining Company, to treat Bolivian ores at the rate of 3000 to 5000 tons per annum. This should prove helpful in any effort to exploit the meagre tin resources of this continent. Tungsten and molybdenum are now in great demand, owing to the requirements of the steel industry. The first American molybdenum mine to be worked on any scale is that of the Primos Chemical Company near Empire, in Colorado, while tungsten is also being exploited at a number of mines in Boulder county, Colorado. The quicksilver industry is one concerning which we have had a good deal to say in these columns. Mr. H. D. McCaskey, confirming our statements, refers to the rise in price from $40 to $90 per flask, and mentions the cessation of shipments from Italy when that country went to war. He concludes that "the domestic mines are without serious competition and are in a position to profit while the War lasts." The demand for explosives is abnormal and the few producers of mercury in California, Nevada, and Texas "will find some difficulty" in supplying the market. Mining for gold and silver, says Mr. McCaskey, is in a normal condition. Any danger of a shortage of cyanide has disappeared, the domestic production of that necessary chemical having been increased "under the freedom from foreign competition." A lower price for silver, which has fallen from an average of 55 cents in 1914 to below 50 cents, is noteworthy. It remains only to quote the final remark of the Secretary of the Interior, Mr. Franklin K. Lane. He says: "The mining industry is basal in its relation to the general business of the nation and these generally optimistic reports from all parts of the country are significant and assuring to all who desire the industrial advancement of the United States."

Big Business

An honored correspondent writes to us expressing the opinion that the depressed condition of the mining profession has been produced by the consolidation of mining and metallurgical enterprises. He holds that whereas formerly a hundred men found occupation in a score of small operations, now, in these days of vast agglomerations of capital, one-tenth the number suffices. Economy, you say. No, says he. In one sense perhaps, namely, the cost of production, but as the millions that compose our population are forced into strictest economy through the contraction of employment, they have no money to spend, and hard times ensue. It was so before the War. The trouble, he insists, began with the large consolidations, which naturally threw thousands of men out of employment. What is the use, he asks, of reducing cost if at the same time people are deprived of the means wherewith to purchase? The only corrective, he suggests, is to go back to small operations. In the mining districts such a state of affairs can be brought about by showing small operators how to make their mines profitable. That, he concludes, is one of the functions of technical journalism, particularly of a paper like the Mining and Scientific Press, which is nearer the mines than any other on this continent.

That is an appeal to which we respond. It is one that will evoke the sympathy of most of our readers. But first let us consider the premises to the argument. Big consolidations stifle small operations and depress the vitality of the mining profession. That is the statement. Remembering the days when a million tons of ore was a visionary quantity and recalling a period when a $100,000 mine was a respectably large enterprise, we are able to make necessary comparisons. Then $5000 was a handsome salary for even the cleverest engineer, and many of those thus recompensed worked cheerfully in charge of relatively small mines, as against the few who now receive $5000 per month and supervise the operations of an enterprise that includes a dozen or twenty mines consolidated into one property. Yes, the picture of a dozen 40-stamp mills crushing ore from an equal number of mines is attractive as against a 100-stamp mill crushing five times as fast for a single consolidated property. But those 40-stamp mills were supplied with richer ore than the big fellow and the latter earns a small profit from stuff that his predecessors would have found unprofitable. Mere bigness is not attractive, but it must be confessed that the large-scale operation is often necessary to furnish an economic basis of production. The disseminated copper mines with their 2 to 2½% ore are making fortunes for their proprietors by exploiting lodes that were intelligently diregarded in an earlier period when such ore afforded no economic attraction even to a skillful and experienced engineer. It was the improvement in concentration practice, plus the devising of suitable methods of mining cheaply, that brought these deposits within the definition of 'ore.' Before that they possessed only an academic interest. The copper mines of Ely furnish a good example. For many years small mines working

restricted and uncertain bodies of high-grade ore existed precariously, with more failure than success. When a broad-gauge engineer realized the conditions and adapted his methods to them, by steam-shovel and concentrator, these unhappy ventures were joined into one superb undertaking, involving much capital and the building of a railroad, but developing into an enterprise of commanding merit. This story was repeated at Bingham, and elsewhere, notably in Arizona. No, we cannot glorify the past in an economic sense, much as we sympathize with the human extinction that follows in the wake of material aggrandizement. Yet we realize the advantage to the home community of smaller enterprises owned and operated domestically. We have an example in the Mother Lode mines. These are small, compared with the Modderfontein, the Homestake, or the Treadwell, but they go ahead year after year giving employment to a resident population and to a number of local engineers, with results highly advantageous to the state of California. Those connected with them prefer to operate themselves rather than sell out to capitalists on the outside. The pleasure of the work, and a confidence in their own ability to perform it, prevents them from considering the transfer of their property. At the same time the gold lodes are such as not to justify the belief that they can be exploited more profitably by mere enlargement of the scale of operations. The general result would please our correspondent. Here the big consolidation finds no foothold. Yet at Grass Valley the main portion of an old gold-mining district has passed under the control of two companies, which have absorbed the adjacent smaller companies that used to operate there. No reason exists for believing that the community has suffered thereby, for those smaller companies had come to the end of their tether in most cases before they were swallowed by their present successors. Here we come to one of the advantages of consolidation; stability of enterprise. By averaging good and ill luck over a large area of mineral territory the consolidation escapes the unproductive years that kill a small property. The element of risk is lessened.

And yet we feel some sympathy with our correspondent's argument even though the logic of facts tends to refute it. Indeed, we want more of the smaller enterprises, if only for the reason that from them are incubated the bigger ones. Men have not yet learned perhaps that to manage a small mine of your own is more interesting, and sometimes more profitable, than to hold a block of shares in a consolidation that puts you aside as a passenger, no longer a navigator. Many a man that was leading a happy life in the busy occupation of managing a mine, which he controlled, has exchanged that status for the idle possession of a shareholding that left him nothing to do except watch the tape. Each man must be his own philospher. From the community point of view the capable mine operator is more desirable than the same man when he has become a gambler on Wall Street; the one develops a natural resource, the other uses it as a counter in a game, which usually, like Bill Nye, "he does not understand." The conditions of which our correspondent complains should correct themselves. The small operator sold out when he got more by selling than by operating. Formerly there was more money made by selling than by buying mines. Now purchasers are more wary, they are better advised, and they decline to discount an unknown future too liberally. The time may come, indeed the consolidators complain that it has come, when mines cannot be bought advantageously. Then the small operator will refuse to do business with the consolidator, who has become so exacting, and will pursue the even tenor of his way, working his small mine cheerfully without the hankering to 'cash in.' In short, the incorrigible law of supply and demand will adjust the difficulty.

Australian Metal Trade

An official statement, prepared in the office of the Federal Attorney-General, gives some interesting statistics concerning the metal trade of Australia. The year 1913 is taken as typical. Of the lead produced at Broken Hill, 208,000 tons, just 50% was treated locally, the other half being exported, under the control of the 'Lead Convention.' Of the metallic lead exported, a large proportion goes to China. Of the zinc, 89% of the output (188,270 tons) was exported to a German group, consisting of the Metallgesellschaft, Aron Hirsch & Sohn, and Beer, Sondheimer & Co. Of the copper produced by the leading Australian mines, 95% was controlled by the German companies, notably Aron Hirsch & Sohn and Brandeis, Goldschmidt & Co. The Great Fitzroy and Chillagoe companies shipped their product to refineries in the United States, where the copper passed to the American Metal Co., which is associated with the Metallgesellschaft at Frankfurt. Taking the production of the principal base-metal mines of Australia, 80% is exported and controlled by German metal agents. So says this official report, prepared in connection with an inquiry arising out of the War. All we need say is that it furnishes a scathing comment on the lack of enterprise, first of the Australian and then of the British. Of course, the consumption of metal in Australia is, relatively to Europe, small; yet much of it is exported as raw material to return as a manufactured product. Not even sheet zinc was rolled until the War made it imperative. As regards the British position, it is a fact that Great Britain consumes an amount of zinc exactly equal to the Australian output and consumes twice as much lead as that derivable from the Broken Hill lead concentrate that passes her ports on its way to the Continental smelters; while as to copper, Great Britain uses 140,000 tons, or three times the Australian production. One cannot but admire the enterprise of the German ore-purchasing agencies, which have been able to make such a successful industrial invasion of a foreign mineral region. At the same time, viewing the matter in a broad way, it is undesirable that ore-producers anywhere should be under the thumb of cartels, conventions, or syndicates so concentrated as to be able to control not the output only but the market price of the metals.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more vaulable than casual compliment.

Speculation in Mines

The Editor:

Sir—It has never occurred to me that the question of speculation in mining enterprises turned in any way upon the factor of venture *per se*. If the nature of mining has made it attractive to questionable promoters, surely no discussion should be necessary to eliminate all such and to put absolutely aside the too numerous peddling schemes that wholly lack the element of good faith. The fact that such gentry have flourished in the United States, and have given some excuse for the sneering attitude of financial authorities toward mining has nothing to do with the soundness of mining as an industry. For some reason, not germane to the present subject, financial approval has been given most freely in this country to railroad securities; yet these have found a fairly rocky road to travel, with frequent reorganizations that, of necessity, have fallen most heavily upon those least able to protect themselves. Until the average shareholder in American corporations comes to realize that he must expect the treatment accorded to a sheep, if he insists upon playing the rôle of a sheep, the evils of which he complains will continue. There never has been, and, so long as human nature continues to be an imperfect thing, there never will be, evolved a system of jurisprudence that will remove the requirements of self-protection.

If mining does not hold the place it should in the ordinary layman's classification of the sources of wealth, it can only be due to ignorance, the ignorance traceable to a distinctly American habit of letting others do the thinking for the man in the street. Miles Standish and Caesar agreed in the saying that "if you want a thing well done, you must do it yourself and not leave it to others." As Americans we have largely refused to shoulder our financial and political duties, but have "left them to others." It would be quite unfair to accuse the American public of a lack of intelligence, but is quite true that as a whole that intelligence is not used as fully as it should be. All forms of business activity depend primarily upon the uninsurable business risk. The timid man who seeks to protect himself against every possible contingency of loss must be content with an extreme minimum of profit. Such men are never creators of anything, yet this is the type that condemns all mining as unduly venturesome when he happens to learn of some unwise or dishonest promotion coming to an inevitable end.

It has been suggested in the discussions of preceding contributors that if the financial managements of mining companies could raise money by assessment, when needed, it would go far to cure some of the present-day troubles. I am inclined to the opinion that in so far as this is a step toward more complete co-operation, it is good, but the principle should be carried further, if possible. I have always considered that the best and most satisfactory results in mining could be obtained through properly organized development companies, with a staff that would pride itself upon the number of properties it developed rather than upon those which it rejected.

Writing as a student of conditions and without the least desire to criticize without cause, I am inclined to think that engineers have developed an undue fear of failure; it has become almost impossible to get a recommendation that expenditure be made upon a property that cannot absolutely demonstrate its ability to re-pay at least all such outlay. The result is a deadlock, with development companies reporting, and apparently taking pride in the report, that large numbers of prospects in various stages of development have been 'turned down.' Rejections do not count, but prospects turned into mines do. The investor, with but the one string to his bow—a holding in a single company—is perhaps justified in his sense of discouragement, when the vein pinches out. If, however, the same capital is in the form of a holding in a development company, with adequate resources, a good staff, and some aggressive spirit, he can feel that one failure is of little moment.

It may be replied, with truth, that we have not enough of such organizations, or that those that do exist lack some of the qualifications requisite for successful operation. On the other hand, those organizations that have to some extent adopted this course and shown themselves capable have no lack of followers.

The moment a good organization comes into being and is ready to demonstrate to the public that the only risk which the shareholders will have to face will be that of legitimate mining, of finding and treating the ore at a profit, it will discover a public that will never complain of any failure made in good faith, but will remember and applaud every success, nor will it unreasonably expect that "every post shall be made a winning one." Inside options must be eliminated, and the work of excavation must be done on mining properties and not in the way of making ground-floors and sub-cellars. This completes the cycle: it is up to the investor to insist upon these conditions and not expect that others will serve him where he should serve himself.

When engineers are ready to say that they cannot expect to be infallible, that it should not be expected of them, and that such expectation compels them to take no chances and consequently get nowhere, but that in the long run they will be right often enough to show satisfactory profits for their financial sponsors, then mining will begin to have at its command the resources it deserves.

Gold Mining in Bolivia

The Editor:

Sir—The department of La Paz unquestionably contains the richest gold placers in Bolivia, and it is also regarded as being the richest in gold veins. Among its nine provinces, Inquisivi is supposed to be the richest. The western boundary of Inquisivi follows for a long distance the summit of the eastern Cordillera, descending toward the east and north. The province is exceedingly rugged, transversed by many mountain ranges and corresponding deep canyons, accessible only by trails. Although the Bolivian government, besides its extensive railroad system, is building good wagon-roads, and has now nearly 1000 miles constructed, Inquisivi has the smallest ratio of good roads, on account of the difficulty of establishing an easy grade. Inquisivi for a long time has had more road accidents recorded than all the other 51 provinces of Bolivia together.

The many tin mines in the Quimsa Cruz district were difficult of access; now there is a stage-road in operation from a station on the Bolivian state railroad in Sicasica, across the Quimsa Cruz pass, down into Inquisivi, with many branch-roads and trails to about 20 different tin mines.

According to the 'Monografia de la Industria Minera in Bolivia,' by Pedro Aniceto Blanco, published by the Bolivian government at La Paz in 1910, there is a group of three rich gold mines in Inquisivi. These are the Havara, the Sacambaya, and the Cutavito, established and operated for many years by the Jesuits with great results. Notwithstanding the long war of Independence, lasting from 1781 to 1825, the gold and silver mines made a good production, and it is supposed that these three mines also were in operation until 1825. Large sums of gold had accumulated, which the Jesuits could not take along with them, and on leaving, they buried it in the vicinity of the Sacambaya mine. In most cases a caretaker was left behind to look after the properties, as the Spaniards hoped to return eventually with a new army to re-conquer the country. Another rich gold mine, with a wonderful production, was the San Juan Bautista, also supposed to be in the mining district of Chuquircamiri, in this same province of Inquisivi.

About 1846, Jose Maria Dalence was directed by the President of Bolivia to explore the whole country and compile a list of all the mines and placers. For this purpose he was provided with a number of old maps. His report, published at Sucre (Chuquisaca) in 1851, is entitled 'Bosquejo Estadistica de Bolivia.' Dalence had also been charged to find these three mines and the buried treasure near the Sacambaya. But the whole landscape had been so much changed by the forests that had grown up that he could find none of them, nor the San Juan Bautista. Besides, the inhabitants had all departed, nor could he obtain any help, guides, or provisions.

P. A. Blanco has published, with his book, a map showing the position of the most important mines, but none of these four mines, nor even their respective districts, has been indicated. I have an assortment of maps bearing on Bolivia. On one of them the district of Havara in Inquisivi province is shown; there is also a village of that name. I would have no difficulty in finding the Havara district.

As to the authenticity of these three mines, I may mention that in 1546, at the Royal Villa at Potosi, a book of record was kept, giving the names and owners of all the gold and silver mines in Bolivia (then called Peru Alto), with the yearly production up to 1825, for the collection of the 'Royal Fifth,' to be sent yearly to the treasury of the king of Spain. These records have been transferred from Potosi to the Government archives at La Paz. It is known that every year a copy of these yearly records had been sent also to the Royal Treasury at Madrid, and that subsequently these records had been transferred to the Royal Library, so a Bolivian Commissioner with copies of the La Paz records was sent to Spain to compare his copies with the records preserved at the Royal Library at Madrid. The Commissioner received permission to do this and found that the records of La Paz agreed fully with the records of Madrid, and are, therefore, authentic. It is evident that there cannot be any question as to the existence of these three gold mines and the authenticity of their production figures.

On June 12, 1666, a great revolt of the Indians of Bolivia broke out, during which the San Juan Bautista mine was completely destroyed. The Spaniards had to flee. The Indians defaced the portals of the adits, destroyed the reduction works, all the dwellings, broke the aqueducts, and for years had guards stationed for miles around to prevent any Spaniard from coming near. Nature finally helped, for the tropical rains caused the chaparral and forest trees to obliterate the trails and the fields where the Indian women were forced to raise the corn to feed the mine-population, now departed to other parts of Bolivia. The destruction of the three mines in the Havara district followed 115 years later.

There would not be much difficulty in discovering the Havara, Sacambaya, and Cutavito mines by searching for the ruins of reduction works, dwellings, broken aqueducts, flumes, frequently hewn along the mountainsides from solid rock and leading to large cisterns, *quimbaletes* (rocking-stones for fine crushing of ore), and the accumulations of immense waste and tailing-dumps; all these objects would not be effaced in a thousand years. Much information can be collected from the natives and also from descendants of the early Spaniards. Many of these were engaged in farming and trading; not having taken part in the war, they had nothing to fear from the

Indians. In actual war-time, they absented themselves, but always returned to their homes. As a rule, these Spanish descendants kept up the family records, and by getting in touch with them much information from former times can be obtained.

The result of finding some of these gold mines would be the obtaining, from the Government, of a leasehold at the rate of 2 Bolivianos (80 cents) per hectare (2.47 acres) per 6 months. So long as this leasehold tax is paid, the company is in undisputed possession of the property. Wages are low, about 80 cents per day, the workman buying his own food. Bolivia is a member of the Postal Union and parcels can be sent to the United States, up to a weight of 10 lb., for 12c. per lb. There is also a large banking and commission firm with many branches in Bolivia and main offices in New York and San Francisco, that could attend to the shipment of bullion. All iron-work and machinery is admitted free of import for mines, concentrators, mills, and smelters. The mining laws are good and the United States government maintains a legation at La Paz.

Berkeley, California, June 12. G. W. Wepfer.

Assay of Ore Containing Metallics

The Editor:

Sir—In his letter, 'Assay of Ore Containing Metallics,' in the issue of June 5, W. E. Cahill describes a modification of the usual method of assaying ore containing metallics. Mr. Cahill states that by adding pulp to bring the total up to one-half assay-ton it is not necessary to weigh the metallics in order to make the calculation for its equivalent weight in pulp, as that is automatically done. While this is not apparent from his discussion, the following mathematical computation shows it to be true.

In the usual method, assaying the pulp, finding the total gold in the pulp, finding the amount of gold in the metallics, and then distributing the total gold over the whole sample, if

P_1 = the weight of pulp in grams,

P_2 = milligrams of gold per assay-ton of pulp,

M_1 = the weight of the metallics in grams,

M_2 = milligrams of gold in metallics,

T_1 = the weight of the sample in grams = $(P_1 + M_1)$,

then the amount of gold in ounces per ton (of 2000 lb.) of sample is

$$\frac{(P_1)(P_2)}{T_1} \qquad \frac{(29.166)(M_2)}{T_1}$$

This corresponds to the formula on page 259 of Furman's 'A Manual of Practical Assaying.' Transform this into Mr. Cahill's method by separating the expression into two terms having a common denominator. The first term $(P_1)(P_2)/T_1$ can be written $P_2 - (1 - P_1/T_1)P_2$ or $P_2 - (T_1 - P_1)(P_2)/T_1$ or $(A + B)_2 - (M_1)(A + B)_2/T_1$. The second term of the expression $(M_2)(29.166)/T_1$ represents the amount of gold in the metallics divided by the assay-tons in the sample. In terms of Mr. Cahill's method this can be written $[G_2 - (\frac{1}{2}$ A.T. of pulp − weight of metallics) $(A + B)_2/29.166]$ 29.166 T_1 (G_2 being total gold from pulp plus metallics to $\frac{1}{2}$ A. T.; the expression in parentheses being the actual amount of pulp $(A + B)_2$ 29.166 the milligrams of gold per gram of pulp) or,

$$\left[G_2 - \frac{(29.166)}{2} \cdot \frac{(A + B)_2}{29.166} + \frac{M_1(A + B)_2}{29.166}\right] \frac{29.166}{T_1}$$

or,

$$\left[G_2 - \frac{(A + B)_2}{2}\right] \frac{29.166}{T_1} + \frac{M_1(A + B)_2}{T_1}$$

this last portion of the second term is seen to cancel with the second part of the first term, this being the automatic adjustment of Mr. Cahill's method. Collecting terms the formula is,

$$(A + B)_2 + \left[G_2 - \frac{(A + B)_2}{2}\right] \frac{29.166}{T_1}.$$

Substituting figures given, then $(4.48 + 4.52) + [94.50 - (4.48 + 4.52)/2]$ 29.166 292 or $9 + (90)(29.166)$ 292 = 17.989, or practically 18 oz. per ton.

Mr. Cahill's method affords considerable advantage over the usual method both in procedure and computation.

Reno, Nevada, June 15. J. J. Bristol.

The Mechanical Work of Crushing

The Editor:

Sir—In the article by H. C. Kenney, in your issue of April 10, there seems to be a serious lack of 'precision of thought.' On page 573 the author takes the theoretical case of a knife cutting a soft cube. I fail to see what this has to do with crushing ore—we *crush* ore, we don't *cut* it. All fracture is finally caused by tensile strength, but the work required to produce the necessary tension varies with the manner in which the force is applied. Thus in the case of compression (or shearing), the deformation (as Mr. Kenney states), is proportional to the dimension of the test-piece in the direction of the application of the force, and the work is proportional to this deformation.

In the case of cutting, the knife stretches the surface layer till it breaks. The work is measured by the distance the knife has to travel before rupture occurs, and this is quite independent of the dimensions of the test-piece. Thus the work required in each case is not necessarily the same. To say that any mechanical means can "sever the molecular bonds without causing distortion," is to deny that "strain is proportional to stress." Otherwise it means that an infinitely sharp knife can cut materials without the exercise of any pressure on the blade; in other words, that it can cut without doing any work. The rest of page 573 is based on this fallacy. Confusion again appears in the attempt to differentiate between "work of compression" and "work of rupture." The work is done in compressing the body up to the point of rupture. When this is reached an infinitesimal increase causes rupture, and no more work is done. The potential energy of compression changes to heat, to surface tension of the new faces, and to electrical forms of energy.

Technical Reminiscences

By E. GYBBON SPILSBURY

When asked by the Editor to contribute some reminiscences of my technical experience, I could not but wonder how much age had to do with this request. Knowing how careful the said Editor is in the use of his own experience, I felt that nothing short of real ancient history was expected under the title of "reminiscences," and, therefore, to reach back that far I shall have to begin at the date of his own birth.*

At that time I was representing an important German zinc and lead mining company, on the island of Sardinia, investigating the zinc resources of that island. Captain Thomas Rickard and his brother Richard reached the island about the same time in the interests of the mining firm of John Taylor & Sons, of London. As we were the pioneers in the work of developing the immense calamine deposits only then just beginning to be known and appreciated, and also being practically the only English-speaking engineers in the country, we were naturally thrown much together, and although our interests were somewhat opposed, personally we became quite intimate, and I well remember the invitation I received at my camp one day to come down to the town of Iglesias and dine with the Rickards to celebrate the advent of "young Tom" on this mundane sphere, the news of which event had just been received from Spezzia, where the family then was. Needless to say, I went and we did!

This early pioneer work in Sardinia was most interesting and instructive. In the first place, the island was almost as much a *terra incognita* as our own West a century ago. The only towns were along the coast and there were only two roads on which wheeled vehicles could be drawn; the one connecting Cagliari in the south with Sassari in the north, and the other connecting Cagliari with Iglesias in the south-west. All communication outside these two roads was by trail. And yet the civilization of Sardinia was one of the oldest in the world. Every district where mining became later developed had numerous workings of the ancients. The Phœnicians, the Egyptians, and later the Carthaginians and Romans had all left their marks, in old excavations, dumps, slag-piles, and more especially in the tombs, cut out of solid rock.

In those days, every old mine yielded no end of specimens of bronze tools and lamps, stone picks, and hammers made either of jasper or obsidian. The tombs yielded pottery of all sorts and scarabs of malachite and turquoise. The old slag-piles yielded lead slabs and pigs, with the Government seal and dates cast in them. Altogether it was a paradise for the archæologist, if not for the miner.

Mining for the first few years was conducted under difficulties, owing first to the unhealthfulness of the country during the summer months and secondly to lack of native labor. The prevalence of malarial fevers and cholera necessitated the cessation of all operations for the three summer months each year. All foreigners had to leave, even the imported labor from Piedmont could not stand the conditions. So that our calculations had to be based on a nine months' campaign. The natives themselves were more or less immune, but, owing to the peculiar tribal or village system under which they lived, they could not be induced to mingle with others not of their village and work in harmony with them.

The extent to which this segregation obtained through the island was really remarkable. The cause was attributed to lack of intercourse, due to the poor means of communication, but it was primarily attributable to the diverse origin of the tribes. Probably no region of equal area in any country contained so many different customs, costumes, and languages as existed in Sardinia at that time. General La Marmora, who wrote a history of the peoples of Sardinia, gives, I believe, 11 distinct languages as being spoken. One interesting case he mentions, and I verified it personally, was that of a community in the province of Sassari on the north-western coast, where the classic Latin is still the common language of the people. The costumes were varied and picturesque, and each village had its own. In the south the type was Moorish and the *bournous* was still worn. In some places the costumes resembled somewhat those of the Basques, but with more vivid colors.

In those days the north and eastern parts of the island were dangerous for foreigners as well as difficult of access. The tribes occupying this mountainous district did not recognize the Italian government and were generally classed as bandits. Many of them were so, being escaped convicts from the penal establishment near Cagliari. They had a government of their own, which, while not recognized by the Italian authorities, was winked at and not interfered with, except when some raid or other on the villagers of the lower country required a counter punitive raid by the *carabinieras* of the Italian army. As a rule these so-called bandits were a pretty decent set of fellows, as long as they received fair treatment.

There was one episode that I recall with much pleasure; it happened during the second year of my stay. I was camped near the village of Villa Cèdro, opening up a new mine, when one evening just when I was about to retire I heard a disturbance outside and the clatter of a number of horses. Thinking at first that I was about to be raided by the bandits, who were reported in the neighborhood, I called the two foremen who were in the house with me and getting our guns we started to see what the

*The Editor appreciates the joke and will take pleasure in signing the card.

trouble was. Opening the door, I saw a small cavalcade, some of which consisted of gendarmes, coming up to the house. The leader, a very tall and slim young gentleman dressed in full hunting costume, got off his horse and coming up the steps addressed me by name. Stating that he had a letter of introduction for me, he asked if he and a friend could stay the night. Of course, I told him he was welcome, if he could put up with our rough accommodations. He called to his friend and then entered the living-room, where there was a light. I thought I had never seen a taller or lankier fellow, but withal a most pleasant face. After getting rid of some of his wraps, he handed me a letter from one of the directors of our company asking me to do all that was possible to make the stay of the bearer as pleasant as I could, as he was a friend of theirs, being the Duke of Brabant, afterward Leopold the Second, King of the Belgians.

The Duke had come to Sardinia on a *mouflon* [mountain sheep] hunt, and as my camp was situated in the best mouflon country he stayed with me for several days. He never forgot the experience of that trip and years afterward when he had succeeded his father, I always received a hearty welcome whenever I met him either in Bruxelles or more often, in the latter years of his life, in Paris. A curious coincidence was that the last time I met him, about a year before his death, he was again in the Mediterranean, but this time at Messina on the island of Sicily.

At the time of my first visit to the island of Sardinia, the chief, if not the entire, metal products were lead and silver. These had been mined as far back as the time of the Phœnicians, and the extensive old workings as well as the slag-dumps showed the extent to which the business had been carried on.

The decline in the industry dated evidently back to the period following the dismembering of the Roman empire, as no relics of a subsequent date have been found, so far as I remember. In 1864 there were only two large producing mines operating on the island. These were the Montevecchio lead and silver mines in the central part of the island, and the Monteponi mines in the province of Iglesias in the south-western part. Both of these mines were treating galena as well as oxidized ores, while nearly all the old mines had worked only on the carbonate ores. About the year 1863 a new mining excitement seems to have been started, mostly by French prospectors, and concessions were obtained and capitalized on the ancient mines. This resulted in disappointments, as the mineral that was supposed to be cerussite turned out to be chiefly calamine.† This discovery, however, called the attention of the European zinc-smelters to these deposits as a source of supply, and in a few years Sardinia became the principal zinc-ore producer of Europe.

It was not long before the Monteponi Mining Co. began concentrating its lead ores more efficiently, saving the zinc silicate for further concentration and shipment. It was in carrying out this work that the presence of anglesite in large quantities in the lead veins was discovered, and a source of trouble in the smelting of lead carbonates was thus eliminated. Probably no other mine has produced as much natural lead sulphate as Monteponi, not only as cabinet specimens, but actually in bulk.

It may be of interest to note that the identification of the amorphous calamine of Sardinia was made possible by the discovery, a few years previous, of a similar cherty-looking mineral that occurred in a banded form in the Breinigerberg lead and zinc mine near Stolberg, in Rhenish Prussia. In the hand-jigging methods of concentration of those days, this material, which was much harder than the ordinary calamine, or zinc carbonate, was easily picked out and had been discarded as worthless until somebody out of curiosity analyzed it and found it contained as much zinc as the best carbonate ore.

The reduction of these silicate of zinc ores, however, offered no end of difficulties because the calcining, which by driving off the carbonic acid in the carbonate ores left that material in a porous condition and easily permeated by the reducing gases, had no effect on the silicates.

The principal markets for these zinc ores were in Belgium and Rhenish Prussia. Nearly all the zinc-smelters of these districts were either actually engaged in mining themselves, or were represented by buyers on the island of San Pietro at Carlo-Forte, which was the principal shipping port for all the ores mined on the western side of the island. The mines shipped their ores by lighter to Carlo-Forte and those not consigned direct were sampled there and sold at public auction once a week.

The method of shipping across the Straits was crude in the extreme. The ore was delivered by bullock-carts on the beach at Fontenamare, and when a shipment was ready it was loaded in baskets and carried out to the flat boats or lighters on the backs of men and women, who went into the water up to their shoulders before reaching the boats. The unloading at Carlo-Forte was done in the same manner. It was not till some years later that any mechanical loading devices were installed.

I wonder how many mining engineers of the present day can call to mind the changes and advances in the practice of mining which have taken place in the last half-century? Practically every appliance, beyond the pick and shovel, hand-hammer and drill, has been introduced during that short period. When I first started my practical course in underground work we knew none of the aids now considered requisite to work economically. We had no machine-drills to save the physical labor of hand-work. Dynamite or its precursor nitroglycerine had not yet been invented; fuse was still unknown; even steel was more or less of a luxury and our hand-drills were still made of iron with steel bits welded onto them. The mushrooming of the head of the drill under the hammer-blows was a constant source of trouble and injury to the hands of the miners. The only explosive known was the large-grained black powder.

†Here used for the carbonate. As our readers are aware, that is the European usage.—Editor.

It seems strange now to remember that part of the curriculum in the mining colleges consisted in instruction in how to prepare the cartridges of brown paper for the charge; how to waterproof them by soaking in tallow; how to prepare the long rye-straws for fuse and fill them with fine sporting powder; and how to prepare the slow fuse for ignition by soaking cotton wicking in molten sulphur and cutting it up into the proper lengths.

It seems hardly credible today, and yet it is a fact, that the contract price for driving or stoping ground was influenced by the condition of the rye crop. In seasons of drought the height of the rye was much curtailed, and the length of the straw between joints would be so short that the time occupied in jointing and filling the straws greatly lessened the driving capacity of the miners, and hence increased the cost per foot or per ton. Single-hand drilling was the general practice except in extraordinary hard rock, when double 'jacks' were used. The straw primers naturally limited the possible depth of a hole, and three feet was considered a good average. It was the invention of the tape fuse that brought the double-hand hammer into vogue, and made deeper drilling possible.

Lately there has arisen a good deal of discussion regarding the meaning of the terms 'tamping' and 'stemming,' the idea being that one designates the material used, and the other the method of introducing it into place. These terms, however, reach back to the straw-fuse period. 'Tamping,' from the French *tampon*, a plug, originally meant the material used for the plug, but was also generally used to express the action of inserting the plug. 'Stemming,' on the contrary, referred originally to a different part of the same operation, namely, the insertion of the copper stem or needle around which the tamping was driven so tight that when the needle was withdrawn it left a clear tube from the mouth of the drill-hole through which the straw fuse could be introduced and pushed home into the charge. The tamping-bar, which was copper-faced, was nearly of the same diameter as the hole, but along one side it had a groove in which the stem or needle would lie. What was known as 'stemming' in those days was the method of jarring the needle as the tamping progressed so as to make sure of its safe withdrawal without disturbing the completed tamping. This withdrawal was effected by passing a drill through the eye of the stem and using one end as a fulcrum, tapping the other end with a hammer until the needle was loosened sufficiently to be withdrawn by hand.

No detonating caps were used except in very wet holes. The end joint of the straw was split with a sharp knife before insertion, and the blow-out from the sporting powder was sufficient for the ignition of the charge. These straw fuses were very rapid and it was necessary to ignite them by a slow-burning sulphur wick. The choice of tamping material was not left to the miners, but was provided by the company, and the use of any other material rendered the miner liable to fine. As a rule the first plug next to the cartridge was of burnt clay, while the rest of the tamping was coarsely ground limestone.

A miner's equipment in those days consisted of a long tin tube to carry the lengths of straw for fuse and a sheath on the outside for the copper needle; this was the miner's own property; also attached to the main tube were smaller tubes or boxes containing the sulphur wicks, the sporting-powder priming, and the paper for cartridges; he also carried a flask of blasting-powder, and another smaller flask for oil, besides a water-flask, generally filled with coffee. All of these receptacles were inspected by the foreman as the men went on shift. In the German mines the men all assembled in the foreman's office for prayers before beginning their shift.

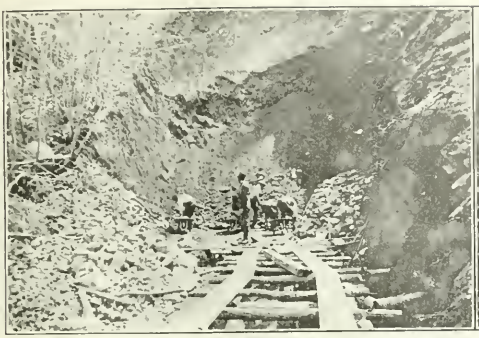
Except under special conditions no men were allowed to be raised or lowered by the hoisting-engine, the ladders being used both for entry and exit. In some of the very deep mines, however, a special man-engine or *fahrkunst* was used, greatly lessening the time spent in climbing ladders.

Mining Claims in National Forests

In many mining districts in the West there is some opposition to the practice of the Government in having claims within the National Forests inspected before the issuance of patent. Many mining men feel that they are entitled to patent to mining claims, particularly in established mining districts, even if they have not made mineral discoveries on the individual claims.

Congress has set aside a part of the public domain for a specific purpose—for the growing of timber, and the protection of the watersheds. The fact that any ground has thus been withdrawn is *prima facie* evidence that it has a definite value for the uses prescribed by Congress. Is it unreasonable for the Government to require mining claimants to comply with the Federal law before giving them absolute title to a part of its domain which has been designated by Congress as having a presumptive value for the purposes for which it has been reserved?

A prospector or miner is in no way disturbed by Government agents in the enjoyment of his rights within National Forests. No examination is made of any ground located for mining purposes unless, as stated, it interferes with the administration of the Forest. A claim may interfere with the administration of the Forest when it conflicts with areas leased to individuals under what is known as a Special Use Permit; when it is included within a tract from which the Government has sold, or contemplates selling, the timber; or where the claim is so located as to control rights of way over which it is necessary to transport forest products. At the present time, in some parts of the country, the timber business within the National Forests is seriously interfered with by unscrupulous locators of ground under the mining laws. In all such cases, the Government has a direct interest at stake, and an examination of the interfering mining claims is made to determine their validity.—E. D. Gardner in Trans. A. I. M. E.



EXCAVATING FOR THE DAM.

THE DAM ITSELF.

A Novel Debris-Dam

By LEROY A. PALMER

Gold was accidentally discovered in California in 1848. In 1849 fully 100,000 miners were washing the gravel in the streams and gulches of the Sierras. The pan was shortly followed by the rocker, brought from Georgia, then came the 'long tom' and the 'sluice-box.' With the sluices came the demand for some means of moving the gravel in larger quantities than before and an ingenious Yankee conceived the idea of directing a stream of water against the bank, using a rawhide hose with a cow's horn for a nozzle. This method was so effective that it was generally adopted and the crude apparatus soon developed into the steel penstock and the hydraulic giant of a later day.

The progress of hydraulic mining brought forth a problem that resulted in much bitter feeling and long continued litigation between the different interests involved. The first comers were essentially miners and sought gold regardless of the consequences that might attend their search. But the agricultural possibilities of the country were too great to be long overlooked, therefore many of the newcomers turned to this industry and much land was put to the raising of crops, the valleys watered by the largest rivers, the Sacramento and the San Joaquin, being the first and most thickly settled.

These streams flow with gentle grades through wide valleys covered with the flood-plain deposits of earlier periods. Consequently the spring freshets result in floods that spread over a considerable territory unless controlled by levees. Calculations have been made of the rate of erosion of various rivers. Using the figures of the Po, in Italy, where conditions approach most nearly those of the Sacramento, it has been estimated that the sediment carried by the latter which is derived from the natural erosion of its own channel and its tributaries varies from 5,600,000 to 43,000,000 cu. yd. per year. The problem was serious enough in itself without adding to this amount the vast quantities of debris resulting from the placer operations, which in many cases had grown to enormous size and had involved large amounts of money in permanent works.

The accompanying photograph shows part of the pit of the Malakoff mine at North Bloomfield, in Nevada county, the largest placer mine of all time and one from which some of the most valuable data on hydraulic mining have been obtained. One can get some idea of the debris of this one mine by realizing that its banks reached a maximum height of 265 ft., water was used under a head of 800 ft., a static pressure of 347.2 lb. per square inch, and directed against the banks through nozzles with diameters up to 8 inches. In 1877 the Malakoff used 595,000 miner's 24-hour inches and moved 2,993,930 cu. yd. of gravel. From 1870 to 1877 inclusive it moved 11,-021,630 cu. yd. of gravel.

Various figures have been given as to the duty of water in hydraulic mining, all of which vary widely, the chief factors being the character of the material and the size and grade of the sluices. At the Malakoff it varied from 18 to 21 cu. yd. of water for each yard of gravel. Harts* places the average duty at the mines on the Sacramento watershed at three cubic yards per miner's 24-hour inch, equal to 26.66 cu. yd. water per yard of gravel moved. These figures are quoted to give some idea of the immense amounts of debris washed from the watersheds of the rivers mentioned. It must be remembered that when hydraulic mining was in its prime practically the entire flow of the mountain streams was put to this use.

The State Engineer of California estimated that in 1880 53,400,000 cu. yd. of sediment and gravel found its way into the Sacramento basin. 18,100,000 cu. yd., of which 4,900,000 cu. yd. was the result of natural erosion,

*For most of the data concerning erosion and the debris deposited I am indebted to 'Control of Hydraulic Mining in California by the Federal Government' by W. W. Harts, Trans. Am. Soc. C. E., Vol. 57.

was brought down in suspension; of this 2,100,000 cu. yd. settled in the overflowed basins and 16,000,000 cu. yd. was deposited along the channel or carried into the bays of Suisun and San Francisco. From 1849 to 1880 the low-water plane of the Sacramento was raised 7½ ft., tides at the city of Sacramento almost disappeared, navigation was seriously impeded, and it was estimated that this stream contained 108,000,000 cu. yd. of placer debris.

Conditions on the San Joaquin river were similar, but it is probable that the Yuba, to which the largest operations including the Malakoff, were tributary, was the greatest sufferer. It was estimated that the Lower Yuba contained 333,000,000 cu. yd. of debris and the low-water plane at Marysville was raised 15 ft., making necessary the construction of an extensive system of levees to protect adjacent lands from inundation.

Obviously such a condition was intolerable to the agriculturists, whose lands were frequently overflowed and covered with fine tailing, and to those who had invested money in river-transportation enterprises. Various legal actions were started. After some years of litigation the year 1880 found hydraulic mining on the watersheds of the Sacramento and San Joaquin rivers practically stopped by injunctions obtained in the local and Federal courts.

At this point the matter was made the subject of investigation by Congress, and this investigation was carried on for eight years, from 1880 to 1888, finally resulting in 1893 in the passage of the Caminetti Act. This Act was ostensibly designed to protect the navigable rivers, but its provisions were such that it also has the effect of protecting the agricultural lands, as only those mines were allowed to operate that could do so without discharging their debris into the navigable streams. At first thought this might appear to be an assumption by Congress of authority over State affairs, for the trouble was confined to two river-basins in the state of California, but it is based on the constitutional authority of Congress to exercise jurisdiction over navigable rivers and interstate commerce. The validity of the Act has not been questioned; in fact, the miners welcomed any move that might permit even a few of them to operate.

The Act created the California Debris Commission, a Federal board of three members from the Engineer Corps of the U. S. Army, with authority to pass on all schemes for the impounding or controlling of debris from hydraulic mining operations with power to stop any that do not meet with its approval. Thus the effect of the Act is to permit such mines to operate as will install works adequate to control their tailing and prevent it from reaching the navigable streams of the valleys. The authority of the Commission is limited to the watersheds of the Sacramento and San Joaquin rivers, and its duties also include investigations and formulation of plans to improve the navigability of these streams in their lower reaches.

The Commission has worked with a broad-minded spirit, the result being that many hydraulic mines have been able to resume operations, while there has been a gradual improvement in the condition of the lower river-channels. The choice of a dam is wholly within the discretion of the operator, the only conditions being that it shall be efficient and safe. Many types have been used, notably stone, earth, brush and rock, and log cribbed with rock-filling. Some concrete dams have been built but in general they are too expensive for this purpose, so that the log cribbed with rock-fill is probably the most common. A debris dam, however, must combine efficiency and safety with economy. Most hydraulic mining is conducted on a narrow margin of profit and it has been found too often that the dam designed to meet the requirements of the Debris Commission added so much to the expense of operations as to make it unprofitable. For this reason the dam now under construction to impound the tailing of the Omega mine in Nevada county is of interest, as it has met the requirements of the Commission and has been constructed at a very small expense per yard of gravel hydraulicked.

The Omega hydraulic mine is situated on the channel of the Tertiary Yuba river about 3½ miles above Washington, California, an old settlement dating back to the very earliest days of the great stampede. It is perhaps fitting that the dam to be described, the first of its kind, should be built within a short distance of the spot where the clever Yankee first turned his water through the rawhide hose with its cow's horn nozzle.

The tailing from the Omega mine discharges into Scotchman creek. The first dam was built about 2½ miles below the mine and about a quarter of a mile above the South Fork of the Yuba river at a point where the creek cuts a narrow channel through the slate that forms a part of the Blue Canyon member of the Calaveras formation. This dam is made of concrete, 23 ft. long at the bottom, 55 ft. long at the top, 15 ft. thick on top with a down-stream face 45 ft. high. The reservoir formed thereby was of small capacity, so that it was soon filled, and as the length increased rapidly with the height the economic limit of such a dam was soon reached.

After a period of idleness the mine resumed operations and construction was commenced of what, for lack of a better name, may be called a 'basket' dam. The old concrete dam was used for the toe of the new dam and the tailing back of it was excavated to a depth of two feet. In the excavation, two tiers of baskets were laid butting against the old dam. The basket dam was designed by J. M. Howells, of San Francisco, who conceived the idea from the Japanese *jakago*, a levee facing of loose rock restrained by bamboos so constructed that if the facing is undermined by the current the rocks settle of themselves and cover the eroded spot.

Construction of the basket dam proceeded as follows: The baskets were made of ordinary poultry-netting of 14-gauge galvanized wire and 6-ft. widths. For a reason to be mentioned later the length of the baskets varies, eight feet being the average at the time these notes were made. Such a basket is made by cutting eight feet of poultry-netting and folding it over so as to bring the two bound

edges together on top and then wiring the meshes of the netting together on the ends. This can perhaps best be understood by folding a piece of paper as described. The result is a wire container that may be described as pillow-shaped with a seam opening lengthwise along the top and of such dimensions that when filled it will measure 8 by 2 by 1 feet.

In building the dam a two-inch plank is set on edge two feet from the bank, or from the last basket laid, and held in place by driving iron pins alongside. One of the empty baskets is set in the two-foot space thus formed and filled with small boulders, not larger than a man's head, with sand and gravel sprinkled into the interstices. The open edges of the netting are then brought together by means of a curved piece of strap-iron with a sharply curved hook on the end and held while they are tied together with wire. The down-stream ends of the baskets are lined to a wire stretched taut along the line to which they are to be built and the tops are brought to level with a straight-edge. A spillway 20 ft. long and 1 ft. deep is carried at one end of the dam. Each row of baskets is started with its down-stream face one-half its length back from the corresponding face of the basket on which it rests. Thus if 8-ft. baskets are used they will lap 4 ft. As the baskets are laid, gravel is filled behind them for 10 ft. so that the top width of the dam is 10 ft. *plus* the length of the basket, or an average at the Omega dam of 18 feet. The concrete dam was built at a point where the creek makes a sharp bend almost at a right angle, so that in carrying this dam up it has been necessary to curve it to conform with this bend, which gives it the fan shape shown in the photograph. On this account the length of the baskets has been varied, causing a corresponding variation of the slope of the down-stream face. At the time these notes were made the dam was 150 ft. long, including the spillway, and 35 ft. high, with a slope on the inner side of 2 : 1 and on the outer side of 6 : 1. The cross-section illustrates the average as it is at present, a 4 :1 slope using 8-ft. baskets. When the dam reaches a point on the stream where it is no longer necessary to carry the fan shape, 6-ft. baskets will be used with a lap of four feet giving a down-stream slope of two to one.

Conditions prevailing at the Omega site were not favorable to the lowest cost of operation. The ideal condition would be one that would allow of backfilling with a hydraulic giant, but this was not possible. Dragline excavators were tried, but it was found that under present conditions they are not feasible. They can be operated in another season. It was therefore found necessary to excavate with pick and shovel and move the dirt by wheeling. Fortunately there is plenty of gravel at each end of the dam, so that even with this method the cost is not excessive.

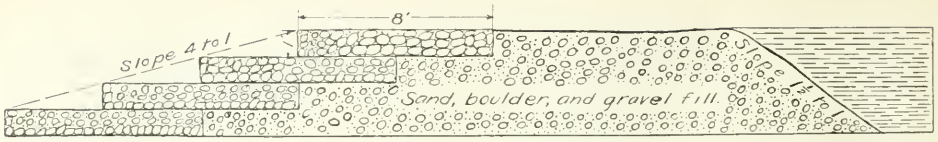
When the mine is discharging 1000 cu. yd. of tailing per day, the debris can be controlled by 2 men laying baskets and 4 men shoveling and wheeling. If wages are $3 per day, with a foreman at $4, this would bring the labor cost to $22 per day. This is the only expense except for poultry-netting and wear of the tools, which amounts to not over $5 per day, so that under present conditions the total cost is approximately 2.7c. per yard of gravel hydraulicked. However, as the height of the dam is increased the area of the pond increases rapidly in both length and breadth out of proportion to the increase necessary in the length of the dam as it is raised. For this reason it is expected that in another season the same amount of work and material now necessary to control 1000 cu. yd. of tailing will then impound approximately 4000 cu. yd., thus bringing the cost per yard of gravel hydraulicked to about 0.7 cent.

THE MALAKOFF GOLD-GRAVEL MINE.

The above crew can lay and back-fill 20 baskets per day. One basket (average at present) is 8 by 2 by 1 ft., so that the basket-work amounts to 320 cu. ft. per day. Back of the basket-work is 10 ft. of back-fill, 6 ft. of which is on the earth already filled in and thus only one foot deep while four feet must go down to the bottom of the pond, about 6 ft. on a 1½:1 slope, making a total for the 40 ft. of dam laid in a day of 1520 cu. ft. or 56.3 cu. yd. at a cost of 48c. per yard.

One of the regulations of the Debris Commission provides that the water in the pond must have a depth of at least 3 ft. below the level of the spillway at a point 150 ft. upstream from the dam. This regulation is wholly within the discretion of the Commission and may be altered one way or the other, as justified by the magnitude of the operations of the mine. It has been found that when it is met a depth of six feet of water is obtained at the dam.

The basic principle of this dam is the relief of pressure rather than resistance to it. The most impervious part is the back-fill, the up-stream face of which is continually covered with a layer of very fine silt, 'slickens' as



CROSS-SECTION OF THE DAM.

the placer-miner calls it. This silt makes the dam practically water-tight, but such water as does seep through makes its passage into the back-fill and spreads out in the many tiny open spaces therein or perhaps finds it way to the baskets. These are purposely made porous, so that the water which reaches them does not have a chance to accumulate and gain a pressure such as might eventually cause a failure of the structure, but gradually seeps through without resistance and discharges from the face of the dam under no pressure at all.

The step nature of the structure is also designed to offer a protection against erosion from floods. It will be noticed that every point on the face is protected by the thickness of two baskets. If a flood pours over the crest of the dam it is broken into a series of cascades, each one with only a drop of one foot and falling on two feet of the rock-filled baskets, so that obviously the damage from such a source would be slight.

In the spring of 1915 the dam was subjected to a severe and unexpected test of this sort when an unusually heavy and long-protracted season of rain brought a sudden flood down Scotchman creek. This poured over the crest of the dam continuously for five weeks. The flood was so unexpected that several broken boulders with sharp edges were left by the workmen on the crest of the dam. These were carried down the face in the first rush of the water and cut the wires of two baskets allowing, some of the filling to be washed out. It was five weeks before this damage could be examined and it was then found that the baskets above had weighed the others down and closed the opening formed by the escape of the filling so that no more boulders could work out, the displacement being distributed gradually through the other baskets, leaving the dam perfectly safe. It is here that the principle of the *jakago* comes into play, as it will also in case of the natural settling that may be expected of such a structure. But it is evident that it is impossible for any boulder of a size sufficient to injure the face of the dam to pass down the stream and through the several hundred feet of still water in the pond to the dam itself by any flood, however great.

The designer of this dam states that it is not the intention to expect it to act as a spillway for flood-waters except as may be occasionally required while the mine is in operation, and the dam itself is under the close oversight of those engaged in its construction. The Debris Commission requires that all dams not made of concrete shall be so constructed with a permanent bedrock or concrete spillway as forever to divert the flood-waters in such a manner as to guarantee the continuous storage of the tailing. The spillway required is proportioned to the precipitation and the area of the watershed, with a large factor of safety. In the case of the Omega it will be cut through the slate bedrock and will have a capacity of 2000 sec. ft., a factor of safety of 10, as the drainage-area of Scotchman creek is small and it is not expected that its discharge will ever exceed 200 second-feet.

This will prevent any water from being carried over the dam, which has not been designed with the idea that it will act as a permanent spillway. However, there seems to be reason to believe that the dam would be satisfactory even if put to this test. At first thought it might seem that its usefulness would be limited by the life of the baskets, that when the wires rust the baskets will fail, and the structure gradually disintegrate. But on further consideration it is reasonable to suppose that the constant percolation of silt-laden water through this basket-work will have a tendency to cement the loose gravel and boulders. It has also been found that the water which comes down from the mine carries a considerable amount of iron oxide, one of the commonest of nature's cements, in solution. This iron oxide is deposited from the water and one can observe this process of cementing going on to a limited extent at present.

That this dam is performing the service for which it was designed is evident from the fact that not only the tailing from the mine but the natural sediment of the creek is impounded. The water discharged actually contains less sediment than it did when the mine was not operating and there was no dam. I am indebted to J. M. Howells, C. E., of San Francisco, designer of the dam, for assistance in collecting and preparing these notes.

A PLACER is an unconsolidated deposit accumulated by mechanical processes, carrying one or more minerals in commercial quantities. All placers are secondary deposits; that is, the material of which they are composed was originally derived by erosion of bedrock. Although it is undoubtedly true that under certain conditions nuggets of placer gold have been enlarged through chemical precipitation, yet this action is a negligible quantity in placers. Placers may be derived solely by rock weathering without water sorting, but more commonly are the result of water transportation, sorting, and deposition. Many of the richest placers are those formed by the erosion of older placers and the re-concentration of their gold.

COSTS at the Mt. Lyell copper mine, Tasmania, during the six months ended March 31, 1915, totaled $6.86 per ton of ore smelted. This included the mine, smelter, railway, office, and depreciation.

Questions on Milling Practice

By A. O. GATES

Suppose we pile up pieces of crushed rock as shown in Fig. 1 and then strike *A* a good stiff blow. What happens to the various pieces? Which is damaged the worst, the big fellow or the little fellows?

And if *A* did not break on the first blow but passed it on, as big fellows usually do, when would he get his, if the licking continued? And what would be happening

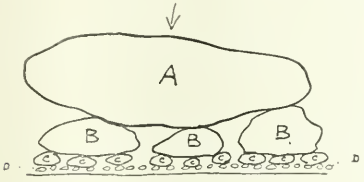


FIG. 1.

to *D* and *C* and *B*? This has nothing to do with the War.

Suppose in Fig. 2, *xy* represents the screen-analysis of the product from a crushing machine, and *xz* the product after an 'improvement' is made, either in the lining, the screen arrangement, the crushing medium, or in the type of mill; the ratio tonnage to horse-power being unchanged, has anything been gained? Do you get any better extraction from the + 60 mesh material than before? Whether it be washing-after-leaching, concentration, or flotation, do you get any better results out of the – 200 mesh material?

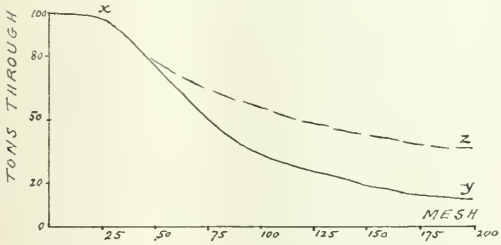

FIG. 2.

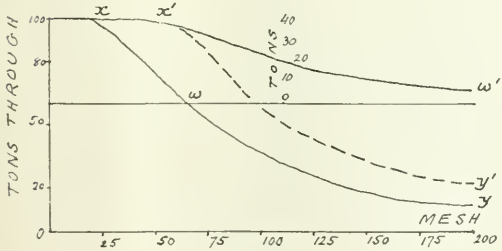

FIG. 3.

In your opinion would *xz* require more power?

Now suppose we again have the screen-analysis *xy* in Fig. 3, and we split it up into two lots *xw* and *wy*; we re-crush the coarser material *xw* to an analysis *x'w'*, which combined with *wy* gives the screen-analysis *x'y'*; how about the probable extraction on the 40 tons of coarser material corresponding to the + 60 mesh in Fig. 2?

Suppose the quantities of – 200 mesh at *z* in Fig. 2 and at *y'* in Fig. 3 are equal, which will probably have the larger quantity of – 1000 mesh? And which will offer the greater difficulty in concentration, flotation, or washing: the pulp with the greater percentage of – 1000 mesh, or the pulp with the less?

If the same horse-power per ton is required in producing *x'y'* in Fig. 3 as in producing *xz* in Fig. 2, which product is the more desirable metallurgically?

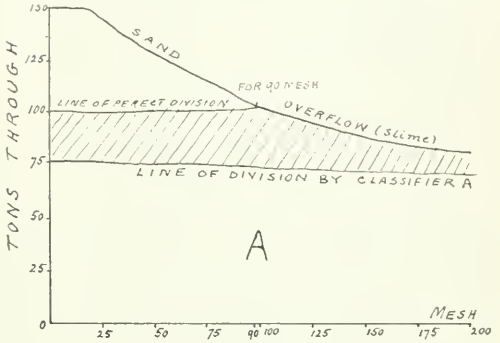

FIG. 4.

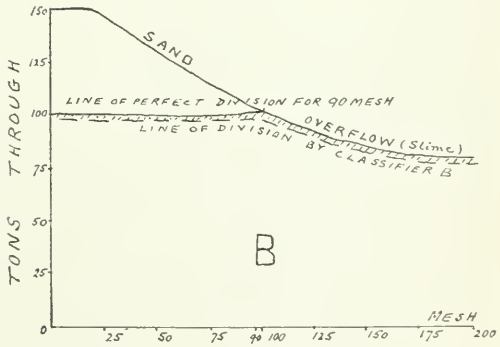

FIG. 5.

Is it good metallurgy to decrease the amount of – 1000 mesh and to increase the amount of – 100 mesh, that is, making the line of screen analysis steeper? If Rittinger be right, so that it takes ten times as much energy to produce – 1000 mesh material as it takes to produce an equal amount of – 100 mesh material, would the steepening of the screen-analysis line save any power?

One thing more and then I'll stop. Do screen-analyses, expressed in percentages placed side by side, give a clear conception of the difference in the operations? Take this example of two classifiers side by side, handling the

same tonnage of feed, moisture being around 5½ to 1.

		A		B	
	Feed.	Sand.	Overflow.	Sand.	Overflow.
Tons per 24 hr.	150	75	75	52	98
	%	%	%	%	%
+ 20	1	2	..	1.5	..
+ 40	13	27	..	37	..
+ 60	23	56	1	67	0.5
+ 100	35	69	5.5	92	2.5
+ 200	47	84	10	94	21
— 200	53	16	90	6	79

A has 90% of −200 mesh in the overflow while *B* has 79%.

But when you diagram it on the basis of a separation at 90-mesh there is a different look to it. The cross-sectional area, Fig. 4 and 5, represents the *surface* that got into the wrong place.

After you have answered all the questions you may go back to work.

Colloidal Chemistry

By CLIFFORD RICHARDSON

*Colloidal chemistry originated in the investigations of Graham in the sixties of the last century. It then lay dormant for forty years and has only recently been developed to an extent commensurate with the importance which it is now recognized as having. The original idea of Graham was that substances could be classified as crystalline and colloidal, with a sharp line of division between the two, according to whether or not they would, in solution, diffuse through an animal or semi-permeable membrane.

It is now recognized that colloids are merely a state of matter, one in a highly dispersed or subdivided condition. By appropriate means, in a suitable medium or phase with which the substance does not form a molecular solution, crystalline substances can be obtained in such a degree of subdivision or dispersion that they exist in a colloidal state, that is, they will remain suspended in a medium indefinitely. The chemistry of colloid matter then differs from the chemistry of matter in its ordinary form, merely by the degree of its subdivision or dispersion. In order to be dispersed in colloidal form a substance must exist in a system of at least two phases; an interior or disperse one which may be solid or liquid, and an exterior or continuous phase in which it is dispersed. The main characteristic of the disperse phase is its state of subdivision or degree of dispersion. Bancroft has characterized this as follows:†

"If we drop a stone into water, it sinks very rapidly; if we grind the stone into coarse particles these sink less rapidly; if we grind the stone into fine particles, these sink slowly; if we grind the stone into very fine particles we should expect them to sink very slowly, the rate being a function of the diameter of the particles. This is not the case, however. Very fine particles do not follow Stokes' equation and do not settle at all, because of the Brownian movements which are negligible for coarse particles. We, therefore, conclude that any substance can be brought into a state of colloidal solution provided we make the particles of that phase so small that the Brownian movements will keep the particles suspended, and provided we prevent agglomeration of the particles by a suitable surface film."

The Brownian motion to which Bancroft refers is one which can be discerned under an instrument known as the ultra-microscope which makes visible particles which are invisible in the ordinary instrument. It serves as a means of detecting matter in a colloid state which has been unavailable except within the last decade. The size of particles, when in a colloid state, is ordinarily as small or smaller than 0.0001 mm. in diameter, and in the case of some solids no larger than 0.000006 millimetre.

A realization of the enormous surface area possessed by disperse solid colloids of this size may be arrived at from the fact that if an amount of material represented by a cube, one side of which has a dimension of one centimetre, is reduced by decimal subdivision only to the coarsest colloidal size, a ten-thousandth of a millimetre in dimension, the number of cubes produced would be 10 to the 15th power, while the surface area would be increased to 60 square metres, or 100,000 times that of the original cube. The great increase in surface area of the finer material over that exhibited by the surface area of a single cube is at once made evident. Surface energy is demonstrated by the fact that if two plates of glass, which are ground perfectly parallel, be brought together with or without water, it is difficult to separate them, owing to the surface energy of the film of air or water which is imposed between them, energy far greater than can be attributed, as has been asserted, to the pressure of the atmosphere. This same phenomenon is exhibited in cementing together with bitumen the particles of a mineral aggregate of a sheet asphalt pavement, having a great surface area.

Adsorption is the power a solid or liquid surface has of holding thereon a thin film of solids, liquids or gases, an example of which is the film of air or water which is found under ordinary conditions on the surface of glass. Colloids possess this property to a high degree, owing to the large surface area they present. Adsorption is well illustrated by the manner in which a dye or coloring matter is removed from its solutions by a substance like charcoal or kaolin: this is known as selective adsorption.

[A good example of selective adsorption is the presence of iodine in seaweed. The iodine salts are selectively adsorbed, by the colloidal substance of the seaweed, from the sea-water, though the amount of iodine in sea-water is so small that it cannot be detected. This property of adsorption is of importance in many metallurgical operations, now that the practice has become general of grinding ores to an extremely fine state of subdivision in order to free the included mineral. With this fine grinding, the particles of ore tend to approach the colloid stage and if valuable chemicals are employed the tailing may carry away considerable quantities that cannot be recovered by any practicable amount of washing.]

Notes From South America

By MARK R. LAMB

Chuquicamata was formally started by his Excellency the President of Chile. The papers were full of favorable notices of the event and the company and Americans in general. One paper gave a particularly lucid statement of the advantages resulting in favor of Chile from this big enterprise, and expressed the wish that there were fifty such here. An analysis of the expenditures of the company showed clearly the amounts spent for labor and local supplies, and the article will go far to remove the last remaining traces of hard feeling against the concerns that are shipping such large quantities of mineral from the country.

After a shut-down of several months, the Guayacan smelter is to start again on a very moderate scale, shipping matte as heretofore, but in much smaller quantity. A small company is being formed to supply funds for starting, and it is expected that it will be possible to make more than expenses from the start.

The Calama company is in better financial condition than for many years. The mines are shipping a good quantity of sorted ore, and the little old smelter at Calama is making several tons of bar copper per month. The company is capitalized at $800,000, so that the dividends will be spread out rather thin. With present prices of copper, the management is making every effort to increase production.

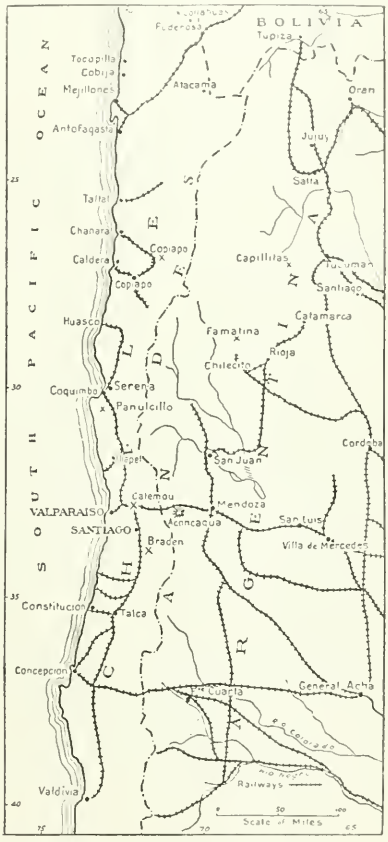
Sr. Felipe Herrera is producing regularly about 30 ounces of gold per day with his Tremain stamp-mill. His success has induced other owners of small gold mines to erect small plants. A Tremain is going in to Petorca this coming week and will crush ores from the Durazno mine. Another small mill is being erected in La Ligua. This plant is one of the last things to arrive in Chile from Germany.

The Murex people have a fine working-scale testing-plant at Santiago and are making numerous tests of copper, silver, tin, and gold ores. As Chile is profusely supplied with iron ore, it would be difficult to find a place where the necessary magnetite was not right at hand. And as the country is narrow, supplies of oil and fuel are usually easily obtainable. A large waste-dump of copper ore at Batuco is to be treated by the Murex process, and negotiations are under way for a plant for the Espino mine, near Pedegua.

The condition of the nitrate market is far from satisfactory, the price ruling today close to $25 per ton, export-duty paid, and on board ship. This is far below the ruling price before the War, and it is to be expected that California fruit-growers will take advantage of the low prices. Although the shipments of nitrate are sure to be less on account of Italy going into the fight, a number of nitrate plants are planning to begin operations again, and this in the face of a heavy drop in the leading nitrate shares.

The jump in prices of zinc and quicksilver has started work on several mines yielding these metals. One district called Punitaqui was for many years a producer of quicksilver, but has been closed-down for forty years. An energetic group has re-located the district and firebrick is already on the way to the mine for the construction of the furnaces. Practically no machinery will be required, as the deposit is so large that no underground work is necessary for a long time. There are inquiries for quicksilver from Europe, which would indicate that the metal is used in some way in shooting people.

There are a number of small mines that can produce



zinc ore, and one near Los Vilos has 100 tons of high-grade hand-sorted ore at the port for shipment.

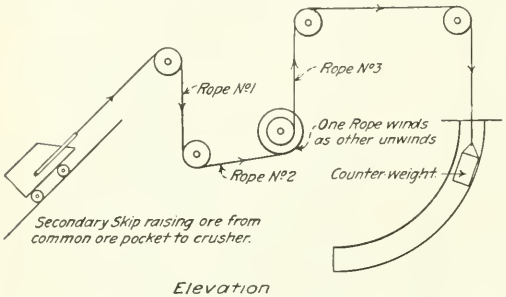
Freight-rates on ores have doubled, and in some cases are three times former rates. This makes difficulties for the producers, but not in proportion to the increased prices, so that mining is now actually on a better basis than before.

In view of the excessive prices asked for coke, careful tests have been begun to attempt the manufacture of coke from native Chilean coal. Practically all the coals here are Tertiary and do not therefore compare with the highest grades found elsewhere. Nevertheless, it should be possible to make a coke sufficiently strong to bear the burdens in the small furnaces used.

Mechanical Features at a Lake Superior Iron Mine

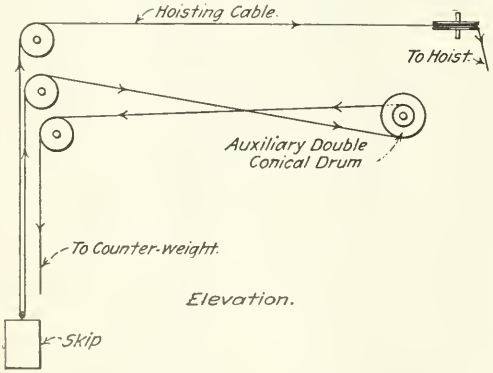
By P. B. McDONALD

Mines have individuality reflecting the personal abilities and shortcomings of their superintendents and engineers. Thus one property will be exceptionally well handled underground, with possibly its clerical work notably neglected, in which case it will be apt to attract good miners, but will impress visitors as being rather



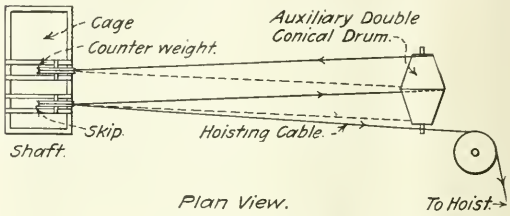
Elevation

slipshod. Another mine will emphasize its mechanical features, due perhaps to the ingenuity and talents of one of its engineers with a bent in that direction. The Republic Iron mine on the western Marquette range, Michigan, lately sold by the Cambria Steel Co. to the Cleveland-Cliffs Iron Co., is a mine of the latter class. It is a high-grade ore producer, mining a hard specular hematite, requiring good miners. Being the only mine



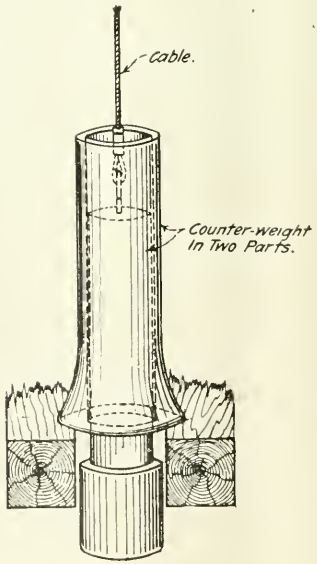
in the vicinity, it has attracted a desirable class of workers to the village of Republic, and has maintained excellent relations with its employees. Due to the mine being opened in the early days, and to an irregular shaped ore deposit, the original arrangement of the equipment and shafts were not as would have been planned if the development had been foreseen. Thus, when an engineer with mechanical ability took charge some years ago, there was a chance to improve matters.

The mine now has various mechanical features showing the result of his work. One of them is a stock-pile or trestle car for use in making an ore-dump starting along a side hill, with an arrangement for dumping only on one side. This car is entirely of steel; it has a long low truck with eight small wheels, and the ore or



rock is contained in a box of triangular cross-section that can only dump to one side.

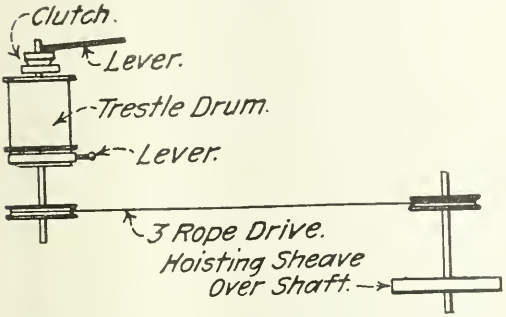
Another peculiar arrangement is the counterweight at one of the ore-hoisting shafts. This shaft is vertical and



is mostly for hoisting from depths of from 500 to 1000 ft.; it has only one compartment for a skip, which is therefore balanced by a counterweight.

In addition to the regular hoisting-cable fastened to the skip is a second cable that passes over a small sheave and to a double conical drum. From the drum it passes over another small sheave to the counterweight. The drum, being conical, helps to accelerate the load at the start of hoisting. When the skip is dumping, the load

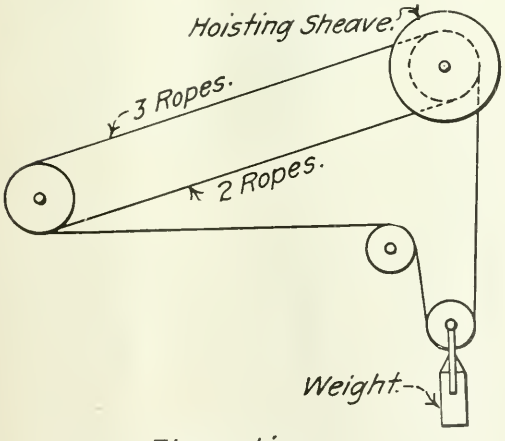
is not so great as only one end of the skip is being raised; to take off some of the weight of the counterweight at that time, it is made in two parts, the outer of which is lifted off by timbers at the bottom of the shaft as seen in the sketch. Later the outer counterweight is raised by a shoulder on the inner counterweight. It may be stated



Plan View.

in passing, that some Lake Superior mines are counterweighting their man-cages by a long 11 in. steel cylinder or shafting that moves in a 12 in. iron pipe, making a compact and space-saving counterweight with no danger of anyone getting caught by it.

Stock-pile or trestle cars at the Republic mine are run out by gravity, the trestle being inclined for that pur-



Elevation.

pose, and a clutch on the trestle-drum being thrown out to allow it to revolve freely. The car is pulled in as follows: On the same shaft as is the hoisting-sheave is a smaller sheave, which, by a rope-drive, runs the small drum on the trestle. As the regular hoisting-sheave revolves, the car is pulled in.

Another unusual feature is the economy secured in crushing ore and sub-hoisting ore to the crusher, using one engine alternately for these two purposes. It is usual at many hard-ore mines to dump ore from the skip direct into a gyratory crusher, which rests on the ground on a concrete foundation, and then to hoist the crushed ore to a loading-pocket or to the stockpile-trestle by a secondary hoisting-engine, possibly one man tending the crusher and the secondary hoist. Some later installations at large mines have followed the copper country practice of only hoisting the ore once, dumping the skip direct into the crusher, but placing the crusher high enough from the ground so that cars can be loaded underneath. The iron mine operators have placed their heavy gyratory crushers on a separate foundation from the head-frame, as opposed to the copper country practice of placing a jaw-crusher in the shaft-house, where it shakes things a good deal. At the Republic mine one engine hoists ore from a common ore-pocket below the railroad track, and serving several shafts, to the crusher, and then furnishes the power to crush it. The sketch gives an idea of the arrangement, showing three separate ropes, and a counterweight that slides in a curved path.

Improvements at Anaconda

At the concentrator, No. 1 section, which was recently re-modeled to provide for the installation of oil flotation, is successfully treating ore at the rate of 2000 tons per day. The tailing assays well within the limits expected. No. 2 section is now being changed to provide for the use of a similar plant. Rapid progress is being made with the work. It is expected that tearing out the old machinery and constructing the new 2000-ton unit, ready for operation, will be accomplished in 33 days.

All four furnaces in the east reverberatory building are now operating on pulverized coal. Three of them are 143 ft. long; the fourth, which was the first furnace to be equipped for coal-dust firing, is 124 ft. long. These four are working well. They are smelting a greater amount of material than the eight grate-fired furnaces formerly did. All furnaces in the west building are now being re-built. They will be ready for operation when the No. 2 roaster plant is completed. In the coal pulverizer plant the pulverizer building is now completed. Work is progressing on the installation of the remainder of the crushing, storage, and drying equipment.—*The Anode.*

METALS produced by the Mt. Lyell properties, Tasmania, from August 1903 to March 1915 are as follows: copper, 194,261,760 lb.; gold, 175,627 oz.; and silver, 6,979,567 oz., from treatment of 4,193,789 tons of ore. Including production prior to that date the total is 303,074,240 lb. copper, 331,379 oz. gold, and 11,100,968 oz. silver. Dividends total $12,973,000.

GOLD PRODUCTION of Peru in 1914 totaled 670 kg., equal to 21,400 oz., from 12 departments of the republic. This bullion was sent to the mint at Lima, which executed coinage valued at Lp. 123,763, or about $594,062. The largest gold producers are the Cotabambas Auraria, Chuquitambo, and Aurifera Anadray Pasco. Their total was 417 kilograms.

Mining in California

By CHARLES G. YALE

*There are few changes to be noted in the mining industry in California for the first six months of the year, as compared with the conditions in 1914. Some gain in gold yield is apparent, however, the United States Mint at San Francisco, and local smelters and refiners having received $598,822 more California gold in the first five months of 1915, than in the corresponding period of 1914.

There was plenty of water available for mining in the winter of 1914-15, not only for gravel but for quartz miners, so that the working season for hydraulic mining has been longer this year than usual. The placer miners throughout the State took advantage of the abundance of water in the spring and summer months; and at numerous points, where little had been done for years, considerable gold was taken out. Drift mining continues inactive, with no new developments of note except that at the old hydraulic camps of Dutch Flat, in Placer county, long idle, the Federal Drift Mining Co. has discovered rich gravel in driving a tunnel connecting with the old Rough and Ready workings.

Dredge mining continues to be prosperous and productive. Some few changes have taken place in the movement of the dredges. The United States Dredging Co., which has its machine on Middle creek, three miles from Redding, and some other companies are prospecting ground in the vicinity of Igo, Gas Point, and in Happy Valley, in Shasta county. The Pacific Gold Dredge Co. has started a new dredge in Butte Creek district, six miles from Chico.

The Oro Water, Light & Power Co. has completed a dredge on the Mokelumne river, near Clements. Part of the machinery from the old Empire dredge was used in this. The Yuba Consolidated Goldfields is building a new 16-cu. ft. dredge with steel hull at a cost of $400,000. It may be said that the dredging companies that bought a lot of land along the Yuba river have stopped the old placer miners from working along that river. The Shasta Dredging Co.'s dredge, which has been operating at Horsetown, on Clear creek, has been moved 12 miles to a point near Gas Point.

In connection with quartz mining, it may be said that there has been very slight change. An unfortunate setback is that of the pending apex conflict between the Empire and the North Star companies, at Grass Valley, the two largest deep producers in the State. There are contentions of trespass, which arbitration has failed to settle, and now the matter is to come before the courts.

The North Star has constructed a large steel frame at the Central shaft and a new hoist to operate to a depth of 7500 ft. The Empire Mining Co. has erected a new mill of 60 stamps with a capacity of 300 tons per day. In conjunction with a 20-stamp mill operated on the Pennsylvania, the Empire now has 80 stamps at work.

*Report made to the Director of the U. S. Geological Survey.

The Bunker Hill Co., operating near Amador City, has increased its output by adding a Hardinge mill.

The Plymouth, in Amador county, re-opened in 1914, has had a prosperous year and is now considered one of the best producers in the State. The South Eureka continues to run its 80-stamp mill and the Central Eureka is becoming prosperous. Work has been started on the Providence shaft of the Champion mines at Nevada City, and the shaft, which is 800 ft. deep, is being repaired, and a new frame and hoist is being erected.

The Standard mine at Bodie, in Mono county, has

passed into the hands of J. S. Cain, owner of the South End group.

In regard to copper mining, the conditions at present are much better than they were last year. The Mammoth Copper Co., in Shasta county, is now running to its full capacity. The concentrating plant of the Mountain Copper Co., near Keswick, has been completed and put in use, and the smelter on San Francisco bay has again been blown in. At the Dairy Farm mine, in Placer county, a railroad nine miles long, to carry the ore to Sheridan, has been completed. The Balaklala Copper Co., in Shasta county, has repaired the tramway and other surface structures and the property is being put in shape for a heavy output as soon as arrangements for ore reduction have been perfected. This ore will probably be shipped to the Mason Valley smelter or the Tacoma smelter, and the output is expected to be 500,000 lb. of copper monthly.

The Calaveras Copper Co. has put in an oil-flotation plant at its big copper mine. The old Copper King mine, near Fresno, will shortly be started, it is probable, and it is expected that it will turn out a thousand tons of 3% ore monthly.

The Wah Chang Mines, China

By H. T. LIANG

History. The Wah Chang Mining & Smelting Co. was organized in the 34th year of Kwang Hsü (1908) and a patent to its smelting process was given by the Chinese government. Therefore no person or company can use the same process for antimony ore anywhere in China and no antimony-smelting company is allowed to incorporate in Hunan province for 10 years following 1908, no matter what processes it plans to use. In 1908 this property and the Kiu Tung antimony mine were consolidated. Previous to 1908 the Kiu Tung antimony mine smelted its stibnite ore into crude antimony by native methods. After the consolidation the ore was treated by the volatilization (Herrenschmidt) process.

The Wah Chang smelter is situated near the Si-Hu bridge, at Changsha, in Hunan province. The Kiu Tung mine is at Pan-chi, 46 miles from the Yi-yang district and about 100 miles from Changsha.

Geology. The country rocks near Pan-chi are old crystalline slates, broken through at several places by granite. The intrusion of the eruptive magma in part has tilted the old slate rocks at high angles and elsewhere has given rise to lateral displacements. These phenomena are to be seen in the valleys formed by erosion.

The absence of fossils in the slates and eruptive rocks renders difficult the determining of the age of the rocks and of the time at which the ore deposit at Pan-chi was formed. Only by analogy with the geological formations of the antimony deposits in such remote districts as An-hua and Sin-hua is it possible to estimate the geologic age. It is probably Paleozoic. In the ore deposits at Pan-chi it is important to note that no lateral displacement but only tilting of the slate is to be observed. The dip of the strata is steeply inclined or even vertical. Therefore, the veins of the Pan-chi mine are likely to persist in depth and disturbances in the regularity of the dip are much less likely to occur. Mining operations up to the present afford justification for this opinion, as down to the deepest level the orebody is of a uniform structure.

The lodes are of simple geologic structure. Presumably metalliferous solutions circulating in fractures formed by horizontal displacements, caused by the eruption of the granite, have undergone chemical reaction with other metals, such as iron, precipitating antimony sulphide in the fractures.

The antimony deposits of Hunan and Hupeh contain only small amounts of arsenic, as the following quotation from an article by W. R. Schoeller in the *Journal* of the Society of Chemical Industry indicates. "The Siang-kiang would appear to form the eastern boundary of the antimony belt. The district situated between that river and the Yuen-kiang and of which the city of Sin-hao may be said to be the centre, produces the purest and richest stibnite ore, a typical ore assaying 57.64% Sb and 0.127% As, with traces of Pb and Cu. However, the arsenic is usually well below 0.1%. The gangue amounts to about 15% and consists of quartz, occasionally mixed with schistose rock. The mineral is most frequently coarsely crystalline, showing long stout prisms of strong lustre. Massive stibnite is not uncommon, and the richest ores are of this variety with an antimony content of 60 to 65%. To the north of the Sin-hao district the de-

PART OF HUNAN PROVINCE.

posits become poorer; near An-hao there occur ores averaging 48% Sb, with 0.06% As and negligible quantities of lead, copper, and zinc. They are granular texture and present a dull lead-gray appearance. Low-grade ores are also known to occur. A 25% ore showed beautiful isolated crystals several inches long, embedded in a slaty gangue. Another ore (28.94% Sb) of extraordinary hardness consists of an intimate mixture of quartz and stibnite in fine-grained masses. Both ores were practically free from arsenic. Passing into southwestern Hupeh the ore deposits show an increased proportion of arsenic, a sample giving 51.75% Sb and 0.43% As.

"The same may be said of stibnite and crude antimony from the provinces of Kwei-chow, some of which finds its

way down the Yuen-kiang. Specimens were examined with the following results:

1 Ore Sb 62.99%, As 0.846%, Cu Zn—trace
2 Crude Sb 69.85%, As 0.46%
As 0.303%"

METALLURGY. The company smelts its stibnite ore by a simple volatilization process. The composition of the ore from the Pan-chi (Yi-yang district) is as follows:

a.	Antimony 32%	Sulphur 11%	Silica 44%	
	Iron 12.85%	Arsenic 0.5%		
b.	Antimony 25%	Sulphur 10%	Silica 53%	
	Iron 11.8%	Arsenic 2%		

The composition of antimony regulus, or the metal, is as follows:

1	Sb 99.760%,	As 0.090%
2	Sb 99.950%,	As 0.050%

The metals produced by the Wah Chang Company have been carefully analyzed by W. A. Cowan, who published his results in the *Transactions* of the American Institute of Metals, Vol. VIII, 1914. It is important to note that the Wah Chang metal is purer than either the Cookson's 'C' brand or Hallett's 'H' brand.

"The samples of antimony were obtained in a similar way, by taking individual ingots from lots bought in the market of the following brands: Cookson's, branded 'C'; Hallett's, branded 'H'; Japanese, branded 'M C'; Chinese, branded 'W. C. C.' with two overlapping circles 'OO'. The Cookson's and Hallett's are both produced in England, probably largely from imported ore.

"The results represent respectively only the one ingot of each brand and not, necessarily, the average composition, except in so far as the manufacturer would guarantee each ingot to come within certain specifications. Neither should it be supposed that the composition of any of the brands represents the characteristic production of the country of its origin.

"The samples of antimony were prepared for analysis by breaking up the whole of each ingot, crushing, quartering, and powdering, finally putting two pounds of each sample through a 100-mesh sieve. They were then carefully mixed and divided into portions for the different analyses.

"The determinations reported here show also the need of much more work being done. The results so far obtained are given in the table below:

METALLIC ANTIMONY ANALYSIS

*—By difference."

MARKET CONDITIONS. The market for antimony is a peculiar one, as the prices are not according to the purity or grades, but their brands. The following statement was published in the MINING AND SCIENTIFIC PRESS on November 14, 1914: "Cookson's brands are more in demand than Hallett's and both command better prices than the Hungarian or Chinese antimony. The average price of Chinese brands is not available, but is usually about 1½ cents less than Cookson's. It is an interesting feature of this situation that careful analyses recently published by Mr. W. A. Cowan in the *Transactions* of the American Institute of Metals, show that although Cookson's antimony is purer than Hallett's, the Chinese Wah Chang antimony is purer than either. Recently Hallett's antimony has been most in demand, and the inference seems inevitable that antimony is sold on the basis of its trade-mark rather than its quality."

The Wah Chang and Kiu Tung companies were awarded the prize of the first class at the National Exhibition at Nangking, China, in the second year of Hsuen Tung, 1910.

THE DISTINCTION between agate and onyx is not apparent to everyone, as is indicated by the samples of the two minerals received by the U. S. Geological Survey with requests for information. Onyx marble, or Mexican onyx, is composed of calcium carbonate or banded limestone. True agate is a variety of silica. Onyx marble is much softer than agate and is rarely used for gems, but when onyx is obtained in pieces of sufficient size it is cut and polished for small ornamental objects like inkstands and paper weights, as well as for table tops and soda-water fountains.

MANGANESE production in the Caucasus district of Russia in 1914 totaled 652,354 tons, a decrease of 302,290 tons. In the first half of the year the output was 9.46% over that of the same period of 1913. The decrease for the full year was due to military operations.

OIL PRODUCTION of Illinois in 1914 totaled 21,919,749 bbl., worth $25,426,179. This is a decline of 1,974,150 bbl. Stocks at the end of the year were 13,563,743 barrels.

Mining in Colorado

By GEORGE J. BANCROFT

The effect of the European war on mining enterprises in Colorado is being felt more and more. On the whole, that effect is beneficial. The War has broadened the industry. It has made our mining men take notice of minerals heretofore passed over as of little account. It has further thrown us on our own resources. Promoters do not go "back East" to raise money any more. They get it close at home. Local capital is notoriously economical, and this again has had a good influence on operations. An important enterprise has recently been financed with local capital at Salida. The Peerless M. & M. Co. will re-open the famous old mine called the North Pole, situated above Salida on the boundary between the Chalk Creek and Monarch districts. The ore contains silver, lead, and zinc. The vein is 40 ft. wide in places. It has already been tapped at considerable depth by a cross-cut adit 1200 ft. long.

Another instance of local financing is seen in the success of John H. Nichols (recently general superintendent of the El Paso mines at Cripple Creek) in raising $100,000 in Colorado to re-open the old Freeland mine at Idaho Springs.

Shortly before the untimely death of Franklin Guiterman, of the American Smelting & Refining Co., he spent some time in Denver. He said to the writer: "The War has opened our eyes to our weaknesses and opportunities. We have for too long a time let the Germans handle the unusual and rare metals, in which there is small tonnage consumed but a very big profit. The volume of business in any one metal may be small, but take all the rare metals together and the business is altogether too big and too profitable for us to let foreigners take all the cream. I have been urging our company to erect works to handle the rare metals, and already we have made some progress in that direction." That Mr. Guiterman's wise and timely advice has not gone unheeded is shown by the activity in the Daly district, above Empire, where 100 men are busily engaged in mining molybdenum; in Boulder county, where the output of tungsten is rapidly increasing; in the remarkable strides made by the Golden porcelain works, their product supplanting German-made laboratory porcelain in many American laboratories; in the precious gem industry started by Prof. G. M. Butler in Fremont county, Colorado; and in the new titanium industry, which is gradually crystallizing into tangible form in southern Wyoming.

The past month has been one of great activity in the installation of mining equipment. The Mary McKinney at Cripple Creek has installed a large new electric compressor and hoist. The machinery for the new gold dredge for the Derry Ranch placer, on the Arkansas river, 12 miles south of Leadville, has arrived on the ground and is being erected on the boat. This dredge will be a material factor in increasing the gold output of Lake county. The Derry Ranch is a well proved placer, and the wonder is that a dredge was not built years ago. The explanation probably lies in the fact that the proved ground was somewhat limited in extent and so a great enterprise had to hang fire for several years pending the drilling of a few more test-holes.

The Western Colorado Power Co., at Telluride, has expended about $8000 in improvements and betterments. James McNeece of Leadville is re-modeling the shaft-house of the Fortune mine and installing a hoist. He has opened up the property from the Yak Tunnel and already proved the existence of profitable ore in the lower contacts. When the hoist is installed, he will clean out the stopes on the upper contacts and go after the zinc ore that was left behind years ago when zinc was a liability instead of an asset to the producer.

The Iron City mill at Black Hawk has been re-modeled and put in operation. The new cyanide mill of the Jerry Johnson, at Cripple Creek, is nearing completion. The Gordon Tiger property at Twin Lakes, Lake county, is working a small force of men preparatory to building a mill. The Idaho Bride M. & M. Co., near Idaho Springs, has completed the installation of a compressor plant, and development work is progressing in a satisfactory manner.

Among the notable discoveries of ore may be mentioned the high-grade gold ore in the Pro Patria adit at Rico. Rico is noted as a producer of silver, lead, and zinc. Gold, by itself, has never been suspected or sought after; hence the discovery of this ore, which had lain exposed on the tunnel-walls for many years, opens up the possibilities that there may be many bodies of similar ore in the district. The ore-shoot is reported as small but very rich. It is on a north-west and south-east vein, which series has always been considered barren. About $10,000 has been realized from ore-shipments to date.

The Kansas Leasing Co., working through the Argo Tunnel, has opened-up a nice body of ore in the Kansas vein, which was one of the famous early producers of Quartz Hill, Gilpin county. This strike is of unusual importance because it may lead to a general resumption of work in the Quartz Hill mines. Although this famous group, which has produced $50,000,000, was pierced at great depth by the Argo (or Newhouse) Tunnel several years ago, yet the water lowered very slowly and little ore was found in the adit.

Another epoch-making strike is that in the Ponsardin mine at Leadville. This is one of the mines affected by ex-Governor MacDonald's pumping coalition for the 'Down Town' mines. The discovery of a large body of zinc-lead ore in the Ponsardin, as the water lowered, has given additional enthusiasm to those who are backing the project.

At Cripple Creek "things never looked better," as one big operator tersely put it. Progress in that busy and complex camp is so varied that it is impossible to detail it in an article of acceptable length. In brief, new ore-bodies are being discovered at all depths. Working costs are being lowered. Old mines are being re-opened; notable among these is the famous old C. O. D. The Roosevelt drainage adit is daily tapping new water-courses and so lowering the water-level.

Non-Metallic Products

Compiled by SAMUEL H. DOLBEAR

Kaolin Refining at Ione, California

In the vicinity of Victorville, California, one of the first clay-washing plants in the state was erected several years ago. This attempt to produce a refined product for use in the arts was not entirely successful, although the material was used in the aint and other industries in southern California. One of the serious difficulties encountered at this plant arose through the fact that the buildings could not be made air-tight. Victorville is situated on the Mojave desert, where sand abounds and vegetation is scarce. In spite of all precautions, fine drifted sand found its way into the finished product, this grit rendering it useless for many purposes.

No such problem as this confronts the Products Development Co., at Ione, in its clay-refining plant, which has now been in operation for a year. In contrast to the arid conditions at Victorville, it has been found that winter rains have limited the operating season at Ione to about seven months each year. The refined clay, after treatment in the water-flotation plant, is distributed over drying-floors, solar evaporation being utilized to dry the product before shipment.

The refining of this clay is entirely a mechanical process in which the clay itself is separated from the sand embedded in it. This sand constitutes about 40% of the weight of the crude material, and is of particular interest on account of its high silica content. Analysis shows 99.5% SiO_2. It is one of the few sands found in California of sufficient purity to be used in glass-making. Experimental lots of several hundred pounds have been used for this purpose by San Francisco glass manufacturers and have been found as satisfactory as Belgian sand, which has been imported previously in large quantities. As the latter material is not to be had at this time, the Ione deposits have solved at least one local problem arising from the European war.

When mined from the bank, the clay is delivered to a cylindrical disintegrator. It then passes into the flume through which water moves slowly. The disintegration becomes complete in this flume, the sand readily settling and the finely divided clay remaining in suspension and passing into settling-tanks. There are three of these, each having a capacity of 20,000 gal. The clay settles gradually to the bottom of the tanks, and the water is decanted. Enough remains so that the product is now a thick sludge, this being pumped to a Kelly filter-press. When dry, the clay is pulverized in a cage-mill and is then ready for shipment. This plant is capable of producing 15 tons per day of refined kaolin.

The company is now building a second unit having a capacity of 25 tons per day of refined kaolin and 15 tons of sand. In this unit the clay will be treated dry and the separation made by a pneumatic process. A small experimental plant of this type was built in San Francisco before this new construction was undertaken, the experiments having indicated that the process was suitable for this work.

It is expected that the completion of this equipment will make possible operation at all seasons of the year. The product is used largely in the manufacture of enamel, sanitary ware, and to some extent by paint and linoleum manufacturers.

Borax

The production of borax in the United States has remained about normal during 1914. Depressed business conditions, it is true, have largely reduced local consumption, but the European war has disturbed production in other countries, and this deficiency has been partly supplied by the California mines, which are the only source in North America. Canada usually imports large quantities from England, but since the declaration of war has drawn upon American refiners for its requirements. The refiners of Austria and Germany have also been badly crippled, and the mines on the Sea of Marmora have been closed by the participation of Turkey in the War.

The world's commerce in borax and boron compounds is largely controlled by Borax Consolidated, an English company with headquarters in London. This company has refineries in England, France, and the United States, and has supplied the German and Austrian refiners with borate ore fro mits Chilean mines. The Turpish mines are, however, the older producers, and were worked years before the South American deposits were opened. The former have produced about 14,000 tons annually during recent years.

The California mines supply practically all of the borate ores used in this county. Three companies are engaged in this work, the largest of these being the Pacific Coast Borax Co. Since the sale of the F. M. Smith interests, this company has been controlled by the Borax Consolidated, with which it had a working arrangement prior to that time. The Pacific Coast company completed much construction work during the past year, including a branch railroad connecting its Biddy McCarthy and Monte Blanco deposits with the Tonopah & Tidewater railroad at Death Valley Junction, and a calcining plant at the Junction. In this plant the low-grade ore is roasted before shipment. The new railroad opens up some of the richest deposits in the Death Valley region, these being inaccessible heretofore owing to long overland hauls by wagon.

The Sterling Borax Co., with mines situated six miles fromLang, in Los Angeles county, is the second largest producer in California. A branch railroad connects these deposits with the Southern Pacific railroad. Dur-

ing the past year the company is reported to have mined about 15,000 tons of ore. This is divided into two classes: the first grade contains about 31% anhydrous boric acid, the second about 20%. All of the ore is roasted at the mine before shipment, thereby eliminating the impurities, which consist of clay, pandermite, and water. The colemanite content, upon being roasted is reduced to a fine powder, while the clay and pandermite present retain their original shape. The valuable portion is then readily separated by screening.

After a period of idleness lasting several years, the Russell Borax Mining Co. has again resumed production at its mines in the Ventura district. The control of this company has been acquired by the Stauffer Chemical Co. of San Francisco. During 1914 the period of operation was about seven months, and 3800 tons was produced. This ore gave an average of between 37 and 38% A.B.A.

The total production of borate ore in the United States for 1914 was probably about 65,000 tons, although official figures for this period are not yet available.

Refineries are operated in the United States at Bayonne, N. J., Brooklyn, N. Y., New Brighton, Penn., Chicago, Ill., and San Francisco. The San Francisco refineries are operated principally to supply Pacific Coast and Japanese trade.

At a point four miles west of Rich station in the Kramer district, San Bernardino county, colemanite was discovered in 1913 while drilling for water on a ranch. Mineral locations were filed on the land, these being sold to John Ryan, general manager of the Pacific Coast Borax Co. The purchase price was $4000, of which $1000 was paid in cash. The contest between the mineral and agricultural entrants was decided in favor of the former, the evidence showing that the colemanite body was encountered at a depth of 369 ft. below the shale, and continued until a depth of 410 ft. was reached. The testimony brought out the statement from Ryan and his engineers that the deposit was considered sufficiently valuable to justify operation, the ore being exceptionally high-grade. Some of this ore gave an analysis of 47.9% anhydrous boric acid; theoretically, pure colemanite should run 50.9%.

Chilean borate deposits have been the largest producers for many years, the yield from this country being usually about 75% of the world's production. The mines of Chile, as well as those of the Argentine and Peru, are controlled by the British company.

It is expected that Peru will shortly become a large producer through an agreement made by Borax Consolidated with the Peruvian government. This arrangement provides that the company shall build furnaces capable of treating at least 40,000 metric tons of borate ore annually, and at its option, the company shall construct either a railway or tram-line connecting the mines near Arequipa with tide-water.

Some borate ores are annually mined from the British company's deposits near Tres Morros, Argentine. This ore is not sold, its production being incidental to the performance of annual labor required by the Argentine statutes. The cost of transporting this ore to a shipping-point, and other high costs, will likely prevent the commercial exploitation of these deposits until the cheaper sources have been exhausted.

Dead-Burned Magnesite

California magnesite mines yielded about 12,000 tons in 1914, some of which was sold at somewhat higher prices than those prevailing in the previous year. This industry will probably suffer some reverses during the present year unless producers are prepared to offer a dead-burned product for use by steel manufacturers. American magnesite is purer than much of the foreign article, and when properly selected and burned, is highly satisfactory in Sorel or magnesian cement. As such it has found an increasing demand in the manufacture of so-called 'sanitary floors.' These floors have distinct advantages over those of cement concrete and they are cheaper than tile floors. Magnesite floors may be layed over large areas in a solid mass without cracking, they do not absorb moisture, nor dust, as in the case of concrete. Building construction, however, is at a low ebb, and is likely to continue so for the present. For this reason the demand for light-burned magnesite has fallen off during the past few months, while there has been active inquiry for steel-makers' grade. The latter does not seem to be available here, in spite of the disposition of purchasers to secure a supply here. Austrian magnesite contains an appreciable percentage of iron oxide, and is preferred in open-hearth work for this reason. The presence of this impurity results in the lowering of the point of fusion, and at a given heat the magnesite becomes plastic. It is then tamped into place, and on continued heating it again becomes hard or 'sets.' On account of its high degree of purity, the California material possesses no such virtues, although one California manufacturer has considered a plan of adulterating his product by the addition of hematite.

Refining Manganese at Alameda

After the many unforseen delays that usually precede every new enterprise, the Western Manganese Co. has commenced refining manganese ore in its plant at Alameda, California. In February of this year the company purchased the Old Ladd manganese mine in the Livermore-Tesla district, which was probably the largest producer in the state 20 years ago. The mine was sold in 1902 to the Louraine Mining Co. by the Caires, and subsequently passed into the hands of the now defunct California Safe Deposit & Trust Company.

In the Western Manganese Co.'s plant, which was described in detail in the issues of the Mining and Scientific Press of January 30 and February 13, the ore is crushed and refined to a high degree of purity in order to meet the requirements of the manufacturers of dry and LeClanche cells, glass, terra cotta, paint, and chemicals.

Since the purchase of the mine, development work has resulted in the exposure of a mass of excellent ore. This orebody had been reached by the workings of some prior owner and subsequently, for some reason, concealed by fills of waste rock.

Concentrates

Readers of the Mining and Scientific Press are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

Gypsum is soluble in 500 parts of water and completely soluble in boiling hydrochloric acid.

Clastic is a geologic synonym for fragmental; it comes from the Greek word *klastos*, meaning broken.

Amalgam is a mixture of gold with mercury, made easily on account of the fact that mercury exists in a molten state at the ordinary temperature.

Boring holes in rubber corks is somewhat troublesome. By wetting the cork and borer before and during the operation holes are easily made. Always start at the smallest end in boring corks.

Baltimorite, a hydrous silicate of magnesia, is a white to bluish fibrous mineral associated with serpentine. It can be used for packing steam-pipes, etc., and roofing material, like asbestos.

Where two contiguous claims, one having timber on it and the other none, are held by one owner he may take the timber from one claim and use it for development work on the other.

Mercury solidifies at −40°C. and boils at 360°C. It begins to vaporize at 15°C., if not lower; and of all the metals it is the worst conductor, its conductivity being 5.33 as against silver at 100.

Lead nitrate has been used as a substitute for lead acetate at some South African cyanide plants, the supply of the latter being cut off by the War. It was found to be satisfactory but more expensive.

Wire-rope guides were used with great satisfaction at the main east shaft of the Inspiration mine, Arizona, while it was being concreted. During this work flexibility was desirable; the ropes proved to be so.

Sun-power for raising steam has been used on a working at Meadi, in Egypt. There reflectors of silvered-glass throw the sun's rays on a thin long vessel, made of zinc and painted black, through which the water passes.

Flouring is the minute sub-division of mercury by mechanical means, and 'sickening' is the rendering of such a condition persistent by the coating of the globules of mercury with a film of foreign substance preventing coalescence.

Few claims within Forest Reserves that are presented for patent comply with all the Federal and State laws in every particular. This is usually due to lack of knowledge, as the requirements are different in different states, and as most prospectors and miners operate in several states they confuse the various regulations.

Pumps mounted on scows were used for draining Kerr lake, Ontario, because the shore-line constantly changed as the water-level was lowered. The scow was kept near the shore in order to avoid using pontoons to support the pipe-line.

Cost of drill-steel and sharpening includes not only the cost of the steel and the wages of the blacksmith, but also its proportion of total shop-cost, the delivery of sharpened steel to the faces, and the returning of dull steel to the shop.

Sintering devices, such as Dwight-Lloyd machines or Huntington-Heberlein pots, cannot be used with lead-ore mixtures that contain over 15 to 18% sulphur. When more is present, the ore must be subjected to a preliminary roast.

Cut-out shots can be prevented to a considerable extent by using regular-burning fuses and allowing a longer time interval between the different shots. No detector devised to indicate cut-out shots has so far proved satisfactory in practice.

Linarite is a basic sulphate of lead and copper, occurring often in deep-blue crystals. It can be distinguished from azurite, the blue copper carbonate, by the acid test, for it will not effervesce when acid is applied. The mineral is named after Linares, in Spain.

Caving of ground in mines is usually accompanied by concussion of the air, which is destructive for considerable distances from the cave itself. Broken rock occupies about 50% more space than when in place, so that a sudden caving displaces a great volume of air.

Mine waters may be acid near the surface, but are invariably neutral or alkaline in depth. In some mines the decrease in acidity with depth has been shown by analyses from different levels. The decrease of acidity is accompanied by a similar decrease in the salts of heavy metals present.

Tube-mill pebbles are sold in eight sizes, the smallest varying between 1 and 1½ in. diameter and the largest between 4¾ and 7 in. diameter. Danish pebbles are preferred because of their homogeneous character, giving the longest service and consequently the least cost per ton. They cost $11 per long ton in Denmark, $15 per ton in New York, and much higher figures delivered at the mills. Thus at Round Mountain, 72 miles by wagon-road from Tonopah, the delivered cost is $62.50 per ton. These figures explain why various domestic substitutes are not usually satisfactory—the delivered cost of pebbles, say, from California would not be much less than pebbles from Denmark, while the daily consumption of the latter is much less. The results of experiments on domestic pebbles in Nevada mills were given in the Press of January 23, last.

California Minerals at the Exposition

Many California and other mining men will be disappointed in the way in which the mineral resources of the state are displayed at the Panama-Pacific Exposition. This is no place to discuss the reasons of the arrangements, but it is a pity that some agreement could not have been made whereby an industry producing nearly $100,000,000 per year was given prominence at the Fair. Oil contributes about $50,000,000, gold over $20,000,000, copper over $5,000,000, quicksilver about $600,000, and building materials over $15,000,000 of the total, yet representative minerals of these classes are shown in three departments.

In the California State pavilion is a neat collection. Prominent features are the following: A life-size statue of James Marshall, who discovered gold at Coloma, Eldorado county, in January 1848. Below him are large samples of ore from Amador, Butte, Eldorado, Nevada, Plumas, Shasta, and Trinity counties. At the front of the exhibit at each end, is a square pillar composed of many California ores. Between these pillars are two round ones. Their bases are of Shasta iron ore and pig iron supporting blister copper surmounted by slabs of marble and tiles. A short 'adit' shows part of the 'Cosmopolitan Mines Consolidated' property. We reserve judgment on

SOUTH EUREKA MINE AND MILL, AMADOR COUNTY.

this exhibit. At the mouth of the adit is an improved Matteson ore-car, made by the Joshua Hendy Iron Works. At the back at one end of the booth is a pillar of asbestos from the Stevens mine, Shasta county. Farther along is a pillar of Heroult iron and ferro-manganese from the same county. A 10-stamp mill (20 lb. each, by D. D. Demarest Co.), with plates, No. 5 Deister concentrator, driven by a Westinghouse motor, is instructive. It is operated; clean-ups have been made, and concentrate is to be shipped to the smelter. Part of Trinity county has been transferred to the booth. This county has contributed $200,000,000 in gold. A model hydraulic mine shows the face, water-supply, two Hendy giants (Bonery patent), and sluice-boxes. A model Yuba dredge, described in the PRESS of May 29, and similar to the one in the Palace of Mines and Metallurgy, is ready for work. In addition to these features, there is a lecture room in which actual mining operations in the state are shown by moving pictures.

Rather well arranged are eight safe show-cases, really steel safes, which are locked at night. They contain many thousand dollars worth of ore and placer gold. The Amador case displays Kennedy, South Eureka, Gwin, and other mine specimens, Butte—gold ore, dredge gold, and diamonds; Eldorado—ores, nuggets, and leaf gold; Nevada—North Star, Golden Center, and other; Placer—fern-leaf gold and other shapes, owned by the county and other people; Sierra—gold ore from the Tightner, White Bear, Twenty-one, Ironsides, North Fork, and Empire; Trinity—ores and nuggets; and Yuba—a splendid lot of dredge gold and some platinum.

In a number of large cases are samples of typical ores from 226 mines in the following counties, with the number of mines exhibiting from each: Amador, 18; Butte, 24; Eldorado, 32; Nevada, 22; Placer, 13; Plumas, 25; Shasta, 38; Trinity, 31; and Yuba, 23. One case contains something of historic interest, this being a volume containing the 'Constitution and By-laws of the Ancient and Honorable Order of Independent Miners,' Jone valley, California, instituted March 19, 1853.

Mineral waters, Colusa sandstone, and a classic pillar of granite by the Pacific Granite Co., Rocklin, Placer county, are also on view.

In the Palace of Mines and Metallurgy is another California mineral exhibit. This is the result of co-operation of some mining companies and the State Mining Bureau.

Two steel safes contain specimens and placer gold from Amador, Eldorado, Shasta, Sierra, Siskiyou, Trinity, and Tuolumne counties. Visitors to the Bureau in the Ferry building will recognize the model Union Iron Works 5-stamp mill here. Large cases and benches display the following: Cerro Gordo mine, near Keeler, Inyo county—case of silver-lead and copper ores, native silver on lead carbonate, zinc carbonate, and galena; bench of building materials—granites, basalt, lava, volcanic tuff, slate, pumice, and limestone; bench with large samples of ore from Calaveras, Kern, Mendocino, Santa Clara, Shasta, Siskiyou, Trinity, and Tuolumne counties; case

VIEW NEAR THE GLOBE MINE, IN TRINITY COUNTY.

of mica, garnet, quartz crystals, tourmaline, etc.; tungsten from Kern and San Bernardino counties, Atolia being in the latter; case of mercury ores and metal from Lake, Mendocino, Napa, San Benito, Santa Clara, San Luis Obispo, Solano, Sonoma, and Trinity counties; Kern county case of sulphur, antimony, gold, silver, kaolin, etc., ores; Shasta county case with copper ores from Bully Hill, Mountain Copper, Arps, Minnie Haley, Afterthought, and Mammoth mines; asbestos, talc, magnetite, barite, and glass sand from Shasta county; copper ores from the Penn mine at Campo Seco, and Union at Copperopolis in Calaveras county; and other cases containing gold, fossils, and the rarer minerals.

Of interest is the first pig iron cast by the California Iron Co. at Clipper Gap, Placer county, on April 23, 1881, and the iron made by the Nobel Electric Steel Co. at Heroult, Shasta county.

With a painted background, representing typical California mountain mining districts, is a model hydraulic mine. It includes in operation water supply, three giants, derrick for boulders, hydraulic-filled dam for tailing, and shows the use of the clear water for irrigation.

Attracting a good deal of attention is the glass model of the Mammoth copper mine of Shasta county. The vein system and underground workings are easily followed. The company also displays ore, matte, blister copper, and photographs.

All phases of mining in California are shown by numerous photographs.

A novel, but very instructive reproduction of the oilfields of California is nearly complete on a platform above the mineral exhibit. Wells are shown by aluminum rods. The depth at which oil is struck is marked on them, and all are connected.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

JOPLIN, MISSOURI

Changes in Mine Ownership.—Porter Estate Drainage.—New Mills.—Profitable Dumps.—Sludge-Mills.—Other Activities.

Several zinc mines have changed ownership recently. These transactions have been caused by the high prices of zinc blende. It is noticeable, however, that the majority of purchasers are men who either live in this district, or who already had mining interests here. One of the deals at least involved a sum in excess of $100,000 while the others ranged in price from $50,000 down.——The O. F. & L. Mining Co., operated by Lown & Hastings, at Duenweg, sold its mill and first lease of 24 acres of the Boston-Duenweg land, to S. Y. Ramage, of Oil City, Pennsylvania, and associates. The Ramage interests already operate the Ramage-Center Creek mine at Webb City, Missouri, and are planning to construct three new concentrating plants on fees recently purchased in the west Joplin district. Another 40-acre lease of the Schifferdecker land, in west Joplin, has been purchased by the Ramage interests for $30,000. Other purchases by these people have been noted in the Press.——W. Kenefick, of Kansas City, president of the Missouri, Oklahoma & Gulf railroad, and his son-in-law, J. W. Hoffman, of Kansas City, who operates coal mines in Oklahoma, purchased from Jamot Brown a first lease on 55 acres of land which Mr. Brown owns in fee at Porto Rico, six miles northeast from Joplin. The purchase price, which is reported to be $30,000, takes in the large electrically-driven mill of the Thanksgiving Mining Co. The new owners intend to place the mine in operation at once. It had been idle two years. Sheet ore, occurring at a depth of 185 to 200 ft., will be mined. The mill, which has a capacity of 300 tons per shift, will be worked double time.——The Hurry Up Mining Co., of Webb City, of which James J. McClellan is manager, has purchased for $50,000 the 30-acre fee and mill of the Portia Mining Co. at Galena, Kansas. The mine and land was owned by S. R. Ping. Work will be carried on at a depth of 100 ft. The mill was built six months ago and has been a good producer since that time.——Herbert Taylor has purchased from B. Painter and C. G. Townsend their one-third interest in the Open Air Mining Co. on the Crown Crest land at Duenweg. Development is being done at a depth of 130 to 150 feet.

Several small companies are working on the Porter estate of 40 acres in what is known as the Kansas City bottoms, in the east-central part of Joplin, and plans are proposed by which several large pumps will be installed in the old workings of some of the famous mines that once operated on this tract. The old Kirkbride mine was one of the large producers of the Joplin district about 15 years ago, but owing to low ore prices that then prevailed, work was abandoned and water was permitted to accumulate in the old drifts. The task of draining this property has been considered difficult, but efforts will now be facilitated through the fact that large pumps are working in the immediate vicinity. Just to the south of the Porter estate, on leases of the Missouri Lead & Zinc Co., several large pumping plants are busy, and the ground has been drained to a depth of 100 ft. To the north of this land, B. F. Wurzel and associates have taken a lease on the Murphy land. They intend to begin pumping soon.

Work will start soon at the Granby Mining & Smelting Co.'s new 500-ton mill on its own land at Granby, Missouri. Construction work on the mill was started two months ago, and is rapidly nearing completion. This will be as large as any plant in the district.——Another new mill that should mean an increased production is that of the Scott Mining Co., of which Haywood Scott is manager. It is situated on a lease of the Ground & Irwin land at Duenweg, Missouri, some distance east of Joplin. Mr. Scott recently purchased the lease from J. M. Evans and others for $12,000. He has since refused an offer of $30,000 for the lease. He is undertaking something new in mill building by employing men on night shifts who work by electric lights. A plant of 400-ton capacity per shift will be completed in 22 days. The mill will be electrically equipped throughout. Mining will be conducted in sheet-ground at a depth of 190 to 200 feet.

With blende selling for as high as $135 a ton, basis of 60% metallic zinc, a figure never before dreamed of, old dumps have been leased. These old piles, once discarded as worthless, are yielding enough ore to make fair profits for those who cull them over. In many cases men, women, and children—whole families—are working on old heaps. Instances are on record in the past few weeks where a single man would clean-up as much as $200 in a week, although the average, of course, is far below this figure. For a hard worker to clean enough ore to net him $50 per week is not uncommon.

The Sweetwater Mining Co., operating on a lease of the Connor land, west of Joplin, has added a sludge-mill of three tables to its plant. D. C. Wise and Pat Tabor recently took this mine over from D. M. Sayers, and opened some new ground. The old property, which had not been productive for two years, is now a steady producer of concentrate that is above the average.——Another sludge-mill is being added to the equipment of the Liberty Bell Mining Co. on a lease of the Expansion Mining & Realty Co., west of Joplin. Five tables and concrete settling-tanks are being added at this place.

Eight-four acres of the Ishpeming, the Knight, and the Avondale lands have been taken under lease by Van Haften and associates, operators of the Gopher mine at Duenweg, Missouri. Their newly-acquired tract is situated at Carl Junction, Missouri, and one of their first steps will be to go into the old ground of the Chicago-Lehigh Mining Co., and extend drifts into the new ground. The old Chicago-Lehigh fill will not be used, as the ore will be carried by tramway to the adjoining mill owned by the United Zinc Company.——The Federated-Knight mill, of 250-ton capacity, situated on the Knight land, adjoining the ground acquired by Van Haften and others, has been purchased by T. F. Coyne. It is to be moved to a lease of the Connor land, south of Carterville, Missouri. There it will be constructed on a lease adjoining his Red Top mill, which is a heavy producer.

The verdict of the jury on the coroner's inquiry into the death of the two miners in the Longacre-Chapman mine, recently, was to the effect that the fatality was due to water and tailing coming from a cave-in of the [illegible]ury Lead & Zinc Co.'s ground. This company was found guilty of negligence in not keeping the water pumped out of the cave-in. Some time ago pumping was done for fear of such an accident, but for some reason not known this was stopped.

During the week ended June 27 the Missouri-Kansas-Oklahoma district produced 4909 tons blende, 248 tons calamine, and 1167 tons lead concentrate, averaging $101.70, $66.10, and $61.74 per ton respectively. The total value was $587,641, and for 26 weeks, $11,303,654.

GOLDFIELD, NEVADA

NEVADA EMPRESS MINE; HISTORY AND PROSPECTS.

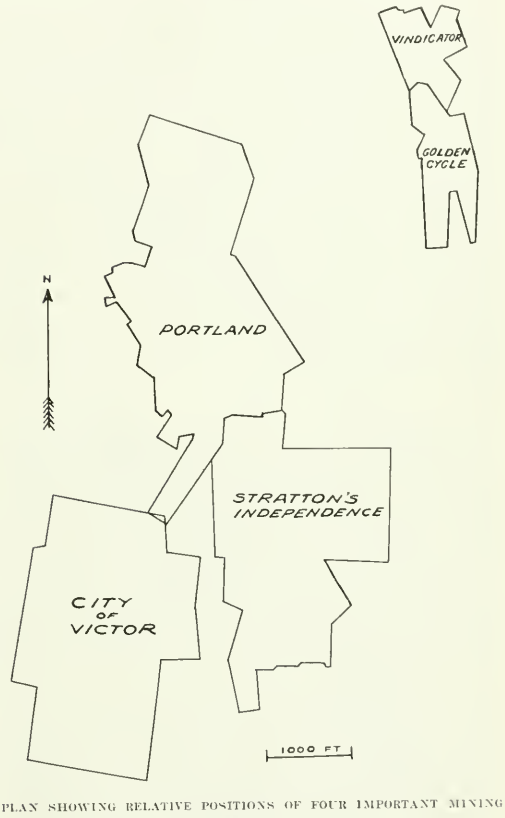
Under the direction of J. K. Turner, consulting engineer for the Nevada Co-operative Mines Co., the latter company is developing the Nevada Empress mine, 46 miles southwest of Goldfield and at the northern extremity of the Gold Mountain district. This is the old Central mine, which was worked more than 40 years ago and which contributed in important measure to the early production and mining history of southern Nevada. Specimens of ore from the Central and the nearby Oriental claims were awarded the highest prize for ore exhibits at the Centennial Exposition at Philadelphia in 1876. The Central is credited with a total production of some $300,000, most of the ore having been carried by mules across mountain ranges and desert to a mill at Austin, over 150 miles distant, some to the old Thorpe mill near Bonnie Clare, and the owner, a 'squaw-man' and recluse, is reputed to have recovered over $30,000 with his own hands, with the aid of a primitive arrastra. Another old-time miner and prospector, by name Vidovich, made his home in one of the adits, high up on the mountain, and in this adit his children were born and reared. Their makeshift bunks, shelves and fireplace, smoke-blackened and stained with grease, remain today as they were in use. Early mining operations consisted of four or five short adits, driven into the steep mountainside, high above the gulch. These adits penetrated the vein and from them the old stopes were extended, in some places so narrow as to permit barely of passage by a man lying down, the richest ore only being extracted. Each adit, in turn, exposed a continuous fault-plane, beyond which no effort was made to find the ore. Stulls of pinion pine, with wedges of the same wood, placed in these stopes and drifts over 40 years ago, appear as if put in place yesterday and show no signs of weathering, discoloration or decay. All the old workings have been connected and all are absolutely dry. The country-rock is granite, exceedingly hard, but breaks freely when once drilled. About eight years ago the Nevada Empress Co. installed a Hathaway gyratory-mill, but this proved a failure. The property was acquired early this year by the C. S. Sprague interests for the Nevada Co-operative Mines Co. A cross-cut adit has been driven into the mountain about 800 ft., nearly 200 ft. below the old adits. This has reached the fault, and a raise is now being driven to cut the foot-wall. There is already a considerable quantity of good mill ore opened, and if the ore is found in sufficient quantity in the lower adit a stamp-mill will be installed. Ample water can be secured within a short distance.

CRIPPLE CREEK, COLORADO

END OF STRATTON'S INDEPENDENCE, LTD.—NEW CYANIDE PLANTS CONTEMPLATED.

The Independence mine has reached another turning point in its career. On June 29, the mine, mill, and all property of Stratton's Independence, Ltd. became a part of the Portland estate. At three o'clock on the above date the deeds were signed at Colorado Springs, and the purchase price was paid over. At precisely the same hour in Victor, the transfer was made a reality. Philip H. Argall, general manager of Stratton's Independence, Ltd., presented to Frank Smale, manager of the mine department of the Portland Gold Mining Co., a tuft of grass with attached soil, a piece of ore, and a key. These emblems, according to an old English custom, symbolized the transfer from one company to the other of the soil with whatever buildings might be thereon, the underlying ores with whatever of precious metals they might contain, and the right of entrance to all the buildings. The Independence mine made the discoverer, W. S. Stratton, famous and wealthy by reason of its large bodies of rich ore. It has brought fame to the past managers because of the new records made in the milling of low-grade, refractory ores. It is to be hoped that the mine still has something in reserve for the new owners. It is expected that the Portland company will start vigorous development. Many applications for leases have been made. Probably all the old lessees under the Argall regime will be allowed to continue to work their blocks. The new leases will be awarded as fast as they can be taken care of.

Rumors are current to the effect that the Franklin Leasing Co. will build a cyanide mill in the district in the near future.



PLAN SHOWING RELATIVE POSITIONS OF FOUR IMPORTANT MINING PROPERTIES AT CRIPPLE CREEK.

This company was organized a few months ago, and has been working the Blue Bird property under lease. This estate is situated on the southwest side of Bull hill, not far distant from the Cresson mine. It is reported that the leasing company has secured an option on the entire holdings of the Blue Bird estate, and that Colorado Springs people have been interested in the property to construct a cyanide plant to treat the low-grade ores on the dumps and in the mine.

It is reported that heavy shipments will soon start from the Hondo property. Situated about midway between the Portland and Golden Cycle groups of claims, the Hondo mine is apparently in a good position to develop into a sizable mine. In the early days some good ore was shipped from the Sitting Bull vein on the claim of the same name. This claim is a part of the Hondo estate. Robert Mullen and associates are sinking the shaft, and a station has just been cut on No. 5 level. It is reported that in sinking the shaft a large body of good-grade mill ore has been exposed. Shipments of this ore are expected to commence soon.

THE MINING SUMMARY

The news of the week as told by our special correspondents and reflected by the local press.

ALASKA

In the U. S. Geological Survey's mid-year review for 1915, Alfred H. Brooks reports that there is every reason to believe that the mining industry of Alaska has begun a prosperous year. The present high price of copper has encouraged the continuation of development work on many copper properties on which operations were suspended in mid-summer of 1914. It is probable that about a dozen copper mines will be on a productive basis in 1915, compared with six in 1914. A considerable increase of copper production will therefore take place. The gold lode production from the southeastern Alaska, Prince William Sound, and Willow Creek districts will also be increased this year. The outlook for an increased output for placer gold is also encouraging. There will be more dredges operated on Seward peninsula this year than last. It is also probable that several new dredges may be in operation in other placer districts before the close of the season. In addition to the dredges there are a number of other placer-mining plants of considerable size that will be operated this year for the first time.

Bethel

(Special Correspondence)—Returning a few days ago from the Aniak river, I passed through the Bear Creek and Tuluksak River mining regions. A good deal of activity existed, preparing for this season's work. Lumber was being cut and supplies hauled from long distances from where it could be obtained. This hampers the development of that part of the territory, as a good many miners have to leave on account of supplies, and others who would like to come are kept out.

A noteworthy discovery was recently made on Kwisluk river that promises to be far better than any previously made. Drill-holes made by a home-made four-inch drill, from 4 to 12 ft. deep gave results from 5 to 7c. to the drill-hole. This certainly is promising.

A Lapp woman last summer on Canyon creek panned $50 from where the bedrock was exposed. The Canyon Creek properties were described in the Press of May 1, 1915. Those mines that were worked last summer were jumped this winter while the owners were down at Bethel, sending up supplies of which a good deal was already on the ground. The mines were jumped on the technicality that they were not recorded in Kuskokwim mining precinct. It appears to be a question of distinctive lines between the Nushagak and Kuskokwim precincts boundary lines. Miners called a meeting and appointed a recorder for that part of the country, until they could be informed to which mining precinct they belong, so they could forward the books of record to the proper authorities. The men who jumped the ground were at Bethel on March 17 for supplies, and went up to start work; while the owners who established a camp last summer, and have the supplies on the ground, are there making preparations for this summer's work. People here are hoping that serious trouble does not arise. It is regrettable that this has occurred. In this particular case there seems to be no question of title. The only argument is which precinct to record in. Until that time the records are on the ground free to inspection of all. It must be remembered that this particular place is over 100 miles from the nearest recording office in direct line in winter, and nearly 300 miles in summer. The law could not be too severe on such aggression, which often ends in bloodshed.

The United States commissioner at Aniak informed me that the McDonald & Bethles quartz mine near Kolmakofsky (Kuskokwim river) improves as depth is attained. Some good specimens can be seen in the commissioner's office.

Bethel, March 28.

Fairbanks

Arrangements have been made by Si Scrafford to ship 2000 tons of antimony ore from the Chatham mine to San Francisco. Reasonable freight rates will be charged by the American-Yukon Navigation Co. Sacked ore, over 250 tons, will be about $15 per ton.

Juneau

The main adits at the Alaska-Juneau mine will probably be double-tracked, according to J. H. Mackenzie.

According to B. L. Thane of the Gastineau company, development at the Kensington, Berner's bay, 60 miles from Juneau, has shown enough ore to warrant the erection of a 1000-ton mill. The first unit of 500 tons is to be designed by the fall; construction will start in spring.

Ruby

Spring clean-ups in the Ruby district are better than expected. Half of the Selch, Deitz, and Walker dump has yielded $80,000, against $80,000 anticipated for the lot. On Long creek A. Larson has opened gravel yielding $7 per foot. At the end of May the town was short of provisions.

ARIZONA

Cochise County

At the Calumet & Arizona plant two blast, three reverberatory, and twelve roasting furnaces are in blast. Large shipments come from New Mexico.——The Copper Queen smelter is receiving a large tonnage of custom ores at present. Eight blast-furnaces are working.

Under the sliding scale of wages, employees of the Copper Queen and Calumet & Arizona companies will be paid on a 19 to 20c. basis, price of copper. The lowest wage in July will therefore be $1.80, and highest $7.

Gila County

One unit of the Inspiration mill started work on June 29.

Greenlee County

The Shannon Copper Co. has issued a report for 1914. For three months the property was idle, owing to the metal market. The smelter at Clifton treated 154,300 tons of ore from the property at Metcalf, and 28,997 tons from other claims. The yield of metal was 9,003,189 lb. copper, 1295 oz. gold, and 60,603 oz. silver. Net current assets total $249,388, exclusive of Shannon Arizona Railway bonds. Experiments with leaching showed good results on oxide ore and tailing. On March 1, 1915, operations were resumed at full capacity.

Pinal County

Underground mining systems of the Ray Consolidated Copper Co. are described by Lester A. Blackner of Ray in Bulletin 102 of the A. I. M. E. With plans and photographs the paper covers 40 pages. Up to 8000 tons per day has been mined. The main orebody is a disseminated deposit in schist and porphyry formed by secondary enrichment. Most of the ore is chalcocite. The deposit covers 205 acres. It averages 121 ft. thick, is up to 2500 ft. wide, and 5000 ft. long. The capping or overburden of leached iron-stained schist, averages 312 ft. thick. There are about 80,000,000 tons of 2.19% ore available for extraction. Owing to the heavy overburden and the low grade of the ore, caving systems have been devised and

adopted which consist in weakening a block of ore by means of shrinkage stopes or ore-filled rooms. Then after undermining and shattering the remaining pillars the ore is drawn systematically, the capping crushing and settling gradually over it. Throughout all the work at Ray two systems have been used, namely, the sub-level or motor-haulage system, employed in thick uniform blocks of ore; and the hand-tramming system, used in the shallower portions.

Mohave County

Construction of the United Eastern 100-ton mill is to be started within the next two months. The vein opened west of

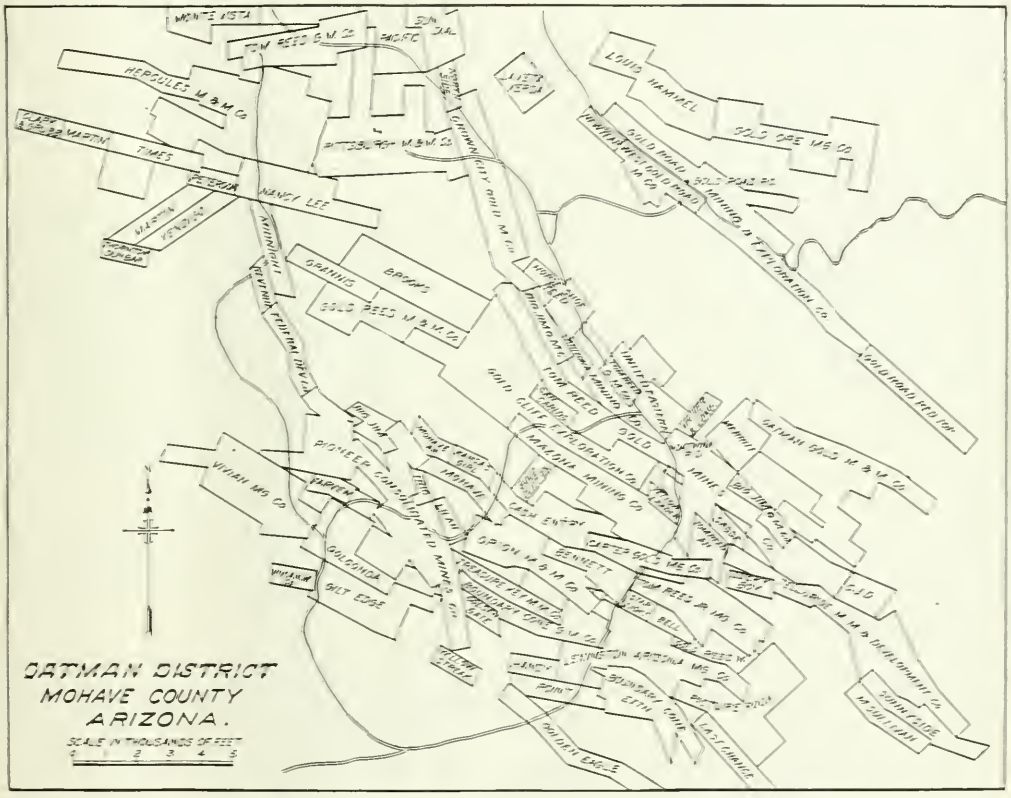
Modoc County

A 10-mile road from Fairport to the Modoc Mines Co.'s property at High Grade is completed. A drainage adit is being driven. A shaft is also to be sunk.

Nevada County

A 100-ft. steel head-frame is being erected at the Brunswick mine. ——Stoking is to be resumed at the Dutch Hill on July 20.

A 100-ft. head-frame is to be erected at the Golden Center mine by R. Hathaway. The new shaft is to be sunk 1000 ft. A 500-gal. Alberger pump has been ordered.



the shaft at 585 ft. is $36.60 per ton over 22 ft. width. It is reported that this company is negotiating for the Telluride property. There seems to be some foundation for this rumor as George Long, director of the United Eastern has consulted with officials of the Telluride.

A custom mill is a possibility for the Oatman district. E. R. Holden and R. Kline have for some time been investigating the reserves of the mines without means of treatment. The plant may be erected on a flat southwest of Oatman. Ores from the district have been tested at Los Angeles.

The Tennessee mine is now 1000 ft. deep. Electric power is to be obtained from Kingman. New machinery is to be ordered.

CALIFORNIA

Amador County

At the Central Eureka the shaft is down 3250 ft. Forty stamps are crushing. One hundred men are employed in charge of J. E. Davis.

Placer County

In the Forest Hill district there is considerable activity in re-opening mines and prospecting. Lessees are also busy.

Plumas County

It is reported that the Plumas Eureka mine at Johnsville, and the Monitor at Gibsonville are to reopened soon.

Shasta County

Farms along Clear creek, near Redding, have been bought by L. Gardella and others of Oroville. The area contains good gravel, and a dredge will be erected there soon.

At Keswick the Noble Electric Steel Co. is making 10 tons of ferro-manganese daily. This is worth $115 per ton in the East. There is 1500 tons of ore awaiting reduction. Eighty men are employed.

Sierra County

A cyanide plant is treating tailing at the Sierra Buena mine at Sierra City. Some of the material is high grade. J. C.

Folsom is in charge.——Although men are busy getting firewood and timber for the Bellevue Gravel Co. at Slate creek, it is not expected that the mine will be worked until after the War. Scotch people control the property.——At the Gardner Point gravel mine near Port Wine, six men are driving a lower adit.——A cross-cut adit nearly 4000 ft. long has been driven in the Sierra Buttes mine. Good quartz has been opened on the hanging wall. About 35,000 tons of tailing awaits treatment at the plant.——At the Young America mine San Francisco people are to treat the 60,000 tons of $1.75 to $2.75 tailing there.

Trinity County

Fifteen hundred acres of placer ground on Trinity river and Coffee creek, from above Carrville to below Trinity Center, have been further optioned till November 1. A large sum is involved if the ground is purchased. E. A. Wiltsee has prospected the area, drilling costing $75,000 so far. More is to be done.

COLORADO

Clear Creek County

In the Waldorf mine near Georgetown the rich stope shows from 18 to 42 in. of ore. The last shipment assayed $118 per ton. It contains a little more lead and less copper than before. Lessees are also doing well.——The Bard Creek company's mill has made its first shipment of 25 tons of lead and copper concentrate.——The Mineral Chief mill is being overhauled. No. 6 level of the mine can supply plenty of ore.——The Capitol mill is working steadily on ore from the numerous lessees, who are doing fairly well. The assayer at the mine, D. Kennedy, is busy testing samples of ore from many prospectors in the region.——Work proceeds as usual at the Virginia City, Key West, and Onondaga mines.

Dolores County

At 404 ft. in the Rico-Wellington mine a 4-ft. vein of zinc carbonate has been cut. Other parts of the mine are looking well.

Gilpin County

The Iron City mill has now a capacity of 80 tons per day. A re-grinding machine is to be installed, increasing the tonnage to 100. It has been said that a good deal of mineral has been lost from Gilpin county mills in the residue run into the creeks. Two weeks ago J. P. Ruth, Jr., had permission to treat slime at the Iron City mill by a flotation process. He expected to recover up to $6 per ton, but of 16 samples the highest was 40c. per ton.——A 10-stamp mill is to be erected at the Two-Forty mine on Pewabic mountain.——Good results are being obtained at the Belden adit, in the Quartz Valley district.

Gunnison County

Lessees at the Doctor mine are about to commence shipping 25 tons of zinc carbonate per day.——The Forest Hill company is working its mine on Trail creek, south side of Taylor park. The 50-ton mill is being re-modeled. There is about 50,000 tons of $9 zinc-gold-silver-copper ore in the mine. L. G. Cavnah is superintendent.——Some mines in Pie Plant gulch will be re-opened this summer.

Montrose County

Mining carnotite and uranium ores is now very quiet, according to O. B. Wilmarth. The Standard Chemical Co. has paid off 200 men and shut-down its plant at Ford. It has tested its new concentrating plant on the San Miguel river.

Ouray County

In May the Camp Bird mill treated 2440 tons of ore. The profit was $23,000.

Saguache County

Sixteen miles southeast of Gunnison is the old town of Iris, which has been quiet for 20 years. Here the Denver City mine is being unwatered and the machinery overhauled. The mine will be examined to see if the zinc and copper veins are worth opening.

San Juan County

In the Silverton district some interesting work is being done at the Flagstaff, Highland Mary, Columbus, Intersection, San Juan Chief, Hermes, Broad Gauge, and Whale mines.

San Miguel County

At Ophir, W. H. Staver, formerly at the Liberty Bell, is preparing for extensive work at the Suffolk and Carbonero mines and mill.——Considerable improvements are to be made by the Tomboy company at its mill this summer.——An addition is being made to the cyanide plant at the Smuggler-Union at Pandora. A transmission-line is being constructed from the upper Sheridan workings of the Smuggler-Union on the Telluride side to the Humboldt workings on the Ouray side of the range.——Ore from the Good Hope and other claims of N. Jurich is to be treated at the Carribeau mill.——There is said to be a good deal of property in Marshall basin available for leasing.

IDAHO

Shoshone County (Coeur d'Alene)

On July 3 the Bunker Hill & Sullivan company paid dividend No. 214. This amounted to $81,750. The total to date is $16,282,500.——At the Frisco mine, at Gem, new crushers, rolls, etc., are to be installed, costing $25,000.

New York people, represented by E. P. Howard, are negotiating for the Rex mine on Nine Mile. F. C. Bailey of Spokane is in charge of the business. The sum of $250,000 has been offered for the property, which is equipped with electric hoist, compressor, pumps, 250-ton mill and other plant. The Rex lead-silver mine is near the Interstate-Callahan zinc mine. The latter distributed $575,000 on July 1. On July 5 the Caledonia company paid 3c. per share, equal to $78,150.

The first shipment of lead-silver concentrate from the Marsh mine in 13 months was sent to Tooele, Utah, on June 29. The shaft is down nearly 1175 ft. from the surface. At the mine 75 men are employed and 15 at the mill.

At the Horst-Powell mine near Kingston, the lessees, A. Page and A. Devlin, have let a contract for a 150-ton mill. About 15,000 tons of ore awaits treatment. On July 1, the Frisco, Green Hill-Cleveland, Morning, and Tamarack and Custer mines were connected with the lines of the Montana Power Co. Previously they got current from the Washington Water Power Co. Competition has lowered rates.

It is rumored that the Hercules company contemplates erecting a smelter at Osburn, as it is not able to make a new contract with the A. S. & R. company.

The Stewart Mining Co. has declared a dividend of 30c. per share, amounting to $371,508. The total for 1915 is $743,017, and $1,919,590 to date.

MICHIGAN

Houghton County (The Copper Country)

On August 2 the Mohawk company will pay $5 per share. The new steel rock-house at No. 5 shaft is well underway. Underground conditions are excellent.——The Franklin mine is milling about 1000 tons per day. Fourteen machines are opening the conglomerate lode.——The Winona is producing about 500 tons per day. Costs are being reduced.——Conglomerate and amygdaloid from the New Arcadian is to be sent to the Franklin mill for a test.

MISSOURI

Jasper County

On June 28 over 1500 miners in the Webb City-Carterville district struck on account of a reduction of wages. The men marched to the mines, demanding that others stop work. There was no violence shown. The cut in wages is from 25 to 50c. per day, and 1½c. per can for shovelers.

Webb City miners last week tried to induce Joplin men to

strike. A branch of the American Metal Miners' Union is to be formed at Joplin.

On July 1 a conference between miners and mine operators agreed on a new scale, based on $80 per ton for zinc blende. No man underground is to receive less than $4 per shift. Following is the scale agreed on: machine men, $4.50; machine men's helpers, $4; mulers, trimmers, and trimmers' helpers, $4; powder men, $5.50; powder men's helpers, $5; tub hookers, $5; hoist men, $5.50; jig men, $5.50; jig men's helpers, $4; sludge men, $4; screen men, $3.50; motor men, $5.50; brakemen, $4.50. Shovelers are to be paid at the rate of 1c. per each 100 lb. of 'dirt' handled. The price of a 1000 lb. can would be 10c., for 1250 lb. 12½c., and for 1650 lb. 16½cents.

At the U. L. Young tracts 7000 ft. of drilling is to be done. Two holes have cut 'jack' at 116 to 125 feet.

MONTANA

Fergus County

(Special Correspondence.)—A large amount of good-grade gold ore is opened in the claims of Frank Finlaw and Henry Allister on the north side of the Judith mountains near New Year. They have done over 4000 ft. of work. Cyaniding will suit the ore.

The Gold Acres Mining Co., adjoining the New Year mine, is said to have an outcrop of mineralized formation for 2300 ft. on its claims. Samples averaged $7.18 per ton. Lime partings will reduce this average somewhat. Condemnation proceedings have been successfully concluded by which the company obtains five acres adjoining its property for use as a dump and building-site. Two shifts are now working on a 1600-ft. adit, together with cross-cuts and a raise which, it is hoped, will expose the deposit so that a better idea of the tonnage and value of the ore can be obtained.

Three prospectors are re-working the placers in Alpine gulch where gold was first discovered in the Judith mountains 35 years ago. The unusually heavy rains have supplied abundant water. The men claim to be making $7 or $8 per day.

Lewistown, June 28.

Silverbow County

Part of the Anaconda company's Washoe plant was disabled last week, and the mines were closed for a time.——At 2500 ft. in the Davis-Daly the shoot has been opened for 150 ft. It is 6 ft. wide, containing from 5 to 7% copper.

NEVADA

'Ground-Water in Southeastern Nevada' is the title of Water-Supply Paper 365 of the U. S. Geological Survey, by Everett Carpenter. The area covered in the report comprises 6000 square miles in Clark, 8500 in Lincoln, 300 in White Pine, and 2000 in Nye counties. Pioche, Caliente, Lund, Moapa, and Las Vegas are in the territory. This lies in two drainage provinces, the Great Basin and Colorado River basin. The most characteristic topographic features consist of a series of parallel north-south ranges, and intervening broad debris-filled valleys. Pine and other trees to native grasses grow from the mountains down. Rainfall is from 3.42 to 11.99 in., the latter at Pioche. The report discusses the occurrence of ground-water, springs, artesian water, quality of water, watering places on routes of travel, and the Railroad Valley district.

Clark County

The Goodsprings district is benefiting from the high price of spelter.——It is reported that the A. S. & R. Co. has purchased the Whale property.——The Azalea, Mohile, Bill Nye, Sultan, New Year, and others are shipping ore. A mill, using a Plumb jig, is working at the Frederickson.——Rich silver ore has been opened in the Akron.

Esmeralda County

The estimated production of the Goldfield Consolidated Mines Co. during June is as follows: ore mined, 32,206 tons; gross extraction, $310,000; operating expenses, $169,000; net realization, $141,000.

Humboldt County

(Special Correspondence.)—The California Ore Testing Co., San Francisco, has completed tests on ore from the Nevada Packard mine. A high recovery was obtained by all-sliming and direct cyaniding. As much as 90% was obtained in the tube-mill circuit during grinding, and a total of 98% after 24 hours' treatment. The tests were made on higher-grade ore than is expected in actual mining, yet a 96% extraction is anticipated on $15 to $20 ore. Silver is the principal metal. The mill is to be one of the most up-to-date in Nevada. It will have a capacity of 100 tons per 24 hours, passing 200 mesh. There will be a gyratory-crusher, rolls, trommel-screen, steel-ore storage-tank, 5 by 6-ft. pebble-mill, Dorr classifier, 6 by 12-ft. pebble-mill, Dorr cyanide equipment, Oliver filter, and zinc-dust precipitation. K. Freitag is metallurgist and constructing engineer.

Rochester, June 30.

At the Nevada Packard there is about 8000 tons of $14 to $22 ore on the dumps. Thirty-five men are employed. Underground developments are excellent.

The new 12-drill motor-driven compressor at the portal of the Friedman adit of the Rochester Mines Co. is working. The adit is in 300 ft. The refinery at the mill is complete. Grading for the railway is finished to upper Rochester. On July 2 bullion worth $40,000 was sent to Lovelock.

Following are the most important items from Willard: Lessees at the Sheepherder's Dream recovered gold worth $425 from 180 lb. of ore. Prospects are considered good at depth. There is 25 tons of $100 ore waiting shipment.——A. Gordon, of Minneapolis, has an option on the Bull Dog and Banjo claims, next to the above mentioned mine, for about $10,000. ——At the Honey Bee a contract has been let for 100 ft. of driving.——Cross-cutting is under way at 50 ft. in the Oddie-Malley-Cole lease.——The Borland-Healey lease adit is in 65 ft.—— Frost and Cahill have a wide vein of rich ore.——Work at the Paulson and Hunter and Grey leases is satisfactory.

Lincoln County

On August 2 the Prince Consolidated will distribute 2½c. per share, amounting to $25,000. Another dividend of equal amount was paid last week. Drilling has revealed encouraging prospects.

Lyon County

Near Yerington is the Pittsburg-Dolores gold mine, one of the leading producers of the district. There is about five years' ore opened in the mine for the mill and cyanide plant of 70 to 80-ton capacity. E. J. Schrader is manager, J. Perry mine superintendent, and C. R. Olsen mill superintendent.

Nye County

Following are the most interesting events at Tonopah last week:

Six companies and lessees produced 10,100 tons of ore worth $207,760.——The Tonopah company dispatched bullion worth $42,000.——On August 2 the Jim Butler company will pay 10c. per share, the first, amounting to $171,802. The balance on hand is about three times this sum. Development continues to be very satisfactory.——The Tonopah Midway shaft is down 1280 ft.——At 1350 ft. the Extension has cut the foot-wall vein. It is 5 ft. wide of good grade.——The Belmont's report for the quarter ended May 31 shows that the revenue was $632,822, and net profit $260,973. Cash, loans, and silver are worth $1,529,-891. Dividend No. 24, of 12½c. per share, equal to $187,500 has been paid. The total is $7,455,510.

UTAH

Juab County

Ore shipments from companies and lessees in the Tintic district last week totaled 169 cars.——At the Lower Mammoth the 1000-ft. level is now producing $15 silver-copper ore. Ten blocks of ground in the mine are worked by lessees. One lessee at 1500 ft. shipped a car of 40% zinc ore.——A 100-ton capacity

ore-house has been completed at the Chief Consolidated. Twenty blocks are being mined by lessees. The total output last week was 20 cars.——Motor-driven pumps at 1600-ft at the Gemini are ready for work.

Salt Lake County

Considerable activity continues in the Big and Little Cottonwood districts. Genuine prospecting and development is noticeable.——At the Columbus Extension the drift to the Toledo fissure is out 180 ft. in heavily mineralized formation. Ten men are employed.——At the Alta Con. machine-drills are now in use. Air comes from the Wasatch compressing plant.——In the Sells, drifts are in the quartzite-limestone contact. The Alpha and Skipper fissures are expected at a vertical depth of 1000 ft. Machine-drills are working here.——Also at the Emma copper mine in limestone shale.——Forty-five teams are hauling 100 tons of ore per day from the Cardiff. The output is to be increased. Fifty men are working at the mine. Electric haulage is to be used.——The Cedar-Talisman has shipped some lead ore and will also market zinc ore.——The Price company has started its adit into Montreal hill. Three units of the Ohio Copper mill are treating over 2400 tons of ore per day. Concentrate is sent to the Garfield smelter. Mining is cheaply done by the caving system, 3,056,000 tons having been extracted since December 1909. Over 200 men are employed.

The Utah Copper Co. is employing 1590 men at the mine, 250 on the railroad, and 1500 in the mills, a total of 3340. The payroll is now over $200,000 per month. The scale of operation is greatly benefiting thousands of other Utah people.

Summit County

Park City mines last week shipped 2917 tons of ore.——Fourteen sets of lessees are busy at the Old Daly, mostly at 800 ft.——On the 500-ft. level of the American Flag mine 30 in. of 2 oz. gold and 30-oz. silver ore has been cut. Ore from this property goes to the Park City Mills plant.

The Silver King Consolidated has issued an interim report along with No. 8 dividend. Early in 1915 the output was only 35 tons daily. From March to June bad roads prevented this quantity being shipped. Everything now is in order for a large output. Higher lead prices have increased profits. Ore between No. 3 and 4 raises occurs as a wedge not less than 150 ft. long and 34 ft. high. Prospects at 1800 ft. are excellent.

Washington County

The population of Goldstrike is nearly 200.——A three-stamp mill is to be erected at the Bee Bee mine.——The Goldstrike Mining & Leasing Co. has a plant of similar capacity. A visiting engineer is reported to have said regarding the ore of Goldstrike, "Go down and you have got it."——A 70-ton mill is to be built for the Goldstrike Consolidated Mining Company.

WASHINGTON

Kittitas County

(Special Correspondence.)—The owner of the Golden Rule placer claim, H. D. Harkness, last week recovered about 11 oz. gold. The largest piece was worth $18.25.——Powers and Sugars have taken a five-year lease on the Trilby placer claim. The drainage adit is in about 200 ft. They expect to cut bedrock in the next 40 ft. The upper part of the claim has been piped off for about 300 ft., and about $11,000 was extracted. The present lessees will open the remainder of the ground, the channel is narrow, and the ground being cement-gravel, stands well.——Craven and Renney are starting to open their placer claims on Lion's gulch.——A. E. Norcross has leased the gravel dumps of the Enekel mine. He is now ground-sluicing.——J. E. Powles is also sluicing the dumps of the Discovery claim.——Johnson and Anderson have started work at the Bigney mine. They expect to cut the north run of Williams Creek vein within two months.——B. Kilsen, of the Hope quartz mine, took out some fine specimen ore in the shaft recently. His arrastra is steadily grinding a good grade of ore.——George Marshall of Vancouver, B. C., has charge of men at the Cougar mine.——Thomas Meagher and others are prospecting Nanem creek on Table mountain. Near the summit there is a flat of over 200 acres; almost anywhere there fine gold can be panned. There is plenty of black sand which has made it difficult to save the gold in the sluice-boxes. They are prospecting the ground carefully, and may devise a scheme to work it on a large scale.——It is likely that the state highway will be built through Liberty. This will give mining an impetus. It will give a first-class road up the Swank and over the Blewitt pass.

Liberty, June 26.

Stevens County

A bid of $128,000 for the Copper King mine at Chewelah, by Danson, Williams, and Danson of Spokane, in behalf of the J. Grier Long estate, H. H. Herbert and A. F. McClaine of Spokane, was rejected on June 25 by Judge W. H. Jackson in the superior court at Colville, and the bid of $125,000 presented by J. W. Douglas, of Orient, associated with Volney Williamson of Spokane, was ordered accepted.

CANADA

Alberta

In two volumes issued by the Department of Mines at Ottawa, the petroleum and natural gas resources of Canada are discussed by Frederick G. Clapp and others. No. 1, with illustrations and maps, covers 378 pages. The production of the Dominion in 1912 was 243,614 bbl. of 35 gal. each, worth $1.42 per bbl. The output of natural gas in that year was approximately 15,286,803,000 cu. ft. valued at $2,362,700. Ontario yielded 12,529,463,000 and Alberta 2,583,437,000 cu. ft.

British Columbia

After several months' shut-down the Standard silver-lead mine at Silverton is again in full operation. The monthly output of concentrate is between 1200 and 1500 tons. The company is shipping this to the Consolidated company's smelter at Trail, a new contract having recently been made.

Six cars of zinc concentrate sent to Bartlesville, Oklahoma, from the Rambler-Cariboo mill in June netted $13,000. Other cars are not settled yet. On account of the expiration of the zinc smelting contract zinc concentrate is being stored at the mill at Three Forks.

Ontario

On July 20 La Rose Consolidated pays $74,931. Since 1908 the total distribution has been $5,322,189.

The Foster mine at Giroux lake has been re-opened after three months' shut-down. The Glen Lake Mining Co. controls the property.

MEXICO

El Oro

Esperanza, Limited, the English company controlling the Esperanza Mining Co., operating at El Oro, has issued its report for 1914. The former's profit was $153,000. Out of this, $101,000 was paid as dividend No. 57 on March 26, 1915. The balance carried forward to 1915 is $20,200, against $14,000 brought forward from 1913 to 1914. Dividends to date amount to $12,000,000.

Owing to the revolution in Mexico, milling ceased on April 21, 1914. In August work was resumed, continuing on a small scale until the end of February of the current year, when treatment was suspended. There were then no facilities for transport of supplies or bullion. The property has suffered no physical damage.

Development on 14 levels totaled 13,277 ft. Of this, 4918 ft. was on the San Rafael vein, 3353 ft. on West vein No. 1, 1130 ft. on West vein A, and 3616 ft. on San Carlos vein. The total was an increase of 130 ft. over that of 1913. Openings to date are 155,467 ft. Much of last year's work resulted in further opening orebodies and old filling. A 4-ton Jeffrey electric locomotive was installed on No. 2 level. Reserves are estim-

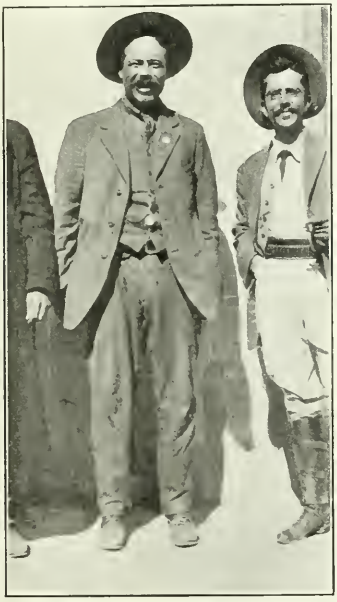
ated at 148,254 tons, containing a profit of $446,000. This does not include old stope-filling or 200,000 tons of tailing on the dump. Ventilation in the south end of the mine was much improved.

The mill treated 120,975 tons of mine ore, an increase of 35,132 tons, and 45,237 tons of old tailing, against 121,438 in 1913. Bullion and concentrate recovered was worth $1,039,698. The working profit was $402,426. Deducting special adjustments, exchange being $85,171, the net profit was $319,967. Dividend declared amounted to $157,500. The balance at the end of the year was $465,757, against $303,289 at the beginning.

The output to date is 2,063,252 metric tons yielding ₱71,289,157.

Guanajuato

At the end of June the three principal mining companies operating at Guanajuato had to shut-down owing to the lack of necessary supplies. The pumps will be kept going, and a few men will be retained at each mine to protect roadways and so forth. All the bullion extracted since the beginning of April has been allowed to accumulate, together with the concentrate. The Carranza forces have held Guanajuato for nearly three



FRANCISCO VILLA AND COLONEL MEDINA.

months, with short intervals of occupation by Villa's troops. Recent decrees of Carranza impose heavy taxes, retroactive to November, but as his authority is precarious, it is hoped that they will not be collected.

Hidalgo

In May the Santa Gertrudis mill treated 13,670 tons of ore with an estimated profit of $24,000.

Sonora

At Nacozari the Moctezuma continues to operate at full capacity, in spite of the railway being closed. A large tonnage of copper concentrate is accumulating. It is possible that the line may be re-opened in about two weeks. Four bridges were burned.

Work has been resumed at the Democrata mine and smelter near Cananea. About 350 men are employed. H. McKey is general manager.

PERSONAL

H. C. Bellinger is at New York.

Bernard H. Sanders has gone to Brazil.

Edgar Bonds is at Tarkwa, West Africa.

Hennen Jennings is expected at Berkeley.

Edward H. Watson is on his way to the Malay States.

C. H. Munro has returned from Colombia to New York.

J. K. Beasley has returned to England from South Africa.

J. G. Lawn, consulting engineer to Barnato Bros., is on a visit to London.

J. K. Turner, of Goldfield, has been inspecting the prospects at Willard, Nevada.

Andrew C. Lawson, O. H. Hershey, and Fred Searles have returned from Juneau.

Milnor Roberts has been visiting on the Comstock lode and is now in San Francisco.

Mansfield Merriman is the new president of the American Society for Testing Materials.

A. H. Lawry, superintendent of the Montana-Tonopah mine, has gone for a trip to Australia.

William J. Priestley, Jr., has been appointed superintend- of the Comet mine, at Basin, Montana.

J. B. Tyrrell has been elected president of the geological section of the Royal Society of Canada.

J. V. N. Dorr will spend most of the month of July in Colorado. During August he will be in San Francisco.

J. Norman Bulkley has been appointed consulting mechanical and electrical engineer to the Canadian Mining & Finance Co., Ltd.

George I. Adams is now professor of geology at Peking University. Franklin R. Barker has been appointed as the successor to Mr. Adams at Pei Yang University, Tientsin, China.

F. Fukeda, chief metallurgist of the Ikuno mine of the Mitsubishi company of Japan and Messrs. K. Hishida and S. Negishi, of the Kuhara Mining Co., were in San Francisco this week and have left for a tour through the principal metallurgical plants of the United States.

Albert Burch has resigned as consulting engineer to the Goldfield Consolidated Mines Co. and as vice-president and general manager to the Aurora Consolidated Mines Co., to take effect at the end of this month. He intends to devote more time to general engineering practice.

Obituary

On June 25, Scott Eldridge, engineer of the Kerr Lake mine and W. B. Foote, a mining investor of Geneva, New York, who was visiting the mine, were instantly killed by a blast that went off at the 250-ft. level when they were in the stope at the 140-ft. level.

George B. Crooks died at San Francisco on July 4. For many years he was connected with John Taylor & Co., the first firm to engage in the sale of assaying supplies on the Pacific coast, and later with its successor, the Braun-Knecht-Heimann Co. He was well known to mining men throughout the West and leaves many friends.

Schools and Societies

The International Gas Congress will meet in San Francisco during the week beginning September 27.

THE MARKET PLACE

Weekly Summary of Metal Prices and Notes on the Markets.

Metal Prices

San Francisco, July 8.

Antimony	.35 —35¾
Electrolytic copper	20½—20¾
Pig lead	6.00— 6.95
Quicksilver (per flask)	$95
Spelter	.22 —22¼
Tin	.41 —42½
Zinc-dust, 100-kg. zinc-lined cases	30

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, July 8.—Copper is dull, the market still waiting; lead is quiet but firm; spelter is very firm, with a steady demand for nearby delivery.

COPPER

Prices of electrolytic in New York, in cents per pound.

Exports during the week ended June 26 totaled 6,955,353 lb., valued at $1,208,775. Of this, 3,815,037 lb. went to England, 1,120,263 lb. to Russia (Europe), and 1,033,000 lb. to Italy. Imports of all kinds of copper amounted to 12,418,070 lb., worth $1,358,262.

The estimated output of Michigan in June was 27,000,000 lb. The White Pine contributed about 730,000 lb. of 60% mineral.

The Anaconda yield in June was 22,100,000 pounds.

On June 29 the first unit of the Inspiration mill started work.

During the last two weeks of June the Braden mine, Chile, produced 1,400,000 lb. from 47,079 tons of 2.09% ore.

In May outputs were: Chino, 6,442,000; Nevada Con., 5,271,756; Ray, 5,167,717; and Utah, 14,053,765 pounds

The following dividends are to be paid about July 1:

	Per share.	Amount.
Ahmeek	$10.00	$ 500,000
Anaconda	0.50	2,311,250
Chino	0.75	652,500
Nevada Consolidated	0.375	750,000
North Butte	0.10	172,000
Old Dominion	1.00	293,353
Osceola	3.00	288,450
Quincy	2.00	220,000
Ray Consolidated	0.375	547,042
Utah Copper	1.00	1,625,000
Total		$7,359,595

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date		Average week ending

Weakness in silver continues. In London the market has been lifeless, daily operations small, and interest taken by buyers negligible. Offerings from the United States have been restricted in amount. India and China have not given strength. Exports from London to those countries up to June 16 were approximately 11,000,000 oz. less than in that period of 1914. Stocks in London are about 16,000,000 oz. On July 3 a shipment of 250,000 oz. went to China from San Francisco. According to the last quarterly report of the Tonopah Belmont company, it had silver stored worth $837,455, say, 1,674,910 ounces.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

Production of zinc and lead ores from the Missouri-Kansas-Oklahoma region for the first half of 1915 was as follows:

Ore.	Tons.	Value.
Zinc-blende	138,145	$9,772,546
Calamine	11,235	479,964
Lead	21,377	1,101,144

Some Joplin people predict that zinc-blende will advance to $150 per ton by October 1, and the year's total at $25,000,000.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending

On July 7 tin was quoted quiet at 38.75 to 39.25 cents.

Eastern Metal Market

New York, July 2.

Following its recent collapse, spelter strengthened. In the last week it gained 4c., and it is at present firm at about 22c. New York prompt delivery. The largest lead interest has held to 5.75c., New York, for several days. The quotation of others have advanced, and all are now more nearly on an equal basis. Copper is strong, so far as the producers are concerned, as they anticipate a renewal of war buying, but second-hands are offering concessions. In tin, the market has been rather uneventful, the principal feature being the June statistics which showed deliveries of 3900 tons in June. Antimony is strong. Aluminum is scarce for early delivery and its price is maintained.

General business is showing a decided betterment. Great encouragement is drawn from the fact that the improvement is felt outside of the circles which are profiting from war business. The steel mills are steadily growing busier; higher prices are being asked, and the betterment must radiate in all directions. All know that the steel business has been called a 'barometer of trade.' More large war orders are in prospect.

COPPER

For several days the market has been characterized by quiet amounting to dullness, but the quotations of first-hands have continued firm. The presence of several large inquiries from manufacturers of munitions of war has sustained the belief that a buying movement of good-sized proportions will start soon, probably after the Fourth of July holiday. The producers have therefore adhered to their quotations of 20.25 to 20.50c., 30 days, delivered, for electrolytic. Second-hands have offered metal at concessions, particularly in the past two or three days, but it is understood, generally, that not a great deal of re-sale copper is available. For July delivery second-hands might accept as low as 19.62½c., but most of them continue to quote 20c. for spot metal, with the quotation nominal. In Lake there has been a slight show of interest, and occasional carloads have been available at concessions. Quotations range from 20.50c. for common grades to 22.50c. for choice brands. The exports in June totaled 15,751 tons, compared with 28,193 tons in May.

LEAD

Since the last report lead has gained in strength and there has been a steady drawing together of the prices quoted by independent producers and those of the A. S. & R. Co. On June 24, 25, 26, and 28 the independents were quoting 5.50c., New York, while on each of those days the largest interest quoted 5.75c., New York. The re-sale metal which was offered at low prices has been steadily disappearing under buying at the concessions offered, and it is intimated that there is some hidden influence behind its absorption. However that may be, the quotations in the open-market advanced June 29 to 5.60c. and June 30 to 5.70c., the A. S. & R. Co. continuing to quote 5.75c. on both days. Its quotation is still unchanged. That there is still considerable irregularity in the market is evidenced by the fact that a sale was made June 28 at slightly over 5.75c., New York. The London market is so far below New York parity that it is difficult to see how export sales can be made, unless producers are willing to take on export business less than the domestic price. The London quotation yesterday was £25 15s. per ton. The June exports totaled 6606 tons.

SPELTER

On June 25 there was a sharp advance in spelter, some of the producers asking on that day 20 to 20.50c., or 2c. more than had been ruling for prompt metal. For some days the market had been practically dormant at 18 to 18.50c. The advance, and a further upward trend which followed, were attributed to a betterment in the demand and to labor troubles in the Webb City-Carterville ore district, although it is not believed that the trouble will be of long duration. With the price of spelter where it is, it is thought highly probable that the miners will be granted the increase in wages they demand. On June 29 the London market advanced £7 10s. per ton, which was an additional strengthening influence on this market. By June 30, 22c. was asked for prime Western, prompt delivery. Brass-mill specials were quoted at 28 to 30c., and for very choice brands such as Bertha and Horsehead, as much as 40c. was offered. The July and August supply of ordinary grades is not over plentiful. In the early part of the last week in June future deliveries could have been had at 16c.; later they advanced to over 20c. The recent decline in the spelter market, from 28 to 18c., caused the quotations for galvanized sheets to become easier. The present quotation for No. 28 gauge is 4.50c., mill, but the situation is rendered doubtful by the new upward turn of spelter prices. The cables report that the galvanizing trade of England is in an unsettled condition because of the scarcity of zinc, and because of the Government's statement that it may take over the control of the entire supply. The exports in June totaled 2746 tons. The highest New York price in June was 28c., and the lowest 18c. The highest price in London was £110 and the lowest £87 10s. per ton.

TIN

Trading has been light and the trend of prices has been downward. On June 25 the spot price touched 41.25c., having advanced from 41c. quoted the previous day, but the quotation dropped on June 28 to 40.50c., on 29th to 40c., and on 30th to 39.37½c. On July 1, the following flurry of buying of future positions the market went to 39.75c. On one or two days in the week there was fair business in spot metal and early shipments from London, but no really large quantities changed hands on any one day. Quotations are pursuing a more even course than is usual with tin for the reason that the restrictions placed on trading by Great Britain have practically eliminated speculation. The necessity of giving guarantees specifying the ultimate consumers of the metal is a hindrance to free buying and selling. The deliveries into consumption in June reached the excellent total of 3900 tons, 900 of which arrived at Pacific ports, destined for the East. The total of deliveries for 6 months, 21,575 tons, shows a decrease of 1525 tons compared with the same period last year. Shipments from the Straits in June, 6665 tons, were 795 tons larger than for the same month last year. In six months Straits shipments were 862 tons larger than in the same period last year. Australia shipped 141 tons in June, compared with 153 tons in May. The stocks, including on dock and landing, July 1, totaled 2319 tons, and there was afloat on that day 7410 tons. The total visible supply June 30 was 15,927 tons, against 16,027 tons June 30, 1914.

ANTIMONY

Some slight pressure to sell stock on hand led to a softening of prices for Chinese and Japanese antimony in the week, but the easiness was only temporary. Spot metal sold at 36.25 to 36.50c. duty paid. The general quotations range from 36 to 37c. On one or two days there was fair buying, but the needs of ammunition makers seem to be supplied for the present.

ALUMINUM

Prompt metal is scarce and quotations are firm at 31 to 33 cents. Aluminum consumption in the United States in 1914 amounted to 79,129,000 lb. Bauxite production was 219,318 tons, worth $1,069,194.

MINING DECISIONS

Assessment Work—Prima Facie Proof of

The location of a junior mining claim has the burden of proving that the senior conflicting claim was forfeited by failure to do the required annual assessment work. Where it appears that an affidavit by the senior claimant was of record to the effect that the work had been done and there was no proof to the contrary, the Court must presume, under Civil Code Section 1426m, that the work has been done. Where a corporation owns the claim in question a stockholder therein may perform the work and it will inure to the benefit of the corporation.

Musser *v.* Fitting (California), 148 Pacific, 536. March 13 1915.

Mining Corporation—Sale Set Aside

Where the directors of a non-operating mining corporation sold the properties of the Company to the Anaconda Copper Mining Co., for a stock consideration and assumption of outstanding debts by the latter company, and it did not affirmatively appear that the consideration was wholly adequate, upon the suit of minority stockholders a re-sale was ordered to be made in the open market, with the proviso that if no better price could be obtained, the first sale might stand, and the minority stockholders be paid a cash consideration equivalent to the market value of their pro rata of the Anaconda stock.

Geddes *v.* Anaconda Copper Mining Co. (Montana), 222 Federal, 129. May 1, 1915.

The mine in question was the Alice at Butte. The decision was published in the Press of May 8.

Oil and Gas Lease—Gas Well Defined

Where the lessor under an oil and gas lease had permitted his lessee to operate a certain well for seven years as an oil-well, and during that period paid no attention to the small amount of gas which was produced from it in non-commercial quantity, he could not at the end of that period, when the oil production commenced to decrease, recover from the lessee the minimum gas rentals provided for in the lease. A 'gas-well' was defined as a "well having such a pressure and volume of gas, and considered with respect to its location, its proximity to the market, as could be operated profitably, and the gas utilized either on the leased premises or disposed of commercially to others."

Prichard *v.* Freeland Oil Co. (West Virginia), 84 Southeastern, 945. April 20. 1915.

Placer Claim—Forfeiture Denied

A placer claim was located by plaintiff in 1905. Little work done on it until 1913, although the defendant moved into a house on the claim in 1910. In 1913, extensive dredging operations having taken place in the vicinity, and the land within the claim having been known to contain gravel deposits, plaintiff expended time and labor to the value of $135 in clearing off brush on the claim so as to prepare it for dredging. Early in 1914 defendant filed a location notice claiming the ground as having been forfeited by plaintiff for non-performance of assessment work. Held: that whatever may or may not have been done in the way of assessment work during the years intervening between 1905 and 1913 by plaintiff, the work done during the latter year and before defendant's attempted re-location intervened, operated to prevent a forfeiture and plaintiff's claim was held valid.

Richen *v.* Davis (Oregon), 148 Pacific 1130. May 25, 1915.

Lathes: Their Construction and Operation. By George W. Burley. Scott, Greenwood, & Son, London and D. Van Nostrand Co., New York. P. 228. Ill., index. For Sale by Mining and Scientific Press, San Francisco. Price, $1.25.

The lathe is one of the most important of modern machines, for on it depends the successful construction of most other machinery. After a brief, historical review of the subject, the present volume takes up the different classes of modern lathes, namely, hand-turning, engine, turret, vertical and special lathes. The general characteristics and field of use of the different types are considered and there are a number of illustrations showing the principal kinds of each type of lathe. A chapter is devoted to such lathe accessories as chucks, mandrels, etc., and their uses explained. The subject of lathe tools is discussed in connection with tool steels and some space is also given to the questions of feed and cutting speed. Another chapter is devoted to lathe-work in general. The appendix contains tables of gear-wheel combinations for cutting different screw-threads. While the treatment throughout is entirely practical, the underlying principles involved are considered, and the book will be of value to the student as well as to the practical machinist.

New Machines and Devices

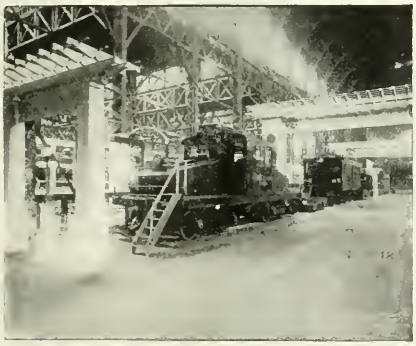
Information based on letters and catalogues from manufacturers.

Electricity at the Exposition

Prominently connected with the Panama-Pacific Exposition is the General Electric Co. of Schenectady, New York. Besides its own extensive exhibits in the Palace of Transportation, the brilliant lighting effect is the work of this company's engineers. These do not cover the G. E. displays, as a complete electrically-operated bungalow, termed the 'Home Electrical,' is open for inspection in the Palace of Manufactures. Many G. E. motors were employed during the construction of the Exposition buildings. In the 'Zone' or amusement part of the Fair, G. E. products are largely used.

In the large artistically arranged court-yard of the Home Electrical the company shows a 'Mazda' service research laboratory for the well-known incandescent lamp. Raw materials, and parts in process of manufacture, explain construction of the lamp. Nearby is the commercial incandescent lamp exhibit, which includes from the 'grain of wheat' size to the large 1000-watt gas-filled lamps. All kinds of other apparatus are displayed. Nearby again is one of the Exposition substations, using G. E. products. It consists of a 1000-kw. motor-generator set, 250-kw. balance set, transformers, switchboard, etc.

The main exhibit of the company covers 9000 sq. ft. in the



GENERAL ELECTRIC LOCOMOTIVES.

Palace of Transportation. Of this, 7735 sq. ft. is for apparatus display, the balance for trackage. The show is ornamental in design. The exhibit comprises electric locomotives for various classes of service from underground mine haulage to heavy steam railroad electrification; railway motors and all kinds of apparatus for electric railways, representing the latest developments in modern city and interurban electric service; signal accessory electric devices; electric apparatus and equipment for railway shops; electric illumination for cars, shops, etc. All essential parts of electric traction are demonstrated in operation.

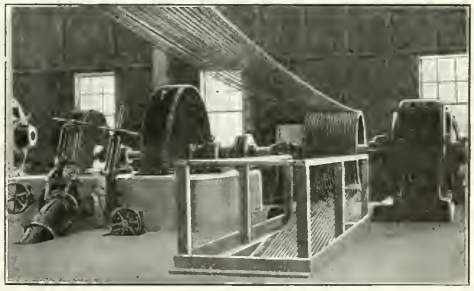
An impressive exhibit is the electric locomotives, of which five different types are included. The Butte, Anaconda & Pacific locomotive, occupying the central space of the group, is one of four units that have recently been built for this road, and is a duplicate of the original 17 units put into service in 1913. These are the first direct current electric locomotives for operation at 2400 volts ever built. Each unit weighs 80 tons. Two are, however, coupled together for freight service to form a locomotive weighing 160 tons. The combination freight locomotives are hauling main line trains of 4600 tons at a speed of 16 miles per hour against the ruling grade of 0.3%, and at 21 miles per hour on level tangent track. Over 5,000,000 tons of ore and supplies are carried annually on this road.

The electric mining locomotives consist of a large 20-ton trolley type equipped with three motors and a six-ton combination trolley and storage battery locomotive equipped with two motors, all of the commutating pole type. The latter is so arranged that it may be operated on the storage batteries for gathering beyond the point where the trolley wire extends, the batteries being re-charged from a small charging set mounted in the locomotive and operating on the trolley voltage, thus obviating the necessity of laying up the locomotive while charging or changing the battery.

Mining men will find the above traction apparatus of great interest. They will also see many other electrical products in the G. E. exhibit, too numerous to mention here. *The General Electric Review* for June especially covers the firm's exhibits, also the use of electricity in many industries.

Combined Water-Wheel and Motor-Drive

At the Snowstorm mine, Larson, Idaho, an air-compressor had been in use for a number of years, driven by an impulse water-wheel, the buckets of which were attached to the rim of what served as the flywheel. The supply of water was limited,



COMBINED WATER-WHEEL AND MOTOR-DRIVE.

so that at certain seasons it was almost impossible to operate the compressor, according to A. O. Gates. Electric-power became available from a reliable supply. It was decided to install such equipment as would allow the utilization of all the water-supply, and keep the compressor supplying the maximum demands of the mine.

Two water-wheels and one motor, mounted on shafts having the same centre-line, connected together by a flexible-coupling, supply the power to drive the compressor. The smaller water-wheel is designed to operate at the full speed of the motor, the two to drive together, the motor delivering the excess power over that available from the water-supply. This varies, of course, with different seasons of the year. When there is less demand for air from the mine the water is diverted to the larger impulse-wheel, which runs at about the same peripheral speed as the smaller wheel (water having same spouting ve-

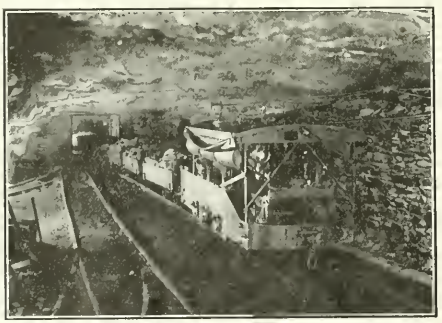
locity), but at about two-thirds the relative speed, the compressor now delivering a proportionate amount of air, and taking less power. The motor is disconnected from the power-line, but turns with the wheels. Thus, by the use of two wheels, the most efficient conditions for water-wheels are maintained during varying loads, the amount of peak electricity being kept at a minimum. On the compressor, the old wheel was replaced with a split cast-iron rope fly-wheel with 18 grooves for 1¾-in. rope. The compressor runs at 90 to 95 r.p.m. at full speed, and about 60 r.p.m. at reduced speed. About 350 hp. is required by the compressor at full speed. As the motor is rated at 275 hp., it must run at an overload during those rare intervals when no water is available. This obtains a better efficiency from the motor at the partial loads of normal operation.

In this plant is another similar compressor, but driven by means of a belt from a single motor. The rope and belt drives of same capacity side by side, offer some interesting comparisons. One of these is the practical noiselessness of the ropes, while there is a hum and crackle to the belt. The rope drive is cheaper in its first installation, and the cost of maintenance is much less than that of belt.

New Gasoline Locomotive

To meet the demand for cheaper transportation in mining and the allied industries, various types of locomotives have been developed. These are propelled by steam, electricity, and gasoline. Among the self-contained units that have resulted is the 'Plymouth' gasoline industrial locomotive. The cost of operating the gasoline locomotive is claimed to be one of the numerous advantages of this type of machine.

The model N locomotive shown in the accompanying photograph is equipped with a four-cylinder 23-34-hp. motor. The



A PLYMOUTH LOCOMOTIVE UNDERGROUND.

cylinders are 3½ in. bore, with 5-in. stroke. They are made from a special grade of reverberatory-furnace iron. The water-jacket heads are cast separately, and being retained by screws are easily removed.

The crank-case is an aluminum casting and the oil-pan is of pressed steel. The enclosed valves are mechanically operated on one side of the motor by a single cam-shaft. The inlet and exhaust-valves are interchangeable. The pistons are of the same grade of metal as used in the cylinders, and are fitted with three diagonally split-concentric expansion-rings.

The connecting rods are of I-beam construction. The cam-shaft is drop-forged, as is also the crank-shaft. The bearings are of nickel babbitt. A thermo-syphon cooling system and a combination of force-feed and splash-system of oiling is employed. A Bosch magneto is used for ignition. Hyatt flexible roller-bearings and friction-drive transmission are parts of the equipment. A heavy two-piece cast-iron frame adds tractive force to the locomotive and makes a very rigid frame.

The shafts and axles are of high carbon steel. The ordinary speeds of the locomotive are from 3 to 10 miles an hour. The draw-bar pull for the 3-ton locomotive is 1200 lb., at 5 miles an hour. The hauling capacity on the level is 27 tons, or 7 tons on a 4% grade. Every part of the locomotive is accessible, and any part easily removed when necessary.

Commercial Paragraphs

A 48-in. Symons disc-crusher, made by CHALMERS & WILLIAMS of Chicago Heights, has been installed by the Garfield Smelting Co., Garfield, Utah.

'National' Bulletin No. 20 of 32 pages is an index for National Bulletins No. 1 to 20. It is in considerable detail, the idea being to offer pipe information readily accessible to the editor, contractor, dealer, or consumer. The index is issued by the NATIONAL TUBE CO., Pittsburg.

An article entitled 'Dragline Cableway is an effective Tool for Sand and Gravel Plants,' by W. H. Wilms, reprinted from *Engineering Record*, June 5, 1915, has been sent us by SAUERMAN BROS., Chicago, who manufacture the Shearer & Mayer patented bucket used in the excavator described. The requirements of the buckets are severe.

In Bulletin Ka, the MESTA MACHINE CO., of Pittsburg, is a useful horsepower chart for transmission machinery including gears and pulleys. The chart appears as a cube with sides 3½ in. square. By writing to the company anybody interested can obtain a blue-print 16 times the size of this chart. Other machinery catalogues have been issued.

According to the NEW JERSEY METER CO., Plainfield, New Jersey, its air-meter is the only type of compressed air-meter which shows instantly, in cubic feet of free air per minute, the actual flow of air in a pipe or hose. It measures the consumption of any tool, machine, or apparatus driven by air; determines the net actual capacity of compressors and detects losses due to leaks, wear, and inefficient tools.

In its 48-page catalogue for 1915 the WEBER CHIMNEY CO., Chicago, states that over 1000 of its reinforced-concrete chimneys are in use in the United States and other countries. A long list is given. The largest is at the Colusa mine, Butte, Montana, and is 350 ft. high. Twenty-three pages illustrate construction methods and finished stacks. Some interesting discussion is given on the Weber 'coniform' chimney.

Centrifugal pumps, (double suction volute), turbine centrifugal pumps, centrifugal pumps, (single suction volute), and two-stage house pumps, are described in Bulletins 150, 151, 152, and 153 respectively of the A. S. CAMERON STEAM PUMP WORKS, 11 Broadway, New York. No. 104 covers the regular piston, boiler feed, long stroke piston, outside packed, sectionalized vertical plunger sinking, and other pumps made by the company.

The R. D. NUTTALL CO., Pittsburg, has issued two catalogues. No. 12 covers mine-haulage locomotive gears, pinions and trolleys, mining machine gearing, mine-haulage and general data for ordering industrial gears. No. 13 gives general data on Nuttall railway motor-gearing for Westinghouse and General Electric equipments, Nuttall trolleys, harps and wheels, flexible couplings of the spring and buffer type, and electric railway compressor-gears.

A 'Pneumercator' is a new accurate and practical apparatus for measuring and indicting the levels of liquids in stationary or marine tanks, such as water or fuel oil. It will also indicate the draft and displacement of ships. The instrument is simple in operation, air being forced through a pipe into the pneumercator by the liquid trying to enter a balance-chamber below the surface of the liquid. At the Exposition the PNEUMERCATOR CO., Monadnock Building, San Francisco, has this apparatus displayed.

EDITORIAL

T. A. RICKARD - - - - Editor THOMAS T. READ - Associate Editor

THE American Mining Congress meets here on September 20, 21, and 22, in the same week as the International Engineering Congress.

AMONG the freight going through the Panama Canal is 65% copper ore from the Kennecott mine, in Alaska, to the Perth Amboy smelter, New Jersey.

SILVER-LEAD ore from the Yukon is being shipped to San Francisco. One shipment of 600 tons, assaying 15 to 20% lead and 100 to 200 ounces silver per ton has just been received at the Selby smelter, and there is more of the same kind to follow. It comes from the McWhorter claims, near Minto Bridge, in the Klondike district.

CESSATION of fighting in South Africa, upon the conclusion of General Botha's successful campaign in German South-West Africa, should prove favorable to mining, by restoring many of the volunteer soldiers to their ordinary work and by preventing further interruption to peaceful industry.

IMMIGRATION for the fiscal year just ended was the smallest since 1899. It was about 460,000, as against 1,403,081 in the previous year. Moreover 362,642 aliens departed, so that the net gain was only 43,000, as against 769,276 the year before. Obviously these facts have a direct bearing on the supply of labor.

METALLURGICAL patents are interesting to our readers; so we have selected, for brief description and illustration on another page, the chief of those recently granted at Washington. This we shall continue to do at intervals. Patents have a large element of the unknown and unsuspected. Some of the apparently least important may prove epochal. Incidentally we note that these efforts to turn ideas into private property include much that seems trivial. The Patent Office Gazette chronicles the patenting of gloves, ties, drapery hooks, clothes-pressers, combination garments, bath-room fixtures, and the like. Attempts to make non-refillable bottles, resilient wheels, shock-absorbers, lock-nuts, and calculating machines are numerous as ever, but why a "device for attracting submarines"?

THE misfortunes of the Treadwell group of mines prove to have been exaggerated. In our last issue we gave the facts as they were transmitted to us. We are glad to state now that the accidents both at surface and underground are considered of minor consequence. The break to the shafting of the hoisting-engine at the Central shaft was repaired by obtaining a piece of shafting 13 feet long from Seattle, this piece being coupled onto a portion of the original. By reason of this quick repair, it was possible to resume hoisting at the end of last week. During the interval ore-crushers were placed at the No. 2 shaft, so as to supply the 300-stamp mill fully a week before the Central shaft became available. To obviate the possibility of any similar interruption to production it is intended to sink the No. 2 shaft to the same depth as the Central, and to keep a duplicate shafting in the engine-house. In regard to the caving of ground, we are informed officially that the loss of ore will not be serious and the workings are not endangered. We are also informed that Mr. Mackenzie's presence at Juneau was a mere coincidence, for he had gone thither in connection with the affairs of the Alaska Juneau mine.

INTERESTING, if true, is the comment to be made on many non-technical statements on technical subjects appearing in the daily press. A paragraph is going the rounds to the effect that the fume collected in the bag-house of the Mammoth smelter, at Kennett, has suddenly become marketable, by reason of its zinc content, for $8 per ton. This is wrong; the fume has been, and remains, unsaleable, because it is not amenable to profitable metallurgical treatment. The fact is that while the fume from the smelting of zinc-lead ores, as at the Selby or Midvale works, can be treated satisfactorily, at least for its lead content, the corresponding product of smoke condensation from complex copper-zinc ores cannot be beneficiated profitably by any method as yet discovered, although the Reed process gives promise of proving effective. As regards the lead-zinc fume, although the lead is recovered, the zinc passes into the slag, so that here also there is an opening for metallurgical inventiveness, such as is likely to be stimulated now, the price of spelter being equal to that of copper.

SOCIALISM is a word so loosely used that it has become discredited, for in the minds of not a few it is regarded as a cross between sentimentalism and anarchy. Socialism with an S may signify something like that; but socialism with an s merely asserts that cooperation is productive of better results, on the whole, than individual untrammeled activity. This latter kind of socialism lies at the foundation of this republic of ours. When the United States came into being the individual states agreed to forego the right to impose import and export duties at their borders, to meddle in interna-

tional affairs, or to advance their interests at the expense of their neighbors. In industry as well, socialism is yearly becoming more important. Much of our industrial progress may be traced directly to it. The activities of the United States Steel Corporation that were described in our issue of March 27 constitute socialism of the most practical kind. It is interesting to note that the opponents of Socialism are among the most ardent advocates of socialism. As an instance, we may quote from the testimony given by Mr. W. L. Saunders, chairman of the board of directors of the Ingersoll-Rand Company, before the Federal Trade Commission. He said: "The desirability of co-operation for foreign business is made acute by the importance and almost the necessity for having a varied line of products. A man who started in with a brake-shoe business, and who has reached out into foreign fields finds that he must also furnish axles, wheels, trucks, cars, and things of that kind to enable him to keep up a large selling organization, and a large volume of business, so as to keep his cost down in dull times. And if small concerns are able to combine and co-operate for foreign business, they would naturally bring into that combination a varied product." There can be no doubt that Mr. Saunders is exactly right in thus diagnosing the fundamental requirements of foreign trade development; we merely rise to remark that if this is not socialism, we do not know the meaning of the word.

WE publish an article on flotation in Australia. In our next issue we shall be able to give our readers the results of some good work with this process in Mexico. Meanwhile we note that in Australia just now it is easier to make a concentrate by frothing a mixture of water, oil, and ore than it is to sell the resultant product. At the annual meeting (in London) of the Zinc Corporation, the chairman, Mr. F. A. Govett, spoke plaintively regarding the inability of his company to sell zinc concentrate under contract with European buyers and the equal inability to cancel these contracts with a view to making new arrangements. To do the latter it was necessary to hale the alien enemy into court, a procedure blocked by sundry physical obstacles. Various schemes to build a zinc smelter in England had been discussed, and abandoned. The duration of the War was a factor so uncertain as to undermine the stability of such an enterprise, for any additional smelting capacity would probably be at a discount when peace was restored. This was the gist of Mr. Govett's remarks. In the absence of some measure of tariff protection or State assistance, it was inadvisable to incur a big expenditure for new plant. Moreover, as regards the erection of any new zinc smelter in Australia, it had to be remembered that the present production of concentrate is based mainly on old accumulations of mill-tailing that are fast nearing exhaustion. The current supply of tailing, or of ore, at Broken Hill will not justify an increase in smelter capacity in Australia, even if, as in England, the labor question did not loom in the background. Mr. Govett stated that 14,000 tons of zinc concentrate had been sold by his company on the American market, but the terms were by no means such as to warrant the expectation of persistent business. This aspect of the matter has been anticipated in our columns; in view of the extra freight and tariff, it is altogether unlikely that much Australian zinc concentrate will be sold in this country.

ON another page we review one of the four guide-books to be issued by the Geological Survey for the use of travelers on the transcontinental railroads. Anyone reading the preface by Mr. George Otis Smith, the Director of the Survey, will realize that this useful addition to the technical library is a minor result of the War, which, by placing an embargo on travel in Europe has diverted the intelligent curiosity of the American public to the less known regions of their own vast domain. In view of the stimulus to home journeys, it was decided "to entertain the traveler by making more interesting what he sees from the car-window." The entertainment is enhanced by making the interest more intelligent, and that in turn is effected by giving the traveler not only maps and photographs but geologic sections and industrial notes covering the physical and human history of the country traversed. These foot-notes are rich concentrates of information, summarizing researches scattered over the pages of many volumes. We congratulate the Survey on an achievement so manifestly useful. Knowledge, like charity, should begin at home. The globe-trotter who wanders across creation from China to Peru while remaining ignorant concerning his own country makes a great mistake, especially if his native land happens to be of such continental extent as to afford air, scenery, and industry of a variety not to be excelled by the rest of the world. He is only less mistaken than the man born in the New World who foregoes the chance to see the Old.

J. A. Holmes

With deep regret we record the passing of Joseph Austin Holmes, Director of the United States Bureau of Mines. This organization was created largely on his initiative and it was proper that he should have been its first administrative chief, having regard also to his fitness for its duties. He died at Denver on July 13 from a pulmonary illness that was known, among his friends, to set a definite limit to his life-work. Like Clarence King, under similar circumstances, he went first to Phoenix and then to Denver, without avail. Only 56 years of age, he had been Director of the Bureau of Mines for just five years, and a technologist on the Geological Survey for the six years preceding, during which period he had achieved honorable distinction as a clever, energetic, and persuasive official. Indeed, he combined tact with sincerity, technical ability with the humanities, energy with foresight, to such an exceptional degree as to render him peculiarly suited to direct the splendid work of the Bureau. He has set an example for those that follow. That is his legacy to his professional friends.

After the War

What most of us know about the course of the War is not nearly as interesting as what we don't know. In any attempts to forecast the result our wish is so much the father to our thought that unbiased judgment is out of the question. As to its duration, that also introduces factors of which we know accurately so little that prediction is futile. We may hazard the belief that the intensity of the conflict makes for brevity. We may assume that the forces acting for peace will gain momentum. In short, being optimistic, as any sane man must be in face of so much to make him pessimistic, we look forward to the end of the Great Horror. Whereupon the question arises: how will the restoration of peace affect the mining industry? It is apparent, in the first place, that the financial status of this country will have been enormously strengthened and aggrandized by the misfortunes of the European nations. A large accumulation of capital will be available for new enterprise. Next, the destruction of capital and of industry in Europe will cause a big demand to be made on the products of American manufacture. In the interval that must elapse before the commercial and industrial machinery of Europe is fully rehabilitated there will be abnormally large purchases of machinery and food supplies. For several years after the War the price of labor in Europe will be so high as to lessen the handicap under which the American manufacturer hitherto has had to compete. The heavy taxation and the increased cost of living will produce economic conditions highly unfavorable to European industry. We say these things in no feeling of exultation but merely in the effort to envisage the future. It is likely that immigration, which has almost stopped during the past twelve months, will be resumed in accumulated volume, for, once the warring populations are released from military service, there will be thousands anxious to leave scenes of horror and devastation in order to start a new life on this side of the Atlantic. Thus, if the United States is not dragged into the War, there should be an unprecedented opportunity for this country to be the manufactory of all that Europe will need for the great work of restoration and reconstruction. All of this will require the use of the metals; during the War for munitions; afterward for the resumption of peaceful industry. The amount of machinery that has been, and is yet to be, destroyed is enormous; the same is true of domestic utensils and appurtenances; moreover, the rebuilding of the world's mercantile marine, decimated by the torpedo and the shell, will call for big tonnages of copper, zinc, and tin. For steel there will be a demand such as the world has never seen. The amount of steel and cement required to repair the ravages of war, in railways, bridges, and buildings of every kind, is enough to stagger the imagination of any engineer. In short, civilization in its material aspect—unfortunately the one aspect emphasized by this scientifically organized calamity—can be restored only by a vast consumption of the metals. That means intensified mining. It means that during the next few years the miner will have to provide the materials required for re-building all that war has destroyed. On this continent the exploitation of mineral deposits is already feeling the stimulus of a great demand, but, unless we are greatly mistaken, it is only a beginning. We have seen some extraordinary rises in the price of metals; we shall see more, and some of them will not be transitory. During the next few years, possibly for a decade, the American mining industry will flourish as never before. The mineral resources of this continent, owing to its detachment from the War and the accumulated capital available in this country, will be exploited with a vigor and a profit beyond the expectation of the most sanguine.

State Mining Bureau

Time was, not many years ago, when the office of State Mineralogist suggested political corruption rather than the organized application of science to industry. California's political atmosphere even now has not the purity of the mountain tops, but it has been enormously clarified since the social upheaval that followed the days of the earthquake in 1906. Nowhere is the improvement more marked than in that part of the Ferry Building where the Mining Bureau is domiciled. Most of those engaged in mining in California have now a kindly feeling for this headquarters of useful information, and for the men at work there. The chief of the department, Mr. Fletcher McN. Hamilton, is a graduate from the State University and in his person represents the highest type of citizenship developed at that seat of learning. He succeeded Mr. W. H. Storms in January 1913; needless to say our good friend Mr. Storms was no relic of the corrupt past, but, let us say, the victim of the interregnum that divided it from the present dispensation. Since Mr. Hamilton took charge, the Bureau has done a great deal of hard work, despite a financial backing that is ill proportioned to the magnitude of California's mineral production. An excellent volume on the 'Minerals of California,' by Mr. Arthur S. Eakle has been published. Much useful labor has been directed to the oilfields, resulting in a report entitled 'The Petroleum Industry of California,' written by Mr. Roy P. McLaughlin, assisted by Mr. R. A. Waring. A complete geological map of the State is being prepared, besides mineral maps of the individual counties, indicating the distribution of the commercial minerals. The compilation of information on this subject has now been done for 35, out of the 58, counties. Naturally the finished work applies to the prineipal mining districts. Moreover, a large quantity of varied information is given, from day to day, in response to correspondence. This is not the least exacting function of the State Mineralogist's office, which thereby gives a helping hand to individuals desiring to exploit the mineral resources of the State. It is a pity, however, that a good deal of the statistical work done by the State Mineralogist should be duplicated by the local offices of

the U. S. Geological Survey and the Bureau of Mines, despite a friendly effort to avoid needless overlapping. It would be to the gain of the community if these various technical activities could be co-ordinated systematically. Meanwhile we can only congratulate the taxpayer that all of these agencies of exact knowledge are giving him a handsome return on his money. For the State Mining Bureau we have a particularly kindly feeling, for it is a home organization that has come through troublous years into a position of respect and appreciation. We recommend the mining population to make more use of it, to go to its library and museum, and give it the active support of a personal interest.

Diaz and Mexico

The passing of Porfirio Diaz may not be so significant as his resignation four years ago, but the event serves to punctuate the close of an era during which Mexico won a recognized position in the comity of nations. His life covered most of the history of the southern republic. He had served in the war that resulted in the transfer of California and the Southwest from Mexico to the United States. It is interesting to recall that the transfer was made under the form of a purchase for $15,000,000 only. He saw the Hapsburg attempt to found a throne in the land of the Aztec; he emerged successfully from the civil strife that followed, and finally with his strong arm fought his way to power as President. For 34 years he was the chief executive of Mexico. That was a long time for an unconstitutional ruler, since the successive elections were but a farce repeated. Yet he won respect and recognition, so that to this day there are many who think that his enforced exile was the worst thing that could have happened to Mexico. They forget that despotisms have one great defect: they do not perpetuate themselves. In the ordinary course of events a despotism ends as it begins, in a revolution. No constitutional successor is available; it is no case of "The King is dead! long live the King," nor is it the simpler way whereby the Vice-President of a representative government takes the chair as soon as the previous occupant has been summoned by a higher power. The downfall of Diaz gave Mexico a brief term under Madero and three years of misrule thereafter. That misrule should have had no suggestion of the unexpected. In the 55 years between the rejection of Spanish sovereignty and the day when Diaz took firm grasp of the reins of power, Mexico had 52 changes of government, all of them established by violence. That average of one per annum has been fully maintained since Diaz was driven into exile. To expect forthwith to establish representative government on the ruins of military despotism is to expect the impossible. Despotism thrives on serfdom. To substitute representative government requires that the foundation also shall undergo radical change. A stream cannot rise higher than its source. Constitutional government cannot stand on a basis of peonage.

That is the problem in Mexico. It cannot be solved by the wave of an enchanter's wand. A compromise is the only thing possible until such time as the native population is given education and freedom. That takes time. Meanwhile the co-operation of those responsible, inside and outside Mexico, may succeed at least in ending the anarchy that has prevailed for three years. Events appear to be marching to that desirable consummation. The man who killed Madero and insulted the American flag has had the impertinence to come to this country and to trespass upon its hospitality by plotting one more revolution. His arrest at El Paso, in company with Pascual Orozco, a bandit who formerly led a revolt against him, is a minor incident in the sordid melodrama. So is Orozco's escape while under bond. Meanwhile Pablo Gonzales has led Carranza's troops to the successful capture of the city of Mexico, defeating the Zapatistas in some minor engagement; but the capital has no military importance, and not much political prestige, now that the treasury has been emptied and the city looted in the course of repeated incursions by various factional commanders. Mexico City is most important as a terminus of the railway to Vera Cruz and a place where many foreigners still linger. Other reports of battles at Aguascalientes and Monclova have come to hand, but the results are stated in terms as conflicting as the official news from Berlin and Paris concerning the fighting in western Europe. As a matter of fact, the fighting in Mexico has been reduced to guerrilla warfare, injurious mainly to peaceful onlookers. In response to the pronouncement from Washington, Carranza remains truculent, while Villa says he is willing to further a compromise, and peace; so say Angeles, Zapata, and others. If Carranza succeeds in further lessening Villa's control in the North, it may prove advisable for Mr. Wilson to recognize him as provisional president of Mexico. That is now probable.

Meanwhile the policy of 'watchful waiting' has proved more pleasant to the spectator than to the victim. Gaunt famine now stalks the land and pestilence like a buzzard flaps his wings. The bodies of dead men hanging from telegraph poles give a picture of something that is not exactly war. From many centres of population comes the cry of starving women and children. The people are weary of misrule and brigandage. Non-combatants, and that means about 99½% of the population, are tired of pseudo-military domination and long for the peaceful revolution that is to end the sanguinary turmoil. The state of Oaxaca has declared its independence of all the revolutionary gangs and announces boldly that it will maintain its sovereignty until the rest of the republic has come to its senses. The merchants of Oaxaca are quoted as saying that they are tired of the exactions levied by the successive factions. Other states may be expected to follow the lead. A Federal government that does not govern is an unnecessary expense. Will the Mexicans accept the aid of their northern neighbor, who has now proved his entire good-will and his disinterested desire to aid in the restoration of order? We believe they are coming to that.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more vaulable than casual compliment.

Precipitating Action of Carbon in Cyanide Solutions

The Editor:

Sir—The recent article in your journal on the above subject by W. R. Feldtmann and one on much the same subject by Morris Green, both of which have appeared in the *Transactions* of the Institution of Mining and Metallurgy, have gone far toward clearing up the mystery that has surrounded the action of charcoal and related products on gold in cyanide solutions. It might be well, however, to call attention to the fact that the two papers mentioned together constitute a strong case for backing up the assertion that this phenomenon can now be explained in terms of known laws.

For many years the precipitation of gold on charcoal has not been understood, and we have been prone to accept the fact as due to some special peculiarity of amorphous carbon which it would be hard to classify with any other phenomenon known. However, since the property of adsorption of ions by colloids has been firmly established, there have been more or less serious attempts to find an explanation for the precipitating action of carbon in cyanide solution, but those doing the work have either been unsuccessful or forced to assume that the adsorption of gold-bearing ions in the pores of charcoal was of a slightly different kind than the absorption of ions by other colloids, or of other ions in charcoal itself. But the work described in the two papers, above mentioned, would seem now to offer an explanation of how gold is adsorbed into charcoal and why it does not behave like ordinary adsorptions.

In the development of colloid chemistry it has been found that there is a class of 'amorphous' substances, such as charcoal, meerschaum, colloidal gels, starch, cotton, wool, glass, coal, etc., which have the property of absorbing great amounts of gases, vapors, liquids, and even ions from solutions on their surfaces. Why crystalline substances do not exhibit the same phenomenon, at least in a measurable degree, is hard to explain, but crystal faces, and molecular orientation, with consequent close packing of the molecules, seem to prevent adsorption.

It has been known since 1777 that charcoal would adsorb gases, but the only work that has thrown any light on the real nature of the process has been done in recent years. Mr. Green has clearly shown that charcoal containing adsorbed carbon monoxide is capable of precipitating gold; that charcoal which has been exhausted in a high vacuum at elevated temperatures shows a very low precipitation value, but that its precipitating value is restored by allowing the CO to be re-adsorbed, or by heating the charcoal in air. Such being the case, it may be well in this connection to call attention to the recent work of Rhead and Wheeler on the mode of combustion of carbon (*Journal* of the Chemical Society, Vol. 113, pp. 461 and 1210, 1913). They found that the charcoal examined would adsorb oxygen, which later combined directly with the carbon of the charcoal, forming a "loose physico-chemical" complex that later broke up into carbon monoxide and carbon dioxide, depending on the amount of carbon monoxide left adsorbed on the surface of the charcoal. This fact explains the sudden evolution of a great volume of oxides of carbon when Mr. Green heated his charcoal *in vacuo* to 500°C. Based on Mr. Feldtmann's inference that a carbonyl aurocyanide is formed by the inter-action of the adsorbed gold-bearing ions and the adsorbed carbon monoxide, we have an explanation of the phenomenon in terms of colloid chemistry. The aurocyanide ions, are doubtless adsorbed in the charcoal in the same way that permanganate ions are, and could be washed out again with an excess of cyanide solution if it were not for the fact that these ions react with the carbon monoxide held adsorbed in the charcoal, forming an insoluble compound, which can doubtless break up still further to form the metallic gold that Mr. Green reports that he saw. When a solution capable of dissolving the compound of gold is used, the charcoal will give up its load in the same way as it gave back the unaltered aurocyanide ions, as shown in the column of figures headed "adsorbed gold" in one of the tables prepared by Mr. Feldtmann. However, even with all of the gold merely adsorbed, there will always be a loss of some gold held adsorbed on account of the fact that there is a definite equilibrium reached between the solution and the adsorbed ions and that the latter can only be completely removed by an infinite number of washes. These conclusions are based on colloid-chemical principles. I am of the opinion that it would be well to take these facts into consideration in connection with Mr. Feldtmann's work, even to a greater extent than was done by him. For example, he was able to re-dissolve all of the gold in alkaline sulphide solutions, but it would have been a most interesting experiment if he had applied another cyanide wash after all of the insoluble carbonyl aurocyanide had been removed from a sample of charcoal saturated with gold. This might have shown whether there was any free gold formed in the pores of the charcoal that had been protected from solution in cyanide by the insoluble carbonyl aurocyanide.

It is easy to see, in the light of Rhead and Wheeler's work, why charcoal is re-vivified for the precipitation of gold by simply heating in air, as more carbon monoxide is generated in the pores of the charcoal. It is also easy to see why freshly-heated charcoal has a higher precipitation power than charcoal that has stood some time, as the freshly-ignited charcoal is doubtless saturated with carbon monoxide, while in the older samples, part of the carbon monoxide had diffused away faster than the carbon-oxygen complex could break up at ordinary atmospheric temperatures. Moreover, the fact shown in Mr. Feldtmann's tables of figures that the charcoal never becomes quite saturated, but continues to precipitate gold slowly, is to be coupled with the slow breaking-up of the "physico-chemical" complex into carbon monoxide and carbon dioxide, due to the removal of CO by combination with the aurocyanide ions. Mr. Feldtmann ascribed this latter effect to some other chemical reaction that might be set up, but the figures upon which he bases this surmise show only one figure that could uphold his assumption. This table is quoted below, together with an additional column of figures, showing the velocity of precipitation of gold during each successive interval observed by Mr. Feldtmann:

Contact, hours.	Gold precipitated, mg.	Mg. gold per hour.*
3	14.0	4.67
6	16.2	0.73
9	18.0	0.60
12	19.6	0.53
18	20.6	0.17
24	20.8	0.03
36	22.0	0.10
48	24.2	0.18

*This column I have added.

If the figure for the 24-hour period were discarded, it would be hard to draw the same inference as Mr. Feldtmann. Not knowing the care exercised in these experiments and how much reliance Mr. Feldtmann is ready to put on one figure, I am not prepared to criticize the observation further than to call attention to the fact that a continued precipitation of gold could easily be explained on the ground of facts already known about charcoal, and which do not call for the assumption made by Mr. Feldtmann.

Mr. Green was not able to make carbon monoxide react with a cyanide solution of gold by simply bubbling the gas through it, but felt that the high state of pressure of the adsorbed gas in the pores of the charcoal might easily account for the reaction taking place. In this, I fully concur. The work of Dewar indicates that the density of several adsorbed gases is greater than, or nearly equal to, the densities of these same gases when liquified. Thus CO_2 when liquified at a temperature of 15° C. has a density of about 0.8, while the density of the CO_2 adsorbed in charcoal is at least 0.7. These measurements made by Dewar more or less justify Mr. Green's inference, and only illustrate the magnitude of the forces at work, be they those of adhesion or what not, that cause the concentration of films of gas or of liquid on the surfaces of this kind of amorphous substance. In the case of water adsorbed on starch grains it has been estimated that the force acting is 2073 kilo. per sq. cm. (Rodewald and Kattein, in *Zeit. Physik. Chem.*, Vol. 33, pp. 540-544 and 593-604, 1900). For this reason it is not at all surprising that Mr. Green was able to make small amounts of gold precipitate on charcoal that had been heated in a high vacuum to 500° C., as a perusal of Rhead and Wheeler's work will show that they went to much higher temperatures without being able to remove all of the adsorbed gases from the charcoal. Furthermore, it is a matter of common knowledge that there is a film of adsorbed air, moisture, etc., on the surfaces of glass vessels, that cannot be completely driven off, even *in vacuo*, at temperatures as high as the softening point of glass. This fact has been observed repeatedly in the incandescent lamp industry.

All of the amorphous substances mentioned, such as charcoal, meerschaum, etc., when immersed in solutions, likewise tend to adsorb some of the ions from the solutions, and in amounts varying with the substances in question. The laws of adsorption have been set forth in text-books on colloid chemistry, and have been referred to for some time as a possible explanation of the precipitation of gold on charcoal, but it was not until Green had proved that it was connected with the adsorbed carbon monoxide and the formation of an insoluble compound that we really gained an idea as to the true situation. He tried some of the other amorphous substances mentioned and got no precipitation. Supposedly there was no adsorbed carbon monoxide to cause reaction in these other substances. I am not greatly surprised that Mr. Green did not get appreciable precipitation on anthracite coal, as it is too highly compressed a product to have much pore-space, though some action on coke might be expected, but not having descriptions of the history of the coke samples used, it is hard to judge. My own experience with the lower-grade coals, however, is that they act much like charcoal, are capable of adsorbing permanganate ions, and that they adsorb oxygen, with which they combine later (at ordinary temperatures) liberating carbon monoxide, carbon dioxide, and water (see Technical Paper No. 65 of U. S. Bureau of Mines).

Mr. Feldtmann's observation that the use of oxidizing agents such as bromo-cyanogen in the cyanide solution hastened the precipitation rather than assisted in resolution of the precipitated gold, accords with another known property of the charcoal, that property of yielding a mixture of CO and CO_2 when treated with solutions of oxidizing agents. See Hofman, Schumpelt, and Ritter in '*Berichte des Deutschen Chemischen Gesselschaft*,' 1913, 46:2854.) Therefore I feel justified in adding to Mr. Feldtmann's conclusions the statement that facts already known about charcoal, taken in conjunction with well-known colloid-chemical principles, further support the work of himself, as likewise that of Mr. Green, in an explanation of the phenomenon of the precipitation of gold on charcoal.

O. C. Ralston.

Salt Lake City, June 5.

Relative Error in Alluvial Sampling

The Editor:

Sir—Probably no two alluvial engineers are agreed as to the most effective method of sampling gravel. The different types of drills, both hand and power, have their own adherents; and in the same way, different systems of shaft-sampling find varying favor. The tendency of every individual is to favor the methods which have brought the best results in his own particular experience.

Everyone realizes that the personal equation of the examining engineer is the determining factor in the sampling of any property, no matter what the method used. For this cause, the accuracy of any method of sampling may often be brought into disrepute, when the machinery of the sampling itself may not have been entirely at fault. There are, however, certain factors of unreliability which may generally be conceded to be present in all methods of sampling; and it is of a few of these that I wish to treat.

The best known forms of hand-drill are exemplified by the Empire, or Banka, type; and the best known form of power-drill is, of course, to alluvial men, the Keystone. It will suffice for my present purpose to show the chances for error that commonly attend each one of these methods of sampling, in the case of drill-holes.

Again, in shaft sampling, there are two distinct methods commonly used, each of which has its failings. One is the washing of the entire material taken from the shaft through a sluice; the other the sampling of the sides of the shaft by open-cut after it has been sunk.

To begin with the methods of drill-sampling, let us take the case of the Keystone. The commonest form of this drill used in placer prospecting is the No. 3 traction. The weight of stem and bit is about 800 pounds, and the inside diameter of the casing is 6 inches. The diameter of the bottom, or flare, of the shoe, is 7½ in.; hence in order to be assured of the proper core within the casing after a drive of one foot, approximately 18 in. of material should be within the casing. It may be possible to maintain this ratio. Personally, I have never been able to do it, except within wide limits. Where the driving is being done in pay-gravel, the whole question of allowance to be made is simply up to the judgment of the engineer. No established rule will fit the varying conditions of the gravel. Then, having drilled your hole, the best method of saving your entire core is, of course, to pump directly after driving, without using the drill, wherever it is possible to do so. It is possible only in the case of fine gravel. In most cases, the driving-blocks have to be taken off, and the heavy drill lowered into the hole, there to punch out part of the core from the casing. How much? This can only be judged by measuring each pumping—for every drive, that is—and applying a factor of expansion, as well as making allowance for the run-off in slime. This method is absolutely incompatible with making any speed, and the usual practice is to measure up only when the sluice-box begins to get full, or nearly so.

So, you probably do not have the core that you should have for your drive, and you don't know how much of the core you have saved. The sum total of measured volume may, if your luck is good, come somewhere near the estimated theoretical volume of the core. When you come to estimate the yardage-value for the hole, you commonly use a cross-section that lies between the area of the flared shoe and the area of the inside of the casing. The experience of many engineers has shown that Radford's factor, of 0.27 ft., comes somewhere near giving satisfactory results in the majority of cases. In other words, in summing up results, we assume that all other assumptions with regard to the volume of core from which the gold obtained was secured, and of which it is supposed to represent the average content, have been covered by the use of Radford's factor.

Consider next the error that enters into hand-drill sampling. As the usual Empire casing generally used is 4-inch, and the weight of the tools is much less than in the Keystone, the chances are that the errors above mentioned do not enter nearly so far into calculations. There is less material to handle, the rotated pipe undoubtedly does help in securing the proper amount of core, and the total core for the drive may readily be measured up and checked with the theoretical core without cutting down the speed of drilling. In this case, a flexible system of keeping the log is applicable such as is impossible in the case of the Keystone.

On the other hand, the Empire has faults peculiarly its own. The ball-valve pumps certainly drive a portion of the core out when they encounter a pebble too large to go into the opening. A new tool has recently been supplied by the Empire people, called the Knox tool, which is supposed to overcome this difficulty by enabling the removal of large pebbles before pumping. How effectual it is, I am unable to say, not having used it as yet.

Also, in encountering larger than 4-in. boulders with the Empire, a certain amount of error is caused by the pushing aside of material. As there is no flare to the Empire shoe, the factor for one foot is taken as 0.1134. This should be subject to a discount—or rather an increase that will act as a discount factor—just as much as in the case of the Keystone. An arbitrary cutting down of yardage-values by 15% will accomplish the same result, however. This discounting is, of course, a confession of weakness and evidence of a desire to remain on the safe side.

Consider next shaft-sinking. I have contended elsewhere, and still contend here, that no ground is properly prospected without the information derivable from a number of shafts. However, unless the cost of examination is to become prohibitive, no ground can be thoroughly prospected by means of shafts, for obvious reasons. Here again comes the question of the judgment of the examining engineer. How many shafts need to be put down before the drill-sampling may be considered properly checked, and how shall they be placed so as to give the maximum of information for the minimum of expense? The answer to this problem will depend en-

tirely upon sets of conditions, which are never the same for any two properties.

When all of the material is taken from a wet shaft and put through a sluice-box, and the content of the ground calculated from the recovery and the amount of material taken from the shaft, error is certain. Where pumping is necessary, the suction of the water is liable to draw in gold from all around the shaft. I had occasion to check some shaft-work of this type in Oregon recently. The gold was rather light and flaky, and it was evident that the shafts had been unintentionally 'salted' in the above manner to a high degree. In this case, the drill proved to check much closer with the real value of the ground than the shafts. On the other hand, I recall a case of shaft-work done in northern California in exactly the same manner. In this case, however, the holes were absolutely dry. When I came to hydraulic the property afterward, the clean-up results checked startlingly well with the shafts. Had the ground not been pretty even in its gold content, this would never have been the case, of course.

My personal preference of all sampling is to take a measured open-cut down through the bank, and weigh all the gold in it. For this reason, I am an advocate of the second method of shaft-prospecting, namely, that of sampling one or more sides of the shaft after it has been sunk. In the case of wet ground, this method affords some little difficulty, and must be done with extreme care; and in the case of running or loose gravel it becomes almost impossible of accomplishment. Wherever open faces are available, as in old hydraulic workings, this method is applicable, and in Peru I have sampled tailing by dropping shallow shafts and open-cutting the sides. In firm ground, without too much water, this method is, to my mind, the most accurate of all. It may be necessary sometimes to drain the shaft from a sump in the bedrock for a day or two before the ground becomes sufficiently firm to sample in this manner.

However much opinions may vary as to methods, I think it will be generally agreed that the whole thing depends upon the judgment and experience of the man who is doing the work. We naturally expect our drill-manufacturers to be enthusiastic regarding the simplicity and ease of operation of their respective machines; they would be poor optimists did they not—and also poor salesmen. However, most firms prefer to furnish with the drill a man who knows how to operate it, from a mechanical standpoint, but the furnishing of an engineer to direct the examination is naturally somewhat beyond their scope.

We hear a great deal about the accuracy of estimation that is possible through improved methods of drilling, but very little about the possibility of error in the various types of prospecting machines, and the necessity of the use of judgment in eliminating and discounting this error. To me, this is a factor that cannot be emphasized too strongly, even at the risk of being misunderstood.

CHARLES S. HALEY.

San Francisco, July 12.

Conditions in Sonora

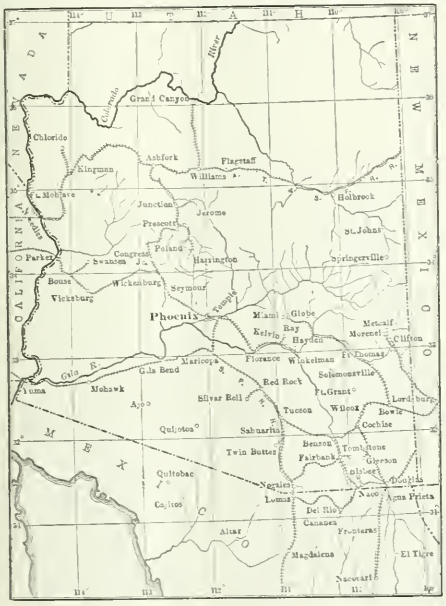
By AN OCCASIONAL CORRESPONDENT

My own experience is largely confined to the northwestern part of Mexico, particularly the state of Sonora. The present confused conditions are due largely to an agreement made with General Scott, of the United States army, whereby the Villistas, or followers of Francisco Villa, were diverted to Nogales while the Carranzistas, or followers of Venustiano Carranza, were centred at Agua Prieta. The intention of this friendly American interference was to prevent promiscuous shooting across the boundary, but in Mexico the agreement produced a condition approaching chaos. The Villistas were ordered by the U. S. authorities not to attack Agua Prieta, but the Carranzistas in Agua Prieta were allowed to raid the Villista country south and west; thus an absolutely impossible condition was created. The railroads running from Nogales to Cananea were destroyed by the Carranzistas, while the railroads running from Agua Prieta to Nacozari and El Tigre were destroyed by the Villistas. Strenuous efforts were made by the mining companies to adjust matters to such an extent as to enable them to continue or start operations, for Cananea was shut-down for several months. These were aided somewhat by the State Department, after Mr. Bryan's withdrawal. Thus eventually permission was accorded by both parties to operate the mines, and to repair the railroads, each side retaining 100% of the war taxes now imposed, these taxes being two or three times greater than those levied before the revolution commenced.

In consequence of the depreciation of Mexican currency and the absolute shortage of provisions throughout northern Sonora, the mining companies and the surrounding population have resorted to what is practically barter. The farmers, when bringing supplies to the mines, will often refuse money, preferring to be paid in coffee, sugar, or clothes. The miners themselves will work for three or four days only, and draw food and supplies from the store, but immediately the mining company refuses to give out any of its limited stock and proceed to pay wages in paper, they cease work. The miners will no longer do a day's work for paper money. In order to offset this, the Cananea mining company, whose mines have been closed for several months at a cost of considerably over half a million dollars, and are now resuming operations, paid their men last week in Mexican silver dollars, which were purchased and shipped from China, to the amount of about $400,000 American currency. This action on the part of the Cananea management has resulted in a strong migration, not only from the mining camps of Nacozari and El Tigre to Cananea, but from the rival contending armies.

The struggles of the Villistas and Carranzistas in Sonora can have no effect whatever on the final pacification of Mexico; their performances partake of the character of *opera bouffe*, were it not for the enormous cost to the American industries operating in that state. These are the chief sufferers. It will be understood that

no white labor is now employed in northern Sonora, except for supervision and technical work. On account of the damaged condition of the railroad south of Agua Prieta enormous quantities of copper concentrate have accumulated at Nacozari and it is reported that the El Tigre mining company has as much as $300,000 worth of bullion and concentrate on hand. Of course, accumulations of this kind serve to invite the disorganized elements of the country to attack and raid the mining settlements, as they did some two years ago when 'General' Inez Salazar raided the Tigre 'camp' and stole some three tons of bullion. When his band of 375 men left



MAP SHOWING THE ARIZONA-SONORA BORDER.

they were loaded with provisions and supplies as heavily as possible. The company at that time was fortunate in that Federal troops were already on the way from the north, and Salazar's band was quickly stampeded, leaving the silver and other loot tied to burros that wandered over the mountains. The bars of silver, each weighing about 200 pounds, were so heavy that when the burros lay down, they were unable to get up again, so that, having been abandoned, they died. The Tigre miners, who were searching the hills for the lost bullion, were able to locate it by means of the buzzards circling overhead. As a matter of fact, every bar was recovered and Salazar was thoroughly defeated by General Obregon, now the right-hand man of General Carranza, in his first battle of any importance.

Power is supplied to the Tigre mine by meaus of a power-line 65 miles long transmitting 1000 horse-power through a current of 40,000 volts. This line has been repeatedly cut by the contending factions, but it is probable that if it were not in existence, the mine would have ceased operations many months ago, as, on several occasions, all the horses and mules belonging to the freighters working for the company have been stolen. So far it has been possible to repair the line as soon as it has been cut.

There has been very little actual fighting in Sonora. There have been no pitched battles, the fighting being of a desultory character. It would almost appear as if the object of both factions was to get into such a position that they could tax the mining companies. The large land-owners have escaped into the United States; the crops planted this year are of small extent, and, while there does not appear to be any case of actual starvation in northern Sonora, conditions could hardly be any worse than they are, the only redeeming feature being the fact that the three large mining companies continue operating to the best of their ability. While unhappily they furnish funds to the contending factions, they also supply a livelihood to the surrounding population.

Nacozari and Tigre will both, no doubt, be compelled to adopt the Cananea plan of paying in Mexican silver, although the Villista faction now in control in Sonora (with the exception of Agua Prieta) is already objecting to the abandonment of the use of the paper currency printed by them. There is no doubt that the payment of silver itself to the miners will tend to expand the barter now in vogue, as all the various paper issues, which now amount to many millions of dollars, are legal tender, and are refused by everybody who can. Speaking generally, the outlook is that unless some one of the contending factions is speedily recognized by the American government and permitted to strengthen itself by means of foreign loans, the United States will be compelled to intervene, willingly or unwillingly. If the United States fails to recognize any government in Mexico, the present conditions can only grow steadily worse, as none of the parties can receive enough support to establish permanent pacification throughout the entire country. The working population shows in many ways that it is absolutely tired of the never-ending strife, but the absence of public spirit and the inability to express public opinion make its desires of little importance to the revolutionary leaders.

As between the various leaders, Villa is a good soldier, and, with a small army under his personal direction, has been generally successful. As soon as he endeavors to undertake administrative work, or military work on a larger scale, his efforts are no longer successful. Carranza, on the other hand, is not a soldier, and while it has not been possible for the State Department in Washington to handle him as satisfactorily as it has Villa, he evidently is a better representative of the Mexican constitutionalist movement. Zapata is of an inferior type to both of the other leaders; he is merely a glorified guerrilla leader without real political purpose.

PANAMA CANAL is making an operating profit. In April, tolls amounted to $442,416. The profit after paying for operation and maintenance was $84,108. From June 30, 1914, to May 1, 1915 the revenue was $3,337,716, and expenditure, $3,377,196.

Accident Prevention by the Steel Corporation

By A. A. WILLOUGHBY

In the article on the Safety, Sanitation, and Welfare Bureau of the United States Steel Corporation which appeared in the Mining and Scientific Press of March 27, 1915, mention was made that the 1914 figures would shortly be available. It is now possible to give these in completed form as a sequel to the article, which was the first to appear in a technical magazine describing the activities and giving the various expenditures of the Bureau.

During the period from January 1, 1911, to January 1, 1915, $24,874,892 was expended by the Bureau under the direction of C. L. Close, its manager. The following table shows by years the various expenditures and the apportionment to the different funds.

	1911.	1912.	1913.	1914.
Relief for men injured and families of men killed	$1,637,000	$2,587,516	$3,013,638	$2,253,901
Accident prevention.	750,000	595,649	660,593	565,334
Sanitation and welfare	1,250,000	1,068,253	1,600,242	615,966
Pension Fund—				535,056
Pension payments	200,000	358,780	422,815	511,967
Additional benefit payments	.....	56,175	43,379	35,621
To permanent fund.	500,000	500,000	500,000	500,000
Allowances to employees under stock subscription plan.	750,000	1,000,000	1,000,000	1,000,000
Totals	$5,287,000	$6,166,373	$7,240,667	$6,017,845

Grand total of $24,711,885.

The percentage of hand-labor accidents to all other accidents by months from April 1913 to March 1915, is of interest: 1913—April, 47.96; May, 46.77; June, 43.93; July, 44.58; August, 47.51; September, 43.83; October, 46.11; November, 45.25; December, 44.54. 1914—January, 42.40; February, 42.69; March, 46.33; April, 44.33; May, 47.34; June, 45.25; July, 45.44; August, 44.65; September, 46.69; October, 46.93; November, 45.12; December, 41.81. 1915—January, 46.21; February, 48.07; March, 48.12%.

Of most interest are the figures showing the percentage of decrease in the accident rate since 1906 per 1000 thousand employees:

	Number saved from serious injury.	Per cent decrease.
1907	532	10.40
1908	783	18.21
1909	1,236	25.28
1910	2,215	43.49
1911	2,012	41.26
1912	2,023	36.06
1913	2,273	38.29
1914	1,748	40.52

Owing to a change made in the reporting of accidents since January 1911, more accidents are classed as serious than formerly, but the decrease is steady; a most favorable showing for the efficiency of the Bureau.

In recapitulation and for purposes of comparison, the classification of causes of accidents in the various lines of industry represented in the Corporation's activities for 1913 and 1914 are herewith given:

	1913, %	1914, %
Hand-labor	43.88	45.04
Railroads	4.22	4.02
Mines	15.10	13.76
Machinery	5.20	4.73
Burns	6.94	6.44
Falls	7.73	8.79
Eyes	...	5.11
All other causes	16.93	12.11

In studying the above it is to be seen that there is little fluctuation from year to year. A perceptible decrease was made in the mine group. The percentage ascribed to mines includes the following:

	1913. %	1914. %
Haulage or skip track	35.23	36.71
Slate, rock, ore, or coal falls—		
From roof	26.62	15.66
From side	16.76	27.14
From face	0.93	1.75
Slides or cave-ins	6.95	5.67
Steam-shovel in open pit	4.11	2.20
Live stock	2.25	3.12
Chutes and raises	0.99	2.20
Gas and smoke explosions	0.73	1.25
Cage accidents	0.53	0.74
Shaft accidents	1.06	1.22
Premature explosions	0.47	0.42
Delayed blasts	0.26	0.06
Blasting operations	3.11	2.46

In this connection it is interesting to note in the classification of causes that accidents due to delayed blasts have been reduced to a negligible quantity. The three leading causes, haulage and skip-track, and falls from roof and from side still holds a large percentage, although the falls from roof showed a healthy decrease during the past year.

Metal output of the Eastern or Appalachian states in 1914 was as follows: mines, 45 gold placer, 36 deep gold, 7 zinc, and 7 copper; gold output, 8397 oz., increase of 380 oz.; silver, 100,727 oz., a decrease of 10,487; copper, 19,555,362 lb., (mainly from Tennessee), an increase of 409,367 lb., lead. 254,000 lb., a large decrease; and spelter, 169,716,954 lb., (mainly from New Jersey and Tennessee) an increase of 8,749,994 pounds.

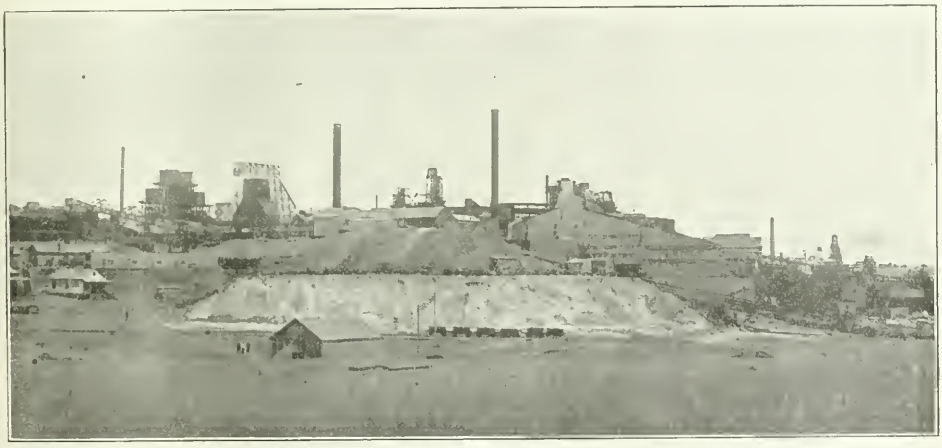
Electric power generated by the plant at Gatun, Canal Zone, in May totaled 2,367,000-kw. hours.

Flotation in Australia

By CHARLES S. GALBRAITH

My first contact with 'oil-flotation' was the reading of an article on Elmore's first patented process in 1899. I was then metallurgist to the Lake George Mines, in New South Wales, endeavoring to make sufficient funds by cyaniding the limonite gossan ore in the upper levels of the Lake George lode in order to extend development into the immense bodies of complex sulphides below the water-level. The intermediate zone—between gossan and dense sulphides—had been successfully smelted in blast-furnaces, but this amenable ore had 'cut out' and the smelter plant was idle. After thorough experiment with the gossan, the fact was established that a small profit could be made, but the quantity of ore available was insufficient to justify the erection of further plant or supply funds for deep development. So a 'close down' was ordered. The sulphide orebody is of a very dense nature with extremely finely divided mineral particles, the gangue being silicious. Blende (representing 14% Zn), galena (representing 5% Pb), and pyrite (representing 1% Cu) were the principal minerals, but gold (2 dwt. per ton) and silver (3 oz. per ton) were the fascinating additions, which, together with the size of the lode, led to so much hard work and money being expended on a solution of the problem. Wet concentration was out of the question owing to the fineness of the mineral grains. The mine went into the hands of a firm of second-hand machinery merchants, and when last I heard of them they were making quite an income from continuing the operations of pumping and precipitating the copper contained in the mine-water with scrap iron, which, alas, abounded on the premises. That this particular ore is amenable to modern flotation treatment seems certain, but in 1900 a sample parcel sent to the Elmore people in England was reported unprofitable, owing to the cost for oil. It will be remembered that Elmore's first process was that of suspension of minerals *in* oil—which has long since been abandoned for the 'greasing' of the mineral particles *with* oil. Lake George ore is one of the many problems of the kind that will be profitably solved—the huge bodies of the Mount Reid and Roseberry districts in Tasmania are others—when the money and the man are available.

Broken Hill is far famed, and the history of the metallurgy of that district is of particular interest. The



THE BROKEN HILL PROPRIETARY MINE AND MILL.

Broken Hill Proprietary mine was discovered about the year 1882 and the original syndicate shares issued at five shillings ($1.20) rose to £420 ($2016) each. In those days, native silver was dug out in tons, and chlorides were easily reduced to the metal. Next came the carbonates (still obtained in some of the leases, notably Block 14 and British) and although this zone was not such a 'gift' as that above, the metallurgical problem was still a 'cinch.' Fortunately for the lucky shareholders the carbonates (rich in lead and silver) lasted for a decade. The third period was marked by the sulphide problem, which will last indefinitely. The upper regions of the unoxidized lode-matter were rich in galena with only a trace of blende, consequently wet concentration was straight-forward; although it must be remembered that modern concentrators did not then exist, and jigs were followed by canvas belts and Frue vanners, etc., later. Today the deeper levels of the mines are rich in blende, while the galena is gradually disappearing. The Proprietary mine and Block 10 are the deepest on the field,

and both are now zinc propositions; in these mining has been for the present practically confined to prospecting work. The presence of rhodonite in the gangue makes both mining and concentration of the comparatively low-grade deep-level ore very difficult and expensive. Rhodonite, a manganese silicate with specific gravity 3.5 and hardness about 7, is exceptionally tough and difficult to crush. It constitutes undoubtedly the worst bugbear to the Broken Hill mill-man. Steel in the stopes refuses to cut it, and crushing machinery 'on top' shirks its work, sliming the mineral particles while it leaves the rhodonite in large grains. Wet concentration consequently is not ideal. Therefore Charles Hylton, formerly mill-superintendent at the Proprietary, was well content to send 54% lead concentrate to his company's smelters at Port Pirie. The 'free milling' ores of the North and South mines—where zinc is low and rhodonite rare—give a better recovery and a higher grade (up to 72% Pb) of concentrate, but these mines are fortunate and are not so deep as the Proprietary.

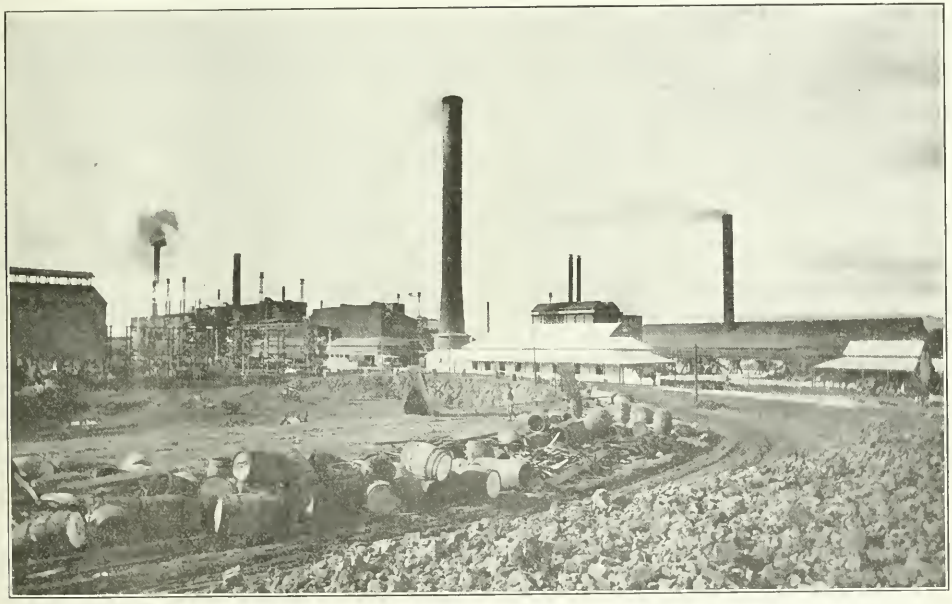
During the lead period, with no means of separating the zinc sulphide, and no market for it, the concentrates consisted wholly of 'lead' (galena averaging about 6% Pb) and the zinc tailings were stacked, pending solution of the 'zinc problem.' There were *some* dumps at Broken Hill. About 1905, experiments having been continuously carried out by various chemists and metallurgists, notably Potter, Delprat, and the Minerals Separation Co., on Broken Hill ores, there was a sudden rush to buy the zinc tailing. Syndicates were formed hurriedly; all available tailing-dumps or 'heaps' and most of the mill-outputs were secured. The zinc era had commenced. Though not the first in the rush, the Zinc Corporation was by far the largest buyer, obtaining both the South mine dumps, and those of Blocks 10 and 14. The North mine dumps and output were secured by the de Bavay Treatment Co., now the Amalgamated Zinc, Ltd., which by arrangement, has also undertaken the treatment of output from both the South and Block 10 mills. The Proprietary has, of course, held on to its own, and was the first to succeed with a practical flotation process, the Delprat. The Central mine, controlled by the Sulphide Corporation, also treats its own tailing and output, by the Minerals Separation process. At the Proprietary mine, the Delprat process was evolved by the company's staff, headed by the general manager, G. D. Delprat, and has been most successful. The Proprietary company, unlike any of the others except the Sulphide Corporation, which smelts its lead concentrate only, ships bullion. It has both lead and zinc smelters of its own, and is indeed so enterprising that it has now erected and is operating the only steel works in Australia, utilizing its Iron Nob ore, in South Australia, which is high in iron and was developed for flux at the lead smelters years ago, so that it can well afford to produce a concentrate of lower grade than these other companies, which, prior to the War, shipped their product to Germany. The penalties imposed by these German smelting works on concentrates of comparatively low zinc-content were so severe that an increase of 1% zinc meant a corresponding increase of about thirty shillings ($7.20) per ton of concentrate. Shipments assaying 47% zinc and over were well sold; those under 45% zinc were a poor product. A sliding scale was recognized by the German buyers, and as no credit was allowed for lead content, the aim of the seller of concentrate was to keep the zinc high, while a domestic smelting company, such as the Proprietary, could be satisfied with a product containing only 40% zinc or under. To see the Delprat units at work even in 1907 was an eye-opener to observers, who, by the way, were numerous and freely invited whereas the equivalent of "fix bayonet, guards" had to be passed before entrance could be obtained to the opposition mills, and in some instances would not be allowed at all. A Delprat unit consisted of a large spitz-box, fed continuously by an automatic 'push eccentric' feeder, the falling (dry) pulp meeting an upward stream of hot salt-cake solution (acid), the mineral was 'elevated' (while the gangue 'dropped'), and floated with the overflow into the collecting launder. The tailing was released from the bottom of the 'spitz' intermittently (as it accumulated, and so as to save loss of solution) upon a 12-in. belt-conveyor, and thence carried to a 'pass' for mine-filling. The concentrate-launders discharged into bins, with drainage-bottoms and the liquor was pumped back, to be made up to the required strength by the addition of salt-cake. Each unit or 'spitz' has a capacity of 20 tons ('long') per hour. 'Output,' 'economy,' and 'profit earning' were all so obvious that the freely confessed low concentrate did not worry the thoughtful onlooker or diminish his admiration.

While the 'Delprat' was operating successfully in 1906-1907, other processes at Broken Hill were under experiment, to be scorned and ridiculed in turn, particularly the plant to which I had just been appointed manager, the Amalgamated Zinc. The Zinc Corporation was in 'some state,' and varied both process and management about once per month. Spelter was high, $105 per ton—as was lead also. A boom was on. Shareholders argued that if the 'Delprat' was a success, and the 'Minerals Separation,' also why then couldn't the de Bavay, Zinc Corporation, and other companies get on the dividend list and obtain the advantage of the boom prices? Hysteria reigned, and it was not until that was cured, probably in the case of the Zinc Corporation by H. C. Hoover and W. J. Loring, that a solution was found. It must have taken excellent and influential finance to save the Zinc Corporation from entire collapse, and, although the cost was tremendous "more power to those responsible for the present happy result." In a smaller degree the Amalgamated Zinc Co. (de Bavay's) had its hysterical period, but strong financiers held the controlling interest in this case, and the small holders were kept quiet. M. de Bavay, a Frenchman who has occupied the position of chemist to the Foster Brewing Co., Melbourne, for many years, and who is also a *vigneron* in Victoria, entered the lists of flotation patentees in a peculiar way. When the Potter *v.* Delprat litigation commenced—Potter being another brewer—they called in de Bavay as an expert chemical witness. Potter's argument was that the acidulated solutions, when

in contact with the pulp, generated H_2S and H by partial decomposition of the mineral grains. Delprat, on the other hand, insisted that the solutions generated CO_2 by action on the carbonates of the gangue. M. de Bavay would not allow the latter argument and in order to prove to himself that CO_2 was not generated, he performed the following experiment in his own laboratory. A small quantity of ground pulp was submitted to treatment by carbonic acid gas in order to remove all trace of carbonates. The intention was subsequently to treat the residue with acid solution in order to prove the chemist's contention. However, the intention was forgotten *ad interim* when a surprising result—one of those accidental discoveries so often seen when a different object is in view—occurred. "When the contents of the receptacle were emptied into a beaker, a thick clean layer of 'black jack' sprang to the surface of the liquid, while the white clean gangue was precipitated to the bottom." Those are essentially M. de Bavay's descriptive words, to me, on his discovery. He commented: "Well, I knew if I could put that into practical application I had a pretty good thing." So he developed a flotation process with carbonic acid as the essential reagent, and later the first de Bavay plant at the North mine, Broken Hill, was established on those lines! Commercially it was a failure, and when in 1907 I commenced pulling down the retorts, the old man was quite affected; but as the space was required, they had to go. He had substituted the 'universal' combination of acid and oil, and had his patents with the rest. His way of treatment varies from the others—they all vary a little—but acid and oil are the essentials, and the Judge who has the decision of "who has prior rights to a patent in a flotation process" has my sympathy. So much is problematical. Delprat—whose experiments were practically contemporary with those of Potter, but quite independent—won the suit in the Civil Court. Delprat had gone further than Potter and established a commercial process. Potter had not gone beyond the laboratory. Potter appealed to the High Court, however, and the Broken Hill Proprietary company settled the case by payment to the Potter Treatment Co. of £10,000 and forming an amalgamation between the companies negotiating both patents.

The Potter company successfully defended an objection to amendments in reference to their patents by the Minerals Separation, Ltd., in June, 1909, before the High Court of Australia; and the Potter patents are duly recognized and established in Australia. Unfortunately the inventor—as is also usual—got nothing out of all his work, worry, and brain power. Charles V. Potter was still a poor man, when he died, no doubt poorer both financially and spiritually than prior to his great invention.

However, in this world a man who invents a process is 'looking for trouble' and when, not having engineering knowledge of his own, he persists in doing the engineering development of his chemical results, he is making trouble both for himself and his backers. The astonishing thing is that these latter, generally hard astute business men, allow such a course. To hark back to the de Bavay 'movement.' It took quite three years, and an expenditure of about £80,000 (the company admitted £65,000) to get through the experimental stages. And



THE PORT PIRIE SMELTER, SOUTH AUSTRALIA.

it was only when the inventor was 'put aside' and the management allowed to 'get to work' that success—so obvious so much earlier to engineers—was achieved. Further, the 'tables' that were finally adopted 'cone-shaped' were condemned by the inventor in 1907. This is an amusing point to me, for I tried so hard to introduce the 'cone tables,' to overcome the absurd system of mechanical beaters then in use, that would not run a day without breaking down. The principles of de Bavay's process are

1. Friction to clean mechanically the particles of mineral, particularly in weathered material.

2. Treatment with sulphuric acid with heavy agitation to remove the oxidation skin.

3. Subsequent double washing, with agitation, to remove insoluble sulphates resulting from acid treatment.

4. Oiling with agitation, so that all mineral particles obtain a film of oil on their entire surfaces.

5. Aeration, partly in an agitator with oil, and subsequently by 'beaters' and on transit over tables (now conical and corrugated) in a thin pulp-flow with water.

6. Increase of surface tension by addition of a small quantity of emulsified oil (colza oil used to be employed), water-borne, just prior to the pulp flowing onto the tables. The concentrate floats over on the overflow of spitz-boxes, into which the tables dip. A series of four tables is sufficient to 'clean' the tailing.

The process is 'tedious' but it is a true flotation, involving no frothing, and no uplifting gas-bubbles as in the Potter and other methods. I understand de Bavay patents are now combined with those of the Minerals Separation and T. J. Hoover, in his excellent work on the subject ('Concentrating Ores by Flotation,' 1912) prophesies that not much will be heard of it in future.

Personally, I have a great regard for this process, used judicially and perhaps in combination with other methods. The great advantage is the high grade of the concentrate. This is all important where shipment of the product is essential, a large saving in freight being effected. The Amalgamated Zinc Co.'s concentrates assay up to 48.5% zinc quite regularly and in 1907 I shipped parcels of 48.9 and 49.1% zinc. The disadvantages are increased cost of operation, and the fact that slime is not amenable to this process, so far as trials have gone.

Slime is the mill-man's *bete noir* in all operations of concentration. For chemical processes they are 'the thing.' Perhaps a combination of flotation and lixiviation may be the future 'way out.'

In conclusion a few remarks on 'oils' may be of advantage. Much has been written on the use and efficacy of oils, but, even at the risk of being considered 'heathen,' I am emphatically of opinion that any particular oil for each particular ore is 'bunkum'! Oil is a means to the end, not the end. At the North Mine plant expensive 'valve' oil was used, costing about 90c. per gallon, and three months later 'truck' oil at 25c. per gallon gave equally good results! Both the above were mineral oils, but subsequently crude 'eucalyptus' oil (distilled) from the leaves of the indigenous eucalyptus (those wonderful trees that supply the strongest constructional timber in the world) has been used in Australia with great success. Refined eucalyptus oil—used medicinally with good effect for strains, rheumatism etc, and internally for colds—is expensive. But I judge crude eucalyptus oil for flotation processes could be imported quite cheaply from Australia, if the demand was sufficient. However, with proper judgment, good plant design, and legitimate experiment, I consider that success can be obtained in most cases in the treatment of sulphide ores without any great worry as to the kind of oil to be employed.

Manjack

In outward form and general appearance manjack is not unlike fine coal and is essentially a bituminous substance. It is an oil residuum occurring in lenticular seams between walls of peculiar clay, which appear to have absorbed the oil under very heavy pressure. It is jet black in color and resinous in its nature and has long been known for its insulating properties in the manufacture of electric coils, dynamos, and generators. In the island of Trinidad there are large deposits of manjack, especially in the San Fernando district, where are the Vistabella and the Marabella properties. During the past decade 18,000 tons was exported in a crude state.

The Vistabella manjack properties are worked under a long lease by an American company, which, besides exploiting and exporting manjack in its natural state, has undertaken the manufacture of certain well-defined compounds. One of these is a high-grade black manjack paint for use on smokestacks and on boilers, both inside and out; another is a preparation suitable for greasing pipe-threads, dressing wire-rope, etc.

Chester W. Martin, U. S. Consul at Georgetown, submitted in 1913 a lengthy report on the mineral resources of Barbados, British West Indies, in the course of which he said, relative to manjack:

"Manjack has been known to exist in the island almost from the first settlement, and a governor's report, dated 1676, states: 'There is a kind of metal much resembling cannel coal in Lancashire, called 'moniak,' with which sugar is boiled.' The surface outcrops have been frequently dug and used as fuel on sugar estates in the district in which it is found, but no systematic attempt was made to mine it until 1895. Starting with the idea of mining a cheap fuel, those so engaged were not long in finding that some of the mineral sold to the railway company as fuel was an almost pure bitumen of great value to the paint and varnish trades. Since that time the working of the mines has been continuous to the extent of supplying the demand for export.

"Barbados manjack is of two varieties, the conchoidal and the columnar. The first is the more valuable, and a newly fractured specimen cannot be distinguished from jet, so far as outward appearance is concerned."

The cargoes of manjack invoiced at the Georgetown consulate for shipment to the United States in 1914 amounted to 59 tons, with a declared value of $6159, against 112 tons, valued at $9435, in 1913.—*Daily Commerce Reports.*

Notes on Homestake Metallurgy

By ALLAN J. CLARK

*Introductory. The mineralized slate and schist that constitute the ore vary considerably in composition, but the unoxidized ore, constituting the major part of the reserves, contains either chlorite or hornblende, with quartz, carbonates of lime, magnesia and iron, and arsenopyrite, pyrite, and pyrrhotite. Ferrous minerals predominate and this fact has been an important factor in determining the metallurgical treatment.

With one or two exceptions the minerals noted are of relatively high specific gravity, and the ore as a whole is exceptionally heavy, many determinations giving an average specific gravity of 3. This high specific gravity presents one decided advantage, when the cost of treatment is compared with operations elsewhere, in that the ton, almost universally the basic unit, represents a volume probably less by 10% than that of many gold ores. On the other hand, this high gravity renders more difficult the discharge of pulp from mortars, its distribution on amalgam tables, and its transportation in launders.

In the same way, as attesting the usual balance of such variations of different ores, it may be noted that the needlelike fibres of hornblende (cummingtonite), interlacing throughout the mass, render the ore more difficult to crush, but on the other hand assist in maintaining free leaching in both sand and slime treatment, retaining their characteristic form as far as they can be traced with the microscope.

The metallurgical equipment consists of:

At the South Side:
- 3 stamp-mills (660 stamps) with 36,356 sq. ft. of amalgam plates.
- 1 re-grinding plant, with independent cone system and 540 sq. ft. of amalgam plates.
- 4 batteries of cones for classification.
- 3 clarifying-tank houses.
- 1 sand-plant.

At the North Side:
- 2 stamp-mills (360 stamps).
- 2 tank-houses.
- 2 cone-houses.
- 1 sand-plant.

At Deadwood:
- 1 slime-plant, treating the combined slime from South and North sides.

A flow-sheet is given in Fig. 1.

The ore supplied to the North Side mills is usually drawn from the upper levels of the mine, and is at least partly oxidized. It is more easily penetrated by cyanide solutions than is the unoxidized ore, and satisfactory extractions are at present made from the sandy portion of the mill-tailing without further reduction in tube-mills.

*Abstract from paper to be presented at the September meeting of the American Institute of Mining Engineers, San Francisco.

Stamp-Milling. The stamps, when newly shod, weigh 900 lb. and drop 10 in., making 88 drops per minute. Pulp discharges through No. 8 diagonal needle-slot screens. Inside amalgamation is practised, quicksilver being fed to the mortar, and a copper chuck-bolt, about 5½ in. wide, being placed inside the mortar, below the screen. To facilitate discharge and distribution of the pulp over the amalgam plates, water is liberally used, the usual ratio being from 10 to 11 parts, by weight, to one of solids.

Electric drive, now in use for more than two years,

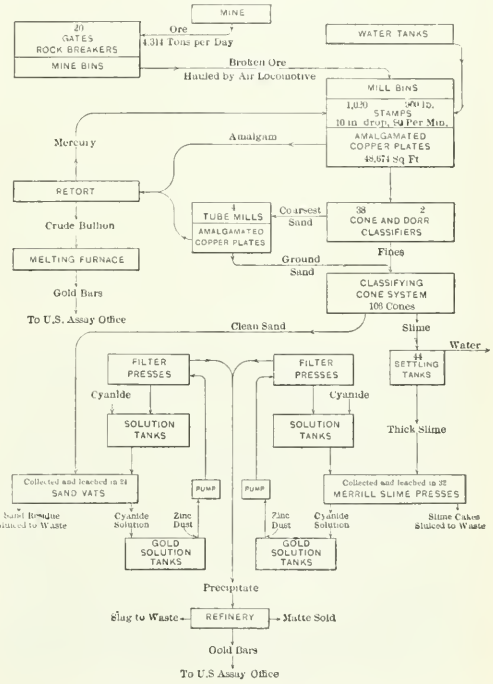


Fig. 1. Flow-sheet of Homestake Mill.

permits more nearly continuous operation than formerly. A 25-hp. back-geared motor drives each 10 stamps, transmitting motion by a 16-in. belt.

Chuck-blocks are cleaned in rotation, the usual interval between cleanings being about two weeks; outside plates, except those of the fourth row, are cleaned and dressed daily. Fourth-row plates are dressed at intervals of two days. At the foot of the rows of plates are traps, from which the sand is removed every second or third day. This trap-sand is run over a special silvered amalgam plate, the tailing rejoining the main stream of tailing. It was formerly the practice to clean these traps

daily, but this is not necessary since the development of the re-grinding plant, which acts, in effect, as a large trap for all the mills.

Amalgam is retorted three times each month. Oil-fired retorts are used, the resulting bullion being melted in coke-fired furnaces. The loss of quicksilver in retorting is almost *nil;* the subsequent melting loss, which averages slightly more than 1% of the weight of the crude bullion, includes some quicksilver not driven off in the retorts.

The unoxidized ore, although carrying large quantities of sulphides, amalgamates well, but not so freely as old records show to have been the case in earlier years, when less of this class of ore came to the mills. A longer time is apparently required to properly incorporate the quicksilver with the pulp, and the resulting amalgam is recovered somewhat farther from the battery. The results given in Table I illustrate this tendency.

TABLE I.—COMPARISON OF AMALGAMATION RESULTS ON ORES OF DIFFERENT PERCENTAGES OF SULPHIDES

Column I. All mills, three-month period in 1910.

Column II. One mill, crushing unoxidized ore exclusively, three months, 1915.

Of the total extraction by amalgamation, there was recovered from:	I. %	Cumulative. %	II. %	Cumulative. %
Batteries	49.4	49.4	35.6	35.6
First-row plates	37.5	86.9	42.9	78.5
Second-row plates	4.4	91.3	8.1	86.6
Third-row plates	2.3	93.6	3.5	90.1
*Fourth-row plates	0.9	94.5	2.0	92.1
Skimmings	4.0	98.5	6.9	99.0
Trap-sand	1.5	100.0	1.0	100.0
Percentage of ore-value..	...	71.7	...	69.7

*Only two mills (440 stamps) equipped with a fourth row of plates.

The 'skimmings' are recovered from re-treatment of the foul amalgam, sulphide particles, etc., removed from the clean-up sink during the clean-up of the chuck-block and plate amalgam.

These cleanings are re-treated with an excess of mercury in a small barrel 24 in. diam. by 302 in. long, in which iron balls or pebbles are placed, the mineral particles being ground and the amalgam recovered. The rejected sulphides, carrying perhaps $1000 per ton in gold, are briquetted with water-glass and charged to the blast-furnace, when smelting cyanide precipitate or by-products.

The increased proportion of the amalgam recovered from the skimmings during the second period under review is a natural result of the increased percentage of sulphide particles in the ore. The tendency of fine sulphides to collect in the slight depressions in the surface of an amalgamated plate is well illustrated at the re-grinding mill, where it is necessary to wash such a film from the surface several times each day.

It is perhaps not customary to report inquiries that have failed of definite conclusions. The following notes of such an investigation are not without interest, despite the lack of decisive result. Records of all six mills were tabulated over a period of one year, in an effort to determine what relation, if any, existed between the amount of quicksilver fed to the batteries, the amount of bullion recovered, and the grade of the ore crushed. As was to be expected, individual determinations varied considerably from the average, but for four of the mills, and these fortunately including those crushing ore of the two extremes in value, the points coincide reasonably well with a curve represented by the equation

$$T = \frac{8.5\,B\text{-}H}{H}$$

when

T = Value of ore (dollars per ton).

H = Troy ounces of quicksilver fed to batteries.

B = Troy ounces crude bullion ($16 per oz.) recovered.

Of the two remaining mills, one was crushing surface ores with comparatively coarse particles of free gold. This, not unreasonably, showed values for H about 10% below the values indicated by the equation. The sixth mill gave results nearly 20% higher than might have been expected. This mill, on account of an insufficient supply of water, crushed nearly 10% less ore than the average, and it is conceivable that the longer retention of the material in the battery caused undue flouring of the quicksilver. It is more probable, however, that the explanation is to be found in the personal equation of the millman in charge.

The crushing units are not in conformity with modern ideas, and there is no doubt that, were the plants to be built anew, radical changes in design would be made. The Homestake, unlike many younger mines, has developed gradually from comparatively small beginnings. The mills represent the growth of 30 years. Built before the cyanide process was known, they then represented advanced milling practice. It must be conceded that the stamp duty of 4½ tons, with 80% of the tailing passing a 100-mesh screen and 60% passing a 200-mesh screen, is fairly good even when compared with the results reported from many newer installations.

We find that heavier stamps crush more rock, with little or no change in the sizing of the tailing unless more open screens are used; in which case, even without increasing the falling weight, tonnage may be gained at the sacrifice of fineness. To us it appears that compactness of plant, with the saving both in first cost and, later, in labor and supervision, constitutes the leading claim of the heavy stamp for preferment. Indeed, if the gold metallurgist is ready to dispense with amalgamation—and we are by no means prepared to do this—it is more than probable that he will do well to investigate the crushing practice of modern copper-mills before he commits himself to the heavy gravity-stamp. Alaska, at the moment, holds more of interest than does Africa.

It may be pertinent to note that I have never encountered a Homestake mill-tailing, no matter how far advanced in secondary treatment, from which some free gold could not be recovered by laboratory amalgamation tests.

RE-GRINDING. Operations at the re-grinding plant offer little of interest, the practice conforming closely to the usual methods.

The feed to the tube-mill is already so fine (only 25% remains on a 50-mesh screen) that the efficiency of the mills is low. The critical size of sand delivered to the sand-plants is about 100 mesh for unoxidized ore, and 80 mesh for oxidized. It is advantageous to operate the mills in closed circuit, but it is difficult to do this without permitting sulphide particles that have been sufficiently reduced in size to remain in the circuit. By introducing a double baffle or trough-classifier, containing a hydraulic device, into the slime-overflow end of a Dorr classifier this difficulty has been in a measure overcome, and two of the mills are at present using this system. The accompanying table of tube-mill data has been compiled from earlier records, when none of the tube-mill discharge was returned for further grinding.

THE HOMESTAKE MILLS, AT LEAD, SOUTH DAKOTA.

Each mill discharges its tailing over an amalgam table, and about 40 cents is recovered per ton ground.

RE-GRINDING PLANT DATA

Mill number	1	2	3	4
Manufacturer	Denver Eng. Works	Allis-Chalmers Co.	Allis-Chalmers Co.	Hardinge Conical Mill Co.
Dimensions, feet	5 by 14	5 by 18	5 by 18	6 by 6
Speed, rev. per min.	27.0	28.5	28.0	26.5
Actual horse-power (motor input)	32.0	42.0	42.0	27.0
Fed from	Dewatering cone	Dorr classifier	Dorr classifier	Dewatering cone
Tons fed per day	98.0	138.0	133.0	93.0
Pebbles per ton	1.40	1.24	1.38	1.71
Tons to pass 100 mesh	41.0	52.0	49.0	34.0
Tons to pass 100 mesh per horse-power	1.28	1.24	1.17	1.26

RE-GRINDING PLANT OPERATING COSTS FOR 1914

	Cost per ton fed to tube-mills.	Cost per ton reduced to pass 100-mesh sieve.
Labor	$0.0496	$0.1289
Pebbles and liners	0.0259	0.0673
Renewals, mills, and cones	0.0074	0.0193
Machine-shop service	0.0037	0.0096
Silver-plating	0.0077	0.0200
Sundries	0.0029	0.0075
Power	0.0292	0.0759
Total	$0.1264	$0.3285

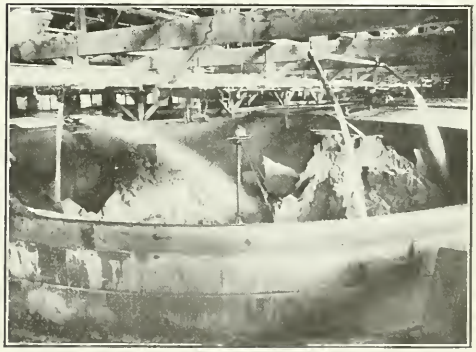
Tons fed to mills, 152,106. Tons ground to pass 100-mesh sieve, 58,605. Cost of re-grinding, per ton crushed in stamp-mills, $0.0121.

SAND-TREATMENT. The sand is leached with cyanide solution in vats 44 ft. diam. by 9 ft. deep, holding 610 tons of sand each. The operations are distinguished by unusual care in the preparation of the material for extraction, rather than in the extraction itself.

Classification and aeration are the two essentials to successful work. The latter, necessary to overcome the tendency of the ferrous compounds in the ore to remove the vital oxygen from the solutions, is achieved by forcing, at intervals, air under slight pressure into the false bottom, below the filter-canvas. The charge is suitably drained before this air is applied; the pressure is so adjusted that the air is forced into the sand, yet is so low that the column of sand is nowhere broken or disturbed. To secure this immunity thorough classification is essential, and this has always been recognized as a matter of first importance.

Four batteries of cones, each fed from the discharge of the preceding set, the first three sets acting by gravity alone, the last assisted by a hydraulic connection, deliver a clean sand to the vats. As a further precaution, the vat is filled with water before sand is turned into it, so that a constant overflow is maintained during filling and a final separation of slime particles added to the sum of the cone separations. As a matter of fact, the sand is so clean when it enters the vat that this final step is not one of strict necessity, but we have found that a charge filled in this manner is in a less compacted condition, presumably easier to leach and certainly easier to discharge.

The action of the air is interesting. Laboratory tests



SLUICING THE BIG SAND-VATS.

indicate that, on an average, about 75 cu. ft. of oxygen is absorbed by a ton of ore, before its reducing action is corrected. If this air is not supplied from some extraneous source, the solutions are vitiated and extraction ceases. When air is applied and is followed by a water wash, calcium thiosulphate appears in the effluent solutions; when the air is followed by cyanide, the effluents contain sulphocyanides and free cyanide appears only after some time. After a limited time of leaching, the extractive power of the solution decreases and further aeration of the charge is necessary. Each aeration is

attended by the formation of some acid and the consequent destruction of some lime and cyanide. After treatment, the sand shows no sign of oxidation; neither analytical nor microscopic examination can detect difference between charge and residue.

Lime, crushed in a one-stamp mill to pass a 7-mesh screen, is added to the pulp stream as it flows to the vat. Regulation is by weighing a prescribed amount of lime into the automatic stamp feeder at 2-hr. intervals. The choice of screen is determined by the rate at which the lime slakes, the intent being to exhaust the particles only when treatment is completed. Formerly small quantities of lime were added to the top of charges during the drainage periods, to supplement that fed with the sand, but this is no longer considered to be necessary and is not done except in emergencies.

It had long been recognized that a high protective alkalinity was detrimental, but until within the past two years it had been tacitly accepted that it would be impossible to dispense entirely with protective alkali. Eventually this was done; extractions improved and consumption of cyanide was materially reduced.

The gratifying results are in a measure due to another change in procedure, initiated at about the same time. Reference to the treatment chart will show that solutions of two strengths are used; that stronger in cyanide is used earliest in the treatment of a charge. When these solutions appear as effluents, one portion is precipitated, the other brought to full working strength by adding cyanide and thereafter returned to the extraction of another charge of sand.

This custom is by no means unusual, yet wherever it is used the procedure seems to be to maintain the stronger solution at a fixed content of cyanide and to allow the weaker to vary in strength according as the varying losses in treatment may determine. This is wrong in principle. The critical strength is that below which the weaker solution will no longer dissolve its quota of gold, or, if dissolving it, will no longer freely yield it to precipitation. If the strength is greater than this, we may confidently expect some cyanide to be destroyed without giving compensatory service. In such circumstances, if the maximum working strength is reduced, the weaker solution will be automatically restored to the lowest economic strength; if it falls below this, a temporary increase in the maximum strength will restore it. In other words, cyanide should be added to the *strong* solution in accord with the determinations of strength made on the *weak* solutions. Thus, operating with a strong solution of variable strength and a weak solution also variable, but never far from its effective limit, it may be anticipated that little cyanide will be needlessly expended in this way.

Slime-Treatment. The slime-plant is equipped with 30 Merrill presses, each of 90 frames, 4 by 6 ft. by 4 in. One press holds 26 tons of slime, and has a capacity of about 70 tons a day.

The entire treatment is given in the presses, which successfully meet the conditions for which they were designed, holding a tight and homogeneous cake during aeration periods (which impose a most exacting requirement on the machine) and discharging readily without requiring manual labor. In this connection it may be mentioned that all the operations incident to the filling, aeration, leaching, washing, and discharging of 30 presses—totaling about 75 charges daily—are conducted by three men on each shift. The actual time required by one of these men in the performance of every step in the treatment of a charge is slightly less than 15 minutes.

Treatment is in principle identical with that of the sand, periods of aeration and treatment alternating with sufficient frequency to maintain the activity of the solutions. The alkalinity is carried at a very low point, but the working solutions are of low cyanide strength, as reference to the charts will show. Within the restrictions imposed by practice, there seems to be no solution so weak that it will not freely extract gold from the aerated slime. The problem seems to demand the passing of a definite volume of solution through the slime-cake, rather than treating with solution of a definite strength or for a definite time. So long as this amount of solution is passed, the extraction is accomplished. Thus the treatment time is a function of the leaching rate.

The minimum working strength is determined by our ability to precipitate the effluent solution, and in developing this minimum much of the treatment is given with very dilute solutions, with the result that the consumption of cyanide has been reduced to an extremely low figure. For instance, a 10-day period, concluding as this is written, gives the sodium cyanide (128%) consumed per ton of slime treated: In treatment, 0.127; added for precipitation, 0.008; making a total of only 0.135 pound.

The precipitation of the 'low solution' (first and final effluents, low in both gold and cyanide) is difficult; doubly so on account of the low alkalinity; and after trial of many expedients to assist it we are not able to improve upon Carter's old system of a drip of strong solution.

This, usually added with the feed of zinc-dust at the rate of 1 lb. per hour (or per 25 tons of solution precipitated) constitutes from 5 to 10% of the cyanide used. An excessive amount of zinc-dust is also necessary to insure clean precipitation of these solutions, and this entails further expense, not merely in the first cost of the zinc, but in the refining of the larger bulk of low-grade precipitate. Combined, these costs consume about 25% of the profit won through the reduction of cyanide consumption, a satisfactory enough result in a plant where treatment methods have been so well established as is the case here, even though the impression may be conveyed that one branch of the work has lost efficiency.

Some assistance in this precipitation difficulty is received through the application of this barren low solution as a preliminary wash.

Double cloths are used on the presses, the lighter one being in contact with the frame. This is unbleached muslin twill, and is in turn covered with cloth of No. 10 canvas duck. Joints are made with Thermalite paint.

During the early days of the plant, when the equip-

ment was not equal in capacity to the tonnage of available slime, a suit of cloths was used for as much as 30 months, it being preferable to lose slime rather than to stop to repair leaks. It should be remembered that the arrangements of ports and channels in the presses is such that treatment may be given in either direction, so that a single leak would in no wise affect treatment, but would merely entail the wasting from the plant of a certain amount of untreated slime. At this time, as much as 500 tons was wasted in a month. As the plant has been brought to full capacity, the cloths have been renewed, first after 18 months' service, now after 16 months'; the leakage loss on the latter basis has been brought to an average of less than 40 tons monthly over an entire year, with a minimum of 8 tons in a single month. This in treating a total output tonnage of more than 58,000 tons of pulp.

Precipitation. The Merrill system of precipitation with zinc-dust is used at all cyanide plants, as is the Merrill filter-press of triangular section. This method has been fully discussed,* and the technique remains about as there described. It has been mentioned that the effect of the recent variations in treatment has been adverse to precipitation, since the tonnage of solution requiring precipitation has been increased at the same time that the content of solution in gold and cyanide has been reduced. Beyond the natural effects—increased zinc consumption and lower-grade precipitate—no difficulties have been encountered.

Double cloths are used on the frames, the outer one being taken off when the press is cleaned and replaced by the inner cloth, which is in turn replaced by a new cloth. The outer cloth is burned, the ash going to refining. Experiments are still in progress to find the lightest and cheapest cloth that can be used for this purpose without unduly increasing the hazard of leakage. All washing of cloths is eliminated by this system. Against the added cost of cloth may be set the advantage of security from leaks due to rotten or wrinkled cloths and the labor of washing soiled cloths.

Refining. In its essentials, this remains as described in the earlier paper, except that after acid treatment of the lower-grade precipitate, the briquettes are charged to the blast-furnace instead of being fused in the cupel. The latter treatment is still the standard for precipitate of higher grade.

Acid-treatment is a preliminary to furnace-treatment of all precipitates. It may not be necessary, but in my judgment it is sound metallurgy, since it enhances security from stack losses and insures more fluid slags. Moreover, the decreased bulk of product to be smelted with lead decreases the time required for that operation, always more or less hazardous to the health of the workmen.

Oil is now used as a fuel in the cupel furnace, replacing wood. It is an ideal fuel for the purpose, and its use has resulted in an acceleration of nearly 50% in the rate of cupeling.

*Trans. Inst. M. & M. Vol. XXII, page 68.

Flotation at Broken Hill

According to the annual report of the Zinc Corporation, recently issued, the following results were obtained: Operations were suspended for four months owing to the War. The company treats tailing from other mining companies, also ore from its own mine, the South Blocks.

The lead concentrator treated 141,667 tons of ore of an average assay-value of 14.4% lead, 2.6 oz. silver, and 9.3% zinc. This produced 26,567 tons of lead concentrate assaying 64.6% lead, 9.2 oz. silver, and 6.45% zinc; and 34,317 tons of zinc middling assaying 15.8% zinc, 1.6 oz. silver, and 4.9% lead. The cost at this plant was $1.13 per ton.

The zinc concentrator treated 221,620 tons of tailings assaying 13.68% zinc, 6.42 oz. silver, and 5.93% lead. Of this, 169,180 tons was from dumps, the remainder being ore from the British and Junction mines, and the company's own lead concentrator mentioned above. This yielded 63,300 tons of flotation concentrate assaying 43.96% zinc, 13.91 oz. silver, and 13% lead. The retreatment of this product, by tabling and the Horwood process combined, yielded

	Tons.	Zinc, %	Silver, oz.	Lead, %
Zinc concentrate	48,325	46.77	10.58	7.64
Horwood zinc concentrate	3,986	48.17	15.16	6.47
Lead concentrate	7,469	15.69	32.84	54.56
Horwood lead concentrate	1,688	14.63	38.01	35.48

In addition to the above, 1362 tons of zinc slime was produced, assaying 37% zinc, 18.42 oz. silver, and 13.43% lead.

The Horwood process plant treated 6144 tons of zinc slime direct from the zinc concentrator and 3169 tons from the accumulated dumps for a return of

	Tons.	Zinc, %	Silver, oz.	Lead, %
Zinc concentrate	5,882	48.1	16.90	6.80
Lead concentrate	2,619	14.0	40.52	35.55

The cost at this plant was 30 cents per ton. The enhancement in profit due to treatment by the Horwood process amounted to $1.72 per ton of zinc slime.

The sulphuric acid plant worked steadily at full capacity and made 2914 tons of acid. Working costs averaged $2.50 per ton, the Horwood* process being responsible for 30c. per ton of this total. The estimated amount in the dumps still remaining to be treated is 1,522,074 tons.

Material dredged at Panama in May amounted to 1,092,637 cu. yd. Of this, 671,149 yd. was from the Gaillard (Culebra) cut.

*The principle of the Horwood process, according to Hoover, in 'Concentrating Ores by Flotation,' is that when a mixture of iron, copper, lead, and zinc sulphides is roasted, the surfaces of the particles of the three former sulphides are changed to oxide and sulphate at a comparatively low temperature, whereas the zinc sulphide is practically unaltered. The partly-roasted material is then subjected to a heated-acid oil-flotation process, when the zinc sulphides will float away, and the deadened or sulphated compounds of iron and lead will sink with the gangue.

A Mine-Owning Tribe of Indians

By LUCIUS L. WITTICH

Members of the Quapaw tribe of Indians in Ottawa county, northeastern Oklahoma, are, almost to a man—and squaw also—firm believers that "a bird in the hand is worth two in the bush," which explains the recent decision of the Supreme Court of the United States, which has decreed that the Quapaws shall no longer have the privilege of selling their royalty rights on the zinc and lead lands they own.

About ten years ago zinc and lead ores were found in abundance on the Indian tracts and since then some of the most productive mines in the entire Missouri-Kansas-Oklahoma district have been developed on these lands. In this district there are about 24 different camps, producing in all about $18,000,000 worth of ore annually, and it is interesting to note that the northeastern Oklahoma district now ranks third among the list of producers with a yearly ore output valued at $2,000,000. By an act of Congress in 1897 the Indians were permitted to lease their lands for mining purposes for a period of 10 years, but at that time no mines of importance had been opened. It was about eight years later that the first big mines were developed north of Miami, Oklahoma. The operators would procure leases from the Indians, agreeing to give them 5% of the money received from the sale of ore; at this juncture the speculator would appear upon the scene and purchase the Indian's right to whatever royalty money might accrue. The assignment of such royalties would be duly printed in legal form in some newspaper and presumably the transaction was in accordance with law.

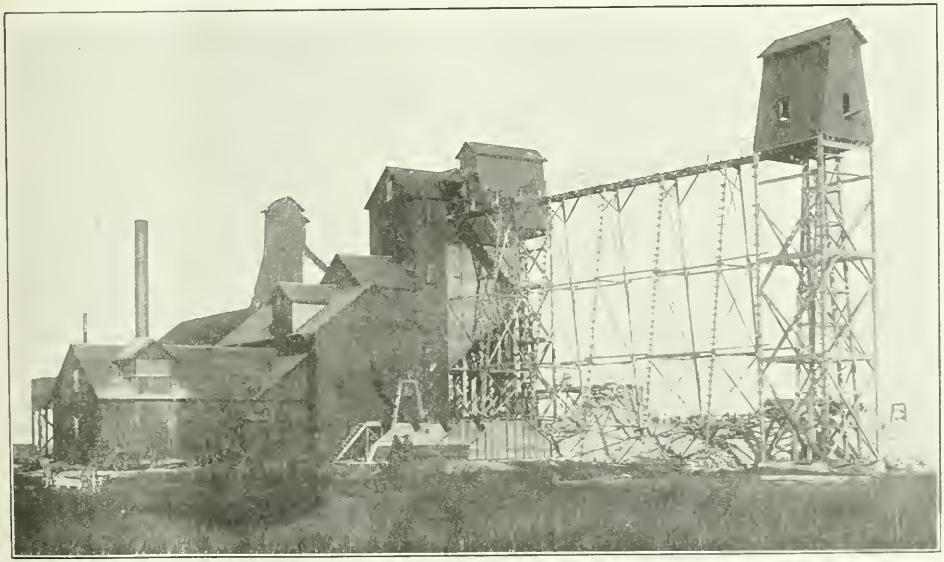
In the early days of royalty-selling the Indian's right would be transferred for an absurdly small sum. When a speculator learned that a rich drill-strike had been made on a certain piece of land he would go to the Indian land-owner and endeavor to show him—and usually with success—wherein he could be benefited by disposing of an uncertainty for a certainty, the latter being some specified sum of money, usually not more than two or three hundred dollars, and sometimes as low as $25. As an illustration, a state official of Oklahoma, some years ago, purchased for $250 the royalty rights on the land of Wah-tah-noh-zhe, a squaw, the lease of which land was held by the Miami Royalty Co., which had agreed to give the squaw a 5% royalty. By the assignment of the royalty rights the proceeds would go to the state official instead of to Wah-tah-noh-zhe, but to the latter the $250 in hand was a much safer bet than the slim chance of ever getting such a vast sum out of the mineral that might be produced from her property. Besides, that was in the early days of development and big mines were yet to be a thing of the future. But it chanced that on Wah-tah-noh-zhe's land the famous Turkey Fat mine was opened and the royalty already received by the Oklahoma politician who purchased the squaw's royalty rights has exceeded $100,000. By the recent decision of the Supreme Court, which reversed the decision of the lower courts, Wah-tah-noh-zhe will not only be entitled to the royalties henceforth—and the Turkey Fat is still a big producer—but the way is opened to her to bring suit for the recovery of the royalties paid over to the Oklahoman during the past several years.

Scores of similar instances, on a smaller scale, might be mentioned. In the more recent transactions, however, the price of the royalty assignment has begun to grow. Meh-hunk-a-zhe-ka Beaver, a squaw, sold for $1200 to a speculator at Baxter Springs, Kansas, her royalty rights on the land where the Ortt & Buchanan Mining Co. is now opening a large lead-producing property. Meh-hunk-a-zhe-ka Beaver received her $1200 in cold cash and possibly has spent it by this time. Just where the purchaser of the royalty rights gets a run for his money in this instance it is hard to determine, as he had not yet begun to receive the royalties that he had purchased when the Supreme Court's decision knocked his cleverly-laid plans into a cocked hat. Will Meh-hunk-a-zhe-ka Beaver be required to return the $1200? The purchaser of her royalty rights is worrying more about the answer to this question than anyone else.

The Quapaws are the most uncivilized and the wealthiest Indians in Oklahoma; yet they are the only tribe of Indians in the United States who do not have to submit to the Secretary of the Interior, for his approval, their plans for the disposal of their land. This condition was the result of a lobby at Washington lead by ex-Governor Crawford, of Kansas. He was aided financially by A. B. Abrams, of Baxter Springs, a homeless New York Indian with a Jewish ancestry. Abrams has succeeded in gathering unto himself and relatives 1700 acres of valuable land in north-eastern Oklahoma and is now secretary of the Quapaw tribe. One of the rewards of ex-Governor Crawford's efforts at Washington was his acquisition of 160 acres at Lincolnville, Oklahoma, on which the famous Omaha-Petersburg mine was located.

The allotment of Quapaw lands was made in 1896, each adult allottee receiving 240 acres. Although most of the land was highly productive the members of the Quapaw tribe, not more than 500 in number, gave little attention to its cultivation. Many of these Indians are almost what might be termed 'blanket Indians' and their homes consist of rude huts in the backwoods. They lack every vestige of ability to promote the development of their rich mineral lands, and, instead of being able to go forth and organize mining companies on their own responsibility and share in the greater profits to which they are entitled, they are content with receiving a mere pittance, comparatively speaking, although in reality the royalties they are receiving aggregate a good many thousands of dollars each month. They are willing to

QUAPAW INDIANS OF NORTH-EASTERN OKLAHOMA. MANY IN THIS GROUP ARE OWNERS OF RICH ZINC AND LEAD TRACTS, THE ROYALTIES FROM WHICH MAKE THEM INDEPENDENTLY WEALTHY.



THE CORNFIELD MINE. A ZINC-LEAD PRODUCER IN OKLAHOMA. THE INDIAN LAND-OWNER OF THIS MINE PREFERRED CASH IN HAND TO FUTURE ROYALTIES.

lease their lands at 5% and would still be willing to take a cash settlement of a few hundred dollars rather than take their chances on getting thousands or hundreds of thousands of dollars in royalties later on; but Uncle Sam has awakened to the necessity of protecting them to some extent at least. Oftentimes the lessees who procure the lands at 5% royalty sub-lease the same properties out for 10, 15, or even as high as 40% royalty where the ore is rich, and while the actual land-owner is thus receiving a meager 5% return, the middle-man, or first lessee, who really does no actual mining himself but who encourages others to mine, sits back at his leisure and rakes in his big royalties, frequently getting independently wealthy in the course of a year or so.

In Ottawa county there are seven other Indian tribes, but so far the Quapaws have been the only ones fortunate enough to own mineral-producing lands. The Cornfield mine, shown in an accompanying illustration, is a new producer of importance on the land of Benjamin Quapaw, who assigned his royalties to a Kansas speculator. Harry Crawfish sold, for a song, his royalty rights on the lease north of Miami where the Picher Lead Co. has opened one of the most productive zinc-lead mines in that district. Julia Greenback owns the land on which the Lost Trail mine is situated. She, likewise, disposed of her royalty rights for a few hundred dollars, whereas, by waiting, she would have received something like $15,000 in royalties.

Leaching at Yerington

Some months ago the General Development Co. was induced to undertake extensive drill exploration at the Copper Flat property, two miles west of Yerington, Nevada. The work was in charge of Louis F. Wright, of the General Development Co.'s staff. About 700,000 tons of 2½% ore was developed on a part of the ground and enough work was done to justify a total estimate of 2,000,000 tons of ore, all oxidized. The Walker River Copper Co. has been incorporated in Nevada to undertake the work of exploration.

The laboratory work in developing a process to treat the ore was done in the plant of the Midland Ores & Patents Co., at Waverly, New Jersey, and the results have been satisfactory enough to justify the drafting of plans for a 400-ton mill. The proposed process is comparatively simple and economical. The ore will be treated with an acidulated solution of ferric chloride containing sodium chloride. The copper will be precipitated on granulated iron in tumbling-barrels in the usual way, the resulting ferrous chloride will be regenerated to ferric salt by the electrolytic deposition of sufficient metallic iron to liberate the requisite amount of chlorine. The economy of the process lies in part in the regeneration by electricity of the spent solution and the recovery of the excess iron, permitting the repeated use of both without material loss. At the one-ton plant of the Midland company, it has been found possible to use the solution as many as 14 times and it was still in good condition for further use. Test-runs have been made on many different oxidized silicious copper ores and from those at all adapted to the method, a recovery of 90% has been usual.

A solution containing 3% ferric chloride and 5% salt has proved an effective solvent with most ores. The amount of iron entering the solution in the copper precipitating step is theoretically 50% in excess of the amount separating in the ore treatment when the copper dissolves. The acid required is the amount necessary to re-dissolve such iron as may separate by reason of oxidation or basic reactions.

In the regeneration an efficiency of 95% has been obtained at the anodes and 75% at the cathodes. The current strength is 3 to 4 volts and current density 4 to 6 amperes per square foot. The deposited iron is used to precipitate the copper, with a corresponding reduction in the amount of scrap-iron.

The reactions incident to the several steps are as follows:

Ore treatment

$$3CuO + 2FeCl_3 = 3CuCl_2 + Fe_2O_3$$
$$3CuO + 2FeCl_2 = CuCl_2 + Cu_2Cl_2 + Fe_2O_3$$
$$CuS + 2FeCl_3 = CuCl_2 + 2FeCl_2 + S$$

NOTE. If the solution is acid the iron remains dissolved in proportion to the amount of acid used.

Copper precipitation

$$CuCl_2 + Fe = Cu + FeCl_2$$
$$Cu_2Cl_2 + Fe = 2Cu + FeCl_2$$
$$2FeCl_3 + Fe = 3FeCl_2$$

Regeneration

$$FeCl_2 + \text{electrolysis} = Fe + Cl_2$$
$$2FeCl_2 + 2Cl = 2FeCl_3$$

Blast-Furnace Gases in Silver-Lead Smelting

Oxygen is present from 0 to 1.5%, and in a well-running furnace not in excess of ½%. With the higher content, namely, toward 1½%, reduction is poor.

In current practice where much sintered ore is used, a good deal of galena remains undecomposed in the sinter. If this is not decomposed in the blast-furnace, some enters the slag as lead sulphate, so that the fume arising from such slag, when it is spilled on the dump, may contain as much as 52% lead.

When the matte goes as low as 12% lead, reduction is good; when it runs up to 22%, the reduction is poor. In the first case the slag may carry no more than 0.5%, in the latter case, as much as 2 to 2½% lead.

All these statements refer to normal tonnage conditions and not when the furnace has been pushed by a plentiful supply of air, exceeding its capacity.

SIXTEEN PLANTS in the United States in 1914 produced 250,635 tons of coal briquettes worth $1,154,678. This was an increase of 37.82 per cent.

Mining in Arizona

By CHARLES F. WILLIS*

The past month has made a record in the annals of Arizona mining. New discoveries galore, record productions at a decreased cost, new plans announced, consolidations, bonding and leasing, and, perhaps, what is best of all, the number of engineers coming to the state to make examinations. Copper is, of course, the most active but this has been closely followed by favorable developments in the new goldfield of Oatman or Gold Road. The demand for properties containing tungsten and molybdenum has been marked and many options on properties of this nature have changed hands, accompanied by increased activity at the mines of tungsten and molybdenum already in operation.

One of the largest transactions consummated in recent years, and from a copper mining standpoint of far reaching effect, is the taking over of the interests of the Gila Sulphide Copper Co. by the American Smelting & Refining Co. This is the well-known Christmas mine, near Hayden, one of the most promising of the low-grade properties in the state. With the necessary improvements to handle a large tonnage, success is assured. It is also reported that the A. S. & R. has purchased the Bush & Baxter mine in the Twin Buttes district. This is a property that will make interesting reading for the get-rich-quick promoter's prospectus. With a total outlay of only $350, to do the assessment work, a few months ago in a neglected district, over $1000 per day is being cleared. The reported sale price is $400,000.

Jerome has turned its attention during the past month to consolidations, the result of which has been that practically the entire district is now in the hands of two companies. Extensive geological work has been recently done in this locality by Walter Harvey Weed, in the employ of the United Verde Copper Co. the result being that the United Verde has taken under its wing all of the properties of the Hull and Cleopatra mining companies, the consideration being stated as about $1,000,000. The United Verde Extension Mining Co., of which James S. Douglas is president, has gathered pretty nearly all of the surrounding claims not included in the United Verde transaction. Deals have been closed on the Hooker and Ewing interests, the Mountain View, the Bouquet, the Parker, the Lippey, the Stifel, and the Johnson groups. By these acquisitions the United Verde Extension owns 30 mines, all of which adjoin the present holdings on the south. The sale of the Harris mine in the Black Canyon district to an Oklahoma corporation is another notable event.

The Globe-Miami district is prominent. Three sections of the Inspiration concentrator, to treat 2250 tons per day, have been started. Two more units will be started during July and probably three more monthly until the entire 18 units are working. This marks the beginning of active production by the Inspiration Consolidated Copper Co. When completed the concentrator will have a capacity of from 14,400 to 15,000 tons daily. Early in the month, the International smelter was blown-in, in the same district; this has been handling the Miami company's concentrate, which has been stored for several months. The International plant will also handle the product of the Inspiration mill. The Old Dominion, although almost drowned in the month of April, has overcome all its difficulties and is back to full capacity. The blowing-in of the third furnace recently has marked its rise to maximum production again.

Two new railroads have been put into operation within the month. A narrow-gauge road, 28 miles long, connects the Magma mine at Superior with the railroad at Florence. This road overcomes the handicap that the Superior district has suffered for many years, and it is now anticipated that there will be increased mining activity there. The town of Mascot was connected with the outside world on June 15. The event was suitably celebrated. The railroad connects the property of the Mascot Copper Co. at the new town of Mascot, in the Dos Cabezos mountains, with the Southern Pacific line at Willcox.

In the southern part of the state much activity is evident. Contracts have been let for the construction of the Gila Bend-Ajo railroad, connecting Gila Bend on the Southern Pacific line with the property of the New Cornelia Mining Co. at Ajo. The contract calls for the completion of the road by January. It is evident that the company is going to lose no time in getting its copper on the market. The road will be about 40 miles long and will have a maximum grade of 0.5%. It is hoped to complete the erection of the reduction plant next year. In the Ajo district, extensive diamond-drill prospecting is being conducted by the E. J. Longyear Co. for the Ajo Consolidated Copper Co. Day and night shifts are being used, and the work is progressing rapidly.

It has been definitely announced that the Sacramento central hoisting-shaft of the Copper Queen Consolidated Mining Co. at Bisbee, will be concreted from the 1700-ft. level to the surface, making it a fire-proof shaft. The work will commence as soon as the material arrives and it is anticipated that it can be done in 60 days. A preliminary test made in this shaft proved that the work could be executed in a satisfactory manner, according to plans already completed, both from the standpoint of expense and workmanship. A novel feature of this work is that it will be the first instance of a shaft being concreted while still in use. Officials of the company express complete confidence that the work will be carried out perfectly, and it will be watched with much interest

*Director Arizona State Bureau of Mines, Tucson, Arizona.

by mining men. This achievement is made possible by the type of form adopted. After the concrete is put in place, all that becomes necessary will be to connect the stringers in the shaft and proceed to the work of hoisting. The placing of the concrete will all be done from skips and cages, no platforms being put in the shaft; it will be started at three places in the shaft, at the 600, 1200 and 1700-ft levels. George Meyers, chief master mechanic, is in charge of the work.

During the past month the Bunker Hill Mining Co., new owners of the old Tombstone Consolidated, will again come into line as producers. The test-mill has been re-constructed and sufficient ore is blocked out to run this mill at the rate of 100 tons daily. During this time the best method of treatment will be determined. It is evident that Tombstone is to be revived. The Bunker Hill Mining Co. is a Phelps-Dodge enterprise, a connection that generally spells success.

All of the large copper mines of Arizona have been pushing their production while copper has been rising but the Calumet & Arizona is passing all records and is now producing almost 6,000,000 lb. per month, although there has been no increase in the number of men employed. The Calumet & Arizona is today a big earner with fine mines producing ores of the direct-smelting class, and its new smelter, the best to be found anywhere. Conditions at the C. & A. allow such flexibility of work as is necessary to meet varying economic conditions, thus permitting high production at a low cost.

Notable among the new discoveries of the past month is that of vanadium in commercial quantities in the Shattuck mine of the Warren district. This mine, which has been familiarly known as "the biggest little mine," has a record for the variety of commercial mineral deposits found within its workings. Vanadium makes a notable addition.

The intense excitement that followed the finding of rich gold ore on Juniper Flats, north of Bisbee, has settled down to the steady development of a few claims. The Truax brothers, who were among the first discoverers of the district, are steadily developing their claims. While it now looks as though it may prove a gold district of some merit, it is not likely to be a bonanza.

Near Kingman, at the Enterprise Mines, rich telluride ore has been reported. Samples assayed at Kingman ran from $4000 to $6000 in gold and high in silver. This property has been recognized for some time as a producer of lead, copper, and zinc. It is evident that the silver and gold values were overlooked.

The development of the Commonwealth Extension at Pearce has recently disclosed 5 to 7 ft. of ore averaging $20 per ton. Machine-drills are shortly to be installed on this property, which aspires to be another Commonwealth, and has a good start in that direction.

Never at any time has the mining situation in the state of Arizona been as promising as at the present time. With the high prices of all the metals, the mines are all working at 100% capacity, and in many cases at an overload. Wages are the highest during the present decade.

Russian Copper Production

The production of copper in the year 1914, according to the report of the Russian syndicate known as the Mied, was not as large as had been anticipated, according to the estimates of the factories included in the syndicate and within its radius of influence. Instead of the expected increase in the production compared with the preceding year by over 400,000 poods (6451 tons), as a matter of fact the quantity of copper smelted did not even reach the level of 1913. It amounted to 1,968,660 poods (31,752 tons) only. Such a reduction, according to the report of the syndicate, must be ascribed in the first place to the influence of the War, which brought about a complete shut-down in the month of October at the Dzansul plant of the Caucasian Copper Co., the failure to start the Kvarty Chan smelter of the Siemens Successors, and the reduced number of workmen at all the remaining plants. Besides these causes of reduced production, the influence of which was seen in the second half of the year, there were others of a sporadic character that acted unfavorably on the production of copper. In the course of the first half of the year, under conditions of peace, all the copper-smelting works, except Kyshtim and Verch-Isset, instead of increasing their production, fell short of that of the preceding year by about 40,000p. (645 tons), and only at the two smelters named was there an increased output: at the former of 34,463 poods (555 tons) and at the latter of 17,605p. (283 tons). Compared with the preceding years the production of 1914 shows as follows:

Total Production of Copper in the Russian Empire

Year.	Poods.	Tons.
1910	1,378,399	22,232
1911	1,564,010	25,225
1912	2,062,731	33,269
1913	2,048,393	33,038
1914	1,968,660	31,752

The production of copper according to districts was as follows:

	1913.		1914.	
District.	Poods.	Tons.	Poods.	Tons.
Uralsk	997,279	16,085	1,026,723	16,560
Caucasus	619,398	9,990	517,452	8,346
Siberia	346,684	5,591	338,088	5,453
Chemical works and refineries	85,032	1,371	86,397	1,393
Total	2,048,393	33,037	1,968,660	31,752

The consumption of copper in Russia for 1914 amounted to 2,072,318p. (33,424 tons), or 10,614p. (171 tons) more than in 1913 and 192,659p. (3107 tons) more than in 1912. According to estimates, the production of copper in 1915 is expected to be 2,165,000p. (34,919 tons), or 196,340p. (3166 tons) more than in 1914.

In view of the exceptional circumstances* under which the Caucasian Copper Co.'s works are placed, no copper is expected to be produced there this year. Last year this company produced 192,538p. (3105 tons).

*The mines and smelters are in a region now the scene of military operations between Russia and Turkey.

Concentrates

Readers of the Mining and Scientific Press are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

Flow of liquids is faster from a square orifice than from a round one.

Scrap metal worth over $50,000,000 is recovered in the United States each year.

Ancient river-channels in Sierra county, California, have averaged $150 to $500 in gold yield per linear foot.

Efficiency of belting depends primarily on its strength, speed, and the arc of contact with its pulleys.

Design or lay-out of underground tramming systems, especially switches and crossings, is of considerable importance in a mine of large output.

Ball-bearings are considered a success in electric motors. Mining locomotives, which get fairly rough usage, are fitted with them, resulting in decreased repair bills.

The advantages of using dynamite that will not freeze until after water freezes, is recognized by practically all large users of explosives whose operations are carried on in freezing temperatures.

Blast-furnace slag was considered a nuisance in reducing iron ores. Now it is a valuable residue, as it is used in road construction, ballasting, railways, concrete, fire-proof floors, roofing gravel, and in the manufacture of cement.

Leather belts are affected by changes in the weather. A damp atmosphere lengthens these belts, decreasing their tension on pulleys. Balata belts get very slack in dry weather, and tight when wet. Rubber belts are hardly affected.

Extractions of metal based on differences of assay-results in experimental work should be definitely stated as assay-extractions, and should be clearly distinguished from possible or probable recoveries. The actual extraction sometimes exceeds the assay-result, but when it exceeds 100% it shows that the sampling is not accurate.

Leaky pipe-lines may be repaired cheaply by oxy-acetylene welding. At Ophir, San Miguel county, Colorado, pipes at the Carribeau mine required over 100 patches. In two days these were repaired at a cost of one-third of what new pipe would cost, not counting a shut-down to put in new pipe.

Pennsylvania oil is practically free from sulphur and asphalt, is rich in paraffin wax, and yields a high percentage of gasoline and illuminating oil. For many years it has been first in demand by the refiners, and though modern refining methods have succeeded in remedying to a notable degree the deficiencies of crude petroleum from other parts of the United States, Pennsylvania grade still retains its rightful prestige and forms the criterion by which the merits of other crudes are judged.

The Government employs geological and mineral experts to make examinations of mining claims within the National Forests; but, unless the claims are actively interfering with the administration of the Forests, no examinations are undertaken until application for patent is made. The proportion of mining claims examined prior to application for patent is very small, probably less than 1% of the total number located. There are thousands of mineral locations within the National Forests of which no examination has been made by the Forest Service, and in all probability never will be except in cases where application for patent is made.

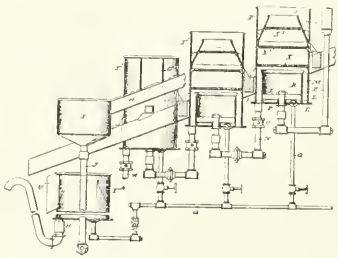
Terne plate is made by passing thoroughly cleaned steel plates through molten terne mixture. This terne mixture is an alloy of pure tin and pure lead in varying proportions, the most common mixture being 27% tin and 73% lead. When plates emerge from the bath of molten metal they are thoroughly covered with a fairly uniform coating of this alloy. Since terne mixture itself is practically incorrodible, long service may be expected from a roof formed of this material. Terne plates are furnished commonly in sheets 20 in. by 28 in., 112 sheets to the box, but as in the case with galvanized and black sheets it is also furnished in the form of roll roofing where the sheets are soldered on the ends and ready to roll out on the roof and fasten at the sides in one of the well-known methods of flat-seam or standing-seam construction.

Nickel may be qualitatively detected in ores by powdering a small sample and dissolving it in aqua regia. The solution should contain 10 to 15 c.c. of double normal acid to every 100 c.c. of solution. H_2S is then passed into it until it is saturated, dilute with an equal volume of water and pass in H_2S until it is again saturated. Filter off the precipitate, the nickel is in the filtrate. Boil out the H_2S, add ammonia to alkaline reaction, and then add colorless $(NH_4)_2S$ until no further precipitate is produced. The nickel is in the precipitate. This should be washed four times with water containing $(NH_4)_2S$, three times with pure water and then treated, with constant stirring, with cold double-normal hydrochloric acid until no more H_2S is given off. Any precipitate that remains undissolved may be the sulphide of nickel, cobalt, or both. Wash it well, and dissolve in aqua regia, evaporate the solution to dryness. Dissolve in a little water and add KCN solution drop by drop until the precipitate first formed re-dissolves completely; 2 or 3 c.c. of caustic soda solution is then added and chlorine conducted into the cold solution. If nickel is present a black precipitate of $Ni(OH)_3$ is formed within a few minutes.

Recent Patents

1,141,377.—Ore-Concentrating Apparatus. John M. Callow, Salt Lake City, Utah, assignor to Metals Recovery Co. Filed October 6, 1913. Serial No. 793,695.

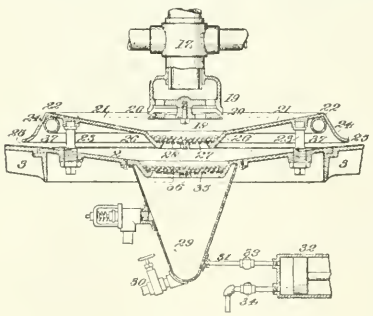
1. In apparatus of the character described, the combination of a tank or receptacle adapted to receive ore pulp and a substance having the property of frothing in the presence of a gaseous medium and agitation, a casing within the lower portion of the tank and separated therefrom to form a surrounding space or chamber, a body of porous material within said inner casing and supported above the bottom thereof so as to



form a chamber between said porous body and the bottom of the tank, a feed pipe terminating in the lower portion of the tank above the porous body and adapted to deliver the pulp into the casing above said body, a pipe leading into the chamber below said porous body and adapted to admit a gaseous medium under pressure thereinto, said porous body subdividing the gaseous medium and distributing the same irregularly substantially throughout the entire surface of the pulp, and a discharge means connecting with the space or chamber between the inner casing and the tank and adapted to deliver therefrom the heavier material which has settled into said space.

1,141,419.—Combined Batea, Jig, and Pan Motion Concentrator. Karl Senn, Alameda, California. Filed June 18, 1914. Serial No. 845,841.

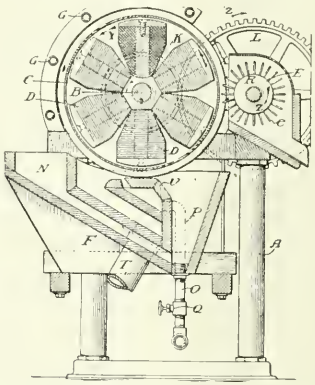
1. The combination in a concentrator, of a concave pan with a central discharge, means for feeding pulp at the centre of the pan, a screen in the pan discharge and supporting a mobile



mass, the particles of which are too large to pass through the screen, means for gyrating the pan to agitate said mass and the ore solids concentrated, the concentrate gravitating toward and through the screen and the gangue being washed outwardly by the wave action and water flow, means for hydraulically jigging the concentrate and the mobile mass at the screen, and a preliminary separator superposed above the pan discharge and into which the feeding means discharges pulp, the rim of the separator being adjustable relative to the surface of the pan to form an annular mouth, through which a counter-current, derived from the jigging means, runs outward.

1,141,833.—Magnetic Ore-Separator. Sven Ragnar Salwén, Grangesberg, Sweden, assignor to American Grondal Co., New York. Filed October 9, 1914. Serial No. 865,924.

1. In a magnetic separator, a plurality of magnets of alternating polarity mounted on a suitable axis, a rotary magnetic drum arranged around said magnets and in close proximity to

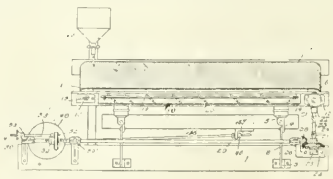


their poles, and means for rotating the magnets and drum simultaneously in opposite directions.

2. In a magnetic separator, a plurality of magnets of alternating polarity mounted on a suitable axis, a rotary magnetic drum arranged around said magnets and in close proximity to their poles, and means for rotating the magnets and drum simultaneously in opposite directions in combination with means for washing the ore while it is tumbling over the face of the drum.

1,141,852.—Process of and Apparatus for Sizing of Classifying Comminuted Materials. Henry M. Sutton, Walter L. Steele, and Edwin G. Steele, Dallas, Texas. Filed July 21, 1913. Serial No. 780,360.

1. The process of sizing a mass of comminuted material, consisting in subjecting a mass of material containing particles of



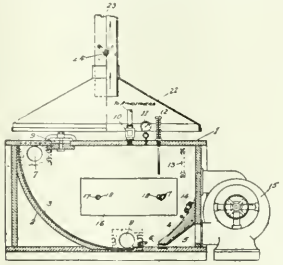
different sizes in dry condition, to a continuous movement in one direction upon a moving support, causing the particles to gravitationally deviate from the line of normal movement, retarding said gravitational deviation and so proportioning the forces, that the deviation shall be proportional to the size of the respective particles, and separately collecting the thus sized particles.

2. The process of sizing a mass of comminuted material, con-

sisting in subjecting a mass of material containing particles of different sizes in dry condition, to a continuous movement in one direction upon a continuously moving support, causing the particles to gravitationally deviate from the line of normal movement of the material, retarding said gravitational deviation to cause the particles to travel contiguously and so proportioning the forces, that the deviation shall be proportional to the size of the respective particles, and separately collecting the thus sized particles.

1,142,462.—Ore-Disintegrator. Leon St. D. Roylance, San Francisco, California. Filed December 27, 1912. Serial No. 738,830.

1. In an ore-disintegrator, a tank for holding the solution containing the ore, an abrading surface within said tank, elec-

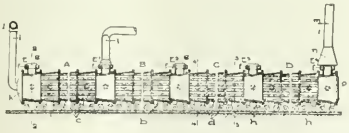


trodes positioned within said tank and means for causing the contents of said tank to circulate to impinge upon said abrading surface and pass between said electrodes.

2. In an ore-disintegrator, a tank for holding the solution containing the ore, an abrading surface within said tank, electrodes positioned within said tank, a compartment provided with an elongated opening to said tank positioned opposite said abrading surface, and means for drawing solution from the tank and returning the same to the tank by discharging into said compartment.

1,142,324.—Treatment of Subdivided Ores for Agglomerating or Reducing them and Apparatus Therefor. Gustaf Gröndal, Djursholm, and Herman Nilsson, Nyhammar, Sweden. Filed May 23, 1914. Serial No. 840,549.

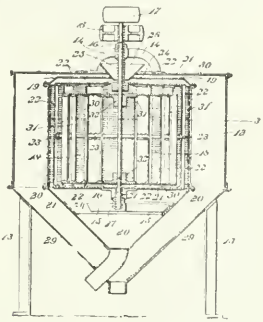
1. A method of treating subdivided or pulverulent ore consisting in packing the ore, in a moistened state into an iron receptacle open at both ends, providing longitudinal channels in the ore, arranging a number of such filled receptacles in



series adding thereto a suitable fire-place, passing the combustion products through the said channels until the ore in the receptacle lying next to the fire-place is brought to the desired state, afterward removing this receptacle containing the ore and placing it on the other side of the fire-place to be traversed by the air for combustion moving the series of remaining receptacles toward the fire-place and placing another receptacle filled with fresh ore at the other end of the series, and so on, substantially as described.

1,141,988.—Screen or Separator. Thomas Joseph Sturtevant, Wellesley, Mass., assignor to Sturtevant Mill Co. Filed March 1, 1913. Serial No. 751,560.

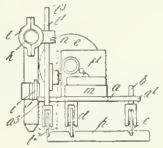
1. In a separator, the combination with a suitable casing, of a vertically disposed stationary screen within the said casing, a vertically disposed rotating fan arranged adjacent to said screen and provided with alternating reversely inclined blades all disposed in one circular plane and serving to produce alternating reversing or pulsating air currents, and means for



supplying to the upper part of the separating means the material to be screened.

1,141,560.—Apparatus for Severing Metals by Fusion. Charles Tibbit Lack, Impington, England, assignor of one-half to Chivers & Sons, Limited, Histon, England. Filed November 25, 1914. Serial No. 874,053.

1. In apparatus for severing metals by fusion, the combination with a blow-pipe, of a carriage, adjustable wheels on said

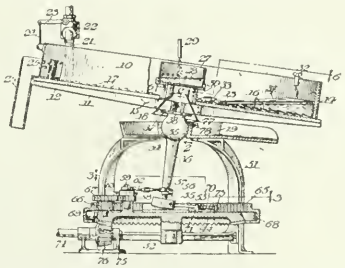


carriage for adjusting the angle of cut and a motor geared to one of the wheels of the carriage to propel the same during the severing operation.

2. In apparatus for severing metals by fusion, the combination with a blow-pipe, of a carriage, adjustable wheels on said carriage for adjusting the angle of cut, a motor geared to one of the wheels of the carriage to propel the same during the severing operation, and an adjustable support carried by the blow pipe for controlling the path of movement of the carriage.

1,141,972.—Pan-Motion Concentrator. Charles H. Muhleman, Western Springs, Ill., assignor of fifty-five one-hundredths to Frank Low, St. Louis, Mo. Filed June 4, 1914. Serial No. 842,862.

1. In a concentrator, in combination, a pan and a supporting column therefor, means for tilting the column, means for tilt-



ing the pan independently of the column and means for revolving the column about a vertical axis without rotation of the column.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

PLATTEVILLE, WISCONSIN

Worries of Zinc-Ore Producers.—New Separating-Plants.—Ore Prices.—Calamine.—District Outputs and Buyers.

In many ways June was an interesting month in the zinc-ore mining districts.

Probably in no other region in this country is there so wide a disparity in metal content as found here. Production includes material by wet concentration containing from 20% to 60% zinc. As long as smelter representatives offered a market for the medium and lower grades, operators were content to make delivery with a small profit. These same low-grade producers thought that the rapidly advancing offers for both metal and ore would enable them for once at least to get a fair return on their labor and investment. Instead, as the demand for metal became radically abnormal, so also became the demand for high-grade ore only, which could be converted into metal quickly. Low-grade producers found themselves utterly ignored. Production was splendidly maintained regardless of the absence of demand, until at the close of the month there was 10,000 tons of surplus ore at all points containing under 50% zinc. Machines were needed to make better products. The Mathey revolving cylinder and the Cleveland-Knowles and Dings' separators have been in use in this field for many years. The introduction of electrostatic separation found two types of machine adaptable for this method of reduction to high-grade product only, the Blake-Morscher and the Huff (Boston) type. The latter has gained more in favor until today it is greatly used, yielding as high as a 62% zinc product.

The abrupt demand for finished product found the few separating-plants in the field utterly unable to meet the demands made on them, and mining concerns decided quickly, with the following results: A new 1000-ton separating-plant of the Skinner type is being constructed in the New Diggings district; a new custom-plant is being built in the Mifflin district to accommodate the Peacock Mining Co. and others in the immediate vicinity; in the Platteville district the independent separating-plant of the Homestead Mining Co. has been converted to public patronage, and all low-grade producers are turning their output into the plant for reduction; in the Shullsburg district the Fields Mining & Milling Co. is rushing to completion a new separating-plant to handle the ore from two producers capable of supplying 800 tons of raw ore per week; the National Separating Works has increased the capacity of its plant at Cuba; and the same was done at the Linden and Mineral Point establishments. While production of raw ore is to be considerably increased by the starting of a score of new producers on thoroughly proved properties, deliveries will scarcely show much increase in tonnage. The gain will all be in the value made. In addition, a stronger element of competition will be injected into the field on high-grade open-market offerings exclusively, as is already witnessed in the introduction during the month of new buying interests, notably the Robert Lanyon Zinc Co., Picher Lead Co., Granby Mining & Smelting Co., and the Edgar Zinc Co.

Zinc ore at the beginning of the month was bid in on a basis of $68 per ton for 60% metal content. Operators alleged that smelters were giving them a bad deal. Whether this was true or not, there may have been something in it as the Picher Lead Co.'s buyer immediately raised the price of 60% ore to $90 per ton. After several weeks $130 per ton had been reached. The best information during the month came from the Fields Mining & Milling Co., which, under contract based on the ruling quotations on spelter enabled it to secure $156.11 per ton for 42% product. Four cars of ore realized over $20,000. Fortunately for the smelters, many of whom contracted metal long periods in advance at 7 and 8c. per pound, not many contract arrangements for ore deliveries existed, and contracts expiring have not been renewed. Smelters have been hard hit on the lower-priced metal deliveries, by being compelled to pay high prices for ore. The close of the month found both ore and metal receding, but still remaining abnormally high. Zinc-ore bids ranged at the close of business June 30 from $90 to $115 per ton 60% basis. Buyers also showed less inclination to submit offerings, some even admitting instructions demanded restriction in buying.

Lead ore started the month at $52 per ton for 80% metal content. Here also sensational developments featured business, prices advancing rapidly to $60 per ton. New buyers again were responsible for improved offerings, and bidding revealed inside deals at $70 per ton. This figure was not long maintained, and the end of the month saw lead ore established firmly on a base of $60 per ton. Considerable ore of this class held close, came to the surface, and deliveries were slightly improved, but producers showed little disposition to unload. The reserve in the field at the end of June was over 2500 tons.

Pyrite business was fairly good, when on June 15 the burning of the Wilkinson mine equipment, removed the chief producer. The plant will be re-built without delay, production will be maintained. Separating-plants securing pyrite as by-product, unloaded freely during the month at an average of $3.75 per ton f.o.b.

Carbonate zinc ore producers held for years under the control of the New Jersey Zinc Co., witnessed the most remarkable advances of any branch of the industry, the calamine base of the Missouri field applying to this commodity. At no time has ore of this class changed hands at over $20 per ton, but near the end of the month offerings were strong at $80 per ton, 40% zinc. The Wisconsin ore is converted into zinc oxide, which is mostly used in the manufacture of paint. The Picher Lead Co. again violated all injunctions of the 'fraternity' by breaking into the northern districts for carbonate ore to be used in the manufacture of spelter. The ore was delivered to the smelter at Collinsville, Illinois; under lease to the Picher Lead Co. Thousands of tons of mill-feed are being piled on the dumps, and the season's clean-up was well on all the month.

Shipments in June were as follows:

Districts	Zinc Pounds	Lead Pounds	Pyrite Pounds
Benton	9,898,000	64,900	1,465,300
Galena	4,976,000	162,000	.....
Hazel Green	4,178,000	60,000	.....
Cuba City	3,054,000	.....	1,469,440
Platteville	2,792,000	.....	.....
Livingston	2,534,000	.....	.....
Linden	1,230,000	.....	.....
Dodgeville	632,000	.....	.....
Shullsburg	616,000	.....	.....
Highland	576,000	.....	.....
Mifflin	364,000	.....	.....
Mineral Point	104,000	.....	.....
Total	30,954,000	286,900	2,934,740

The sales were divided among the following buyers: Mineral Point Zinc Co., 5843 tons; National Zinc Works, 2212; American Zinc Co., 1875; Matthieson & Hegeler Zinc Co., 1071; Empire Roasters, 964; Illinois Zinc Co., 778; Grasselli Chemical Co., 682; Campbell Roasters at Cuba, 530; Linden Zinc Co., 448; Picher Lead Co., 376; American Metals Co., 282; Granby Smelting Co., 98; Edgar Zinc Co., 40; Lanyon Zinc Co., 339 tons.

Newly-developed mines were brought to the producing stage; others were closed on account of the market; and to prevent a strike among miners as in Missouri wages were raised 25c. per day.

During the week of June 20, Attorney-General Barker, of Missouri, filed information in the state Supreme Court against 28 companies alleged to be interested in the purchase of zinc ore in the Missouri districts stating that he had reason to believe they were in an unlawful combination to control prices. All of the companies represented in the Wisconsin field were cited. The court is asked to appoint a commissioner to take testimony, with the ultimate view of filing proceedings against any or all of the companies the testimony may show guilty of the practices charged.

CRIPPLE CREEK, COLORADO

Gold Output in June.—Golden Cycle, Portland, Blue Bird.

The estimated production from the Cripple Creek district during June, as reported by the mills and smelters, is as follows:

Plant	Tons	Average value	Total
Smelters	4,700	$55.00	$258,500
Golden Cycle Mill	36,000	20.00	720,000
Portland, Colorado Springs	12,000	19.50	234,000
Portland, Cripple Creek	18,250	3.14	57,305
Stratton's Independence	8,000	3.20	25,600
Gaylord	1,800	2.50	4,500
Wild Horse	690	3.50	2,380
Total	81,440	$16.00	$1,302,285

During the month five of the local mills were shut down most of the time for various reasons. The Kavanaugh, Neville, Ajax, Isabella, and Jerry Johnson mills did practically nothing during the entire month.

It is expected that the Golden Cycle Mining Co. will pay its regular monthly dividend of 2c. per share on July 10. The distribution will be $30,000.

At a recent meeting of the directors of the Portland company it was decided to increase the regular dividend for the current quarter of the year from 2 to 3c. per share. This dividend will be paid on July 20 to stockholders of record on July 12, and will amount to about $90,000. This will bring the total dividends paid by the Portland company to a little more than $10,000,000.

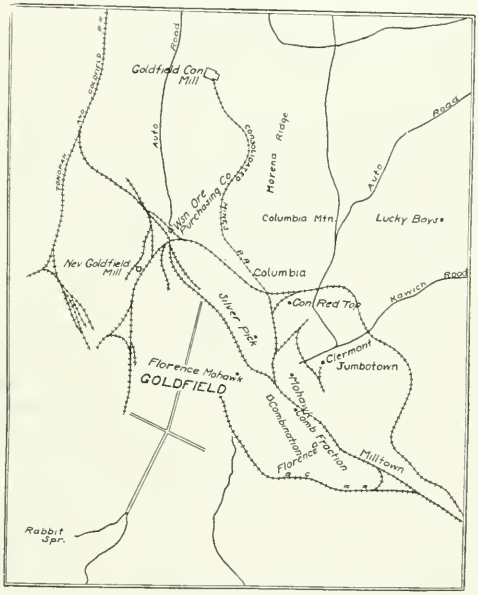
[At the Palace of Mines and Metallurgy at the Exposition at San Francisco, a model of the Portland company's sampling-plant is shown. It is driven by a ¼-hp. Westinghouse motor. The Short Line train brings ore to a large bin. The ore-flow is then as follows: jaw-crusher, elevator, rolls, trommel, coarse from trommel returned to rolls by No. 1 elevator, high elevator feeding Vezin sampler, first cut through rolls, three cuts in all, excess ore then taken by belt-conveyor to railroad cars.—Editor.]

The past week has been a broken one, and generally quiet. All of the mines and mills shut down for two days over the Fourth and fifth. Numerous reports may be heard about important developments being made, however, if one bears in mind that "many are called but few are chosen" he will not believe all reports about wonderful discoveries. Nothing new has developed concerning the new Blue Bird mill. It is generally thought, however, that as soon as the preliminary plans are completed, the option on the estate will be taken up and construction on the mill started. The dry clear weather which the district has enjoyed for the past few weeks has greatly favored the working over of old dumps. Considerable revenue is being earned from this source.

GOLDFIELD, NEVADA

District Tonnage.—Jumbo Extension Yield, Developments, and Management.—Merger and Atlanta Companies.

Companies and lessees of this district are sending over 300 tons of smelting ore daily to the sampler of the Western Ore Purchasing Co. This comes principally from the Jumbo Extension, Atlanta, and Florence Mines, and from leases on the Red Top and Jumbo claims of the Goldfield Consolidated Mines Co. The Consolidated mill is treating 1070 tons per day. The equipment installed for the treatment of tailing, to supplement the production from the mines, has not been started yet, as there has been no lack of ore. Complete tests



GOLDFIELD DISTRICT, NEVADA.

are to be made with oil-flotation and other processes to devise a method by which the low-grade, refractory ores of the district can be treated profitably. It is reported that these tests will be made at the Consolidated mill.

J. K. Turner, in charge of the Jumbo Extension mine, estimates that company's June production at 2358 tons shipped to smelter, with a gross value, as indicated by control assays, of $93,000; freight, sampling and treatment costs $24,000; operating expenses $15,000; and net realization $54,000. This product was shipped to the sampler in 50 steel ore-cars. From January to June production was nominal and insufficient to pay costs, as the company was working under an injunction, issued by the Federal court at Seattle upon application by the minority faction of the Merger Mines Co. directors, and all receipts from ore marketed during that period were impounded in the bank. The company has since been freed of all litigation. Production will continue for the present at about the same rate as in June, owing to the limited capacity of the main Polverde shaft; but with the completion of the Velvet

shaft to the 1017-ft. level the output can be easily more than doubled. The best ore is exposed in the wide fissure that extends within the shale, but a larger tonnage, of almost equally good grade, is now exposed at the shale-latite contact, the latter channel lying above the former, both dipping south at about 30°. A drift lately started from the most southerly raise, No. 526-A, at a height of over 60 ft. above the 1017-ft. level, has exposed 6 ft. of $65 ore, while another raise and drift, at almost the same height show the same character of ore on the contact fully 300 ft. to the west. This is within approximately 250 ft. of the south end-line of the Jumbo Extension property, and less than 500 ft. from where the Merger Mines Co. is seeking the continuation of this orebody on the shale-contact, at a depth of 1175 ft. Six new faces in the Jumbo Extension mine, all in the newer workings at the south and all on the shale-contact, are showing high-grade ore, varying from $50 to $250 per ton. Nearly all recent production has resulted from development work, but stoping will be carried on east of the raises from the 1017-ft. level, in order to make room for filling with waste. Work is now being directed to the western part of the mine, where little development has been done, as the limits of the orebody have not been defined in this direction. Cross-cuts that were driven far to the southwest, in the shale, on the 921 and 1017-ft. levels, and which were long regarded as useless work, will now serve to facilitate the work in this part of the mine. The annual stockholders' meeting of the Jumbo Extension company will be held at Phoenix, Arizona, on July 19. The new board of directors will probably be composed of Charles S. Sprague, J. K. Turner, Ben Gill, A. I. D'Arcy, and Willard P. Ward of Colorado Springs. Mr. Sprague will be chosen president, Mr. Turner general manager, and Mr. Gill secretary and treasurer. Mr. D'Arcy will represent the Booth company's stock interest, recently acquired in settlement of that company's apex claims. Mr. Sprague already has more than enough proxies to control the meeting and all the principal stockholders will give him their support.

In Merger Mines territory, work is confined to the east drift along the shale-contact, at a depth of 1175 ft., and short raises from this drift, at intervals of 40 ft., to prospect the latite hanging wall, as in the Jumbo Extension mine the best ore of the contact area is found on this side of the silicious mass that lies between the latite and shale. The Jumbo Extension orebody appears to extend directly toward the Merger, but the latter may be compelled to drive from 100 to 200 ft. farther before finding this ore. The great fissure, in which high-grade ore is found in large quantity in the Jumbo Extension, also appears to dip into Merger ground and much interest will attach to the exploration of this fissure south of the Merger boundary and to the conditions that will be revealed at the point where this fissure reaches the basic granite, below the shale.

The future of the Atlanta mine must depend, in large measure, upon the discovery of a process by which the low-grade, base ore of this property can be treated. The main cross-cut on the 1750-ft. level was advanced through the vein for 107 ft., but not directly across the lode, which is approximately 80 ft. wide here. The manager, A. I. D'Arcy has reported that nearly all the material passed through by this cross-cut can be treated profitably with a suitable reduction plant on the ground. Smelting ore assaying $20 per ton is shipped at the rate of 50 tons daily. There is a considerable quantity of this ore available.

A west cross-cut at 500 ft. in the Silver Pick recently revealed the downward extension of the old Phelan lease vein. So far, it is 12 ft. wide. The assays, although low, are encouraging. A large flow of water was also encountered.

Several Goldfield men went by auto on July 12 to Silver Crown, the old Stimler centre, 50 miles west of Goldfield. They will inspect the mines and return next week.

LONDON

Spelter and Broken Hill.—Zinc Corporation.

The attitude assumed by the British government with regard to zinc is galling to the mines, and also to the makers of munitions in this country. The sanctity of international law is apparently of greater moment to the Government than the requirements of the Allied armies on the battlefields. Zinc concentrate shipped from Australia to Germany just before the outbreak of war is held as prize of war in English ports. English companies are not allowed to terminate their long-time contracts with German buyers, but must hold their production and re-commence delivery at the end of the war. In Australia efforts are being made to pass a law through the Federal parliament that will permit the mines to re-arrange their contracts. Any such easing of the situation would not help the Zinc Corporation or the Sulphide Corporation, which are both companies operating at Broken Hill, but registered under English laws. In some quarters the position does not create irritation, for it is held that no alternative method of disposing of zinc concentrate can be devised. The sale to American smelters is not considered as highly remunerative, even at the present level of prices, and the American smelters are reported not to be enthusiastic about the complex Australian product. As for starting zinc-smelting works in England, it is argued that two years would be occupied in building a plant, that suitable labor could not be procured, and that the money required for capital outlay is not forthcoming. Thus a general attitude of *non possumus* or 'it-can't-be-done' is prevalent. In the meantime the Broken Hill companies are doing their best with the production of lead, and the Associated Smelters Co. has been formed to operate the Proprietary's smelter at Port Pirie, under the joint ownership of the Proprietary, North, and South companies. Since its formation, the Zinc Corporation has taken a share to the extent of £100,000, and the money to purchase this share is to be raised by loans against profits.

The position of the Zinc Corporation deserves mention. On the outbreak of war, the finances were greatly inconvenienced by the moratorium, which prevented the directors calling in the funds that had been lent on short notice, so that the payment of the preference dividend had to be postponed, and also the payment of the purchase price of the Barrier South control. But this stringency has long passed away. The corporation, however, is feeling the inconvenience of not being able to collect a sum of over £45,000 from Aron Hirsch und Sohn, of Halberstadt, Germany, for zinc concentrate delivered, and an action has been entered in the Australian courts for the recovery of this amount. The necessity for such an action is intelligible only to those who are harassed by legal absurdities, national and international. It is presumably devised as a means for the eventual annulment of the Hirsch contract. In reading the report for the results during 1914 it is necessary to remember that the Corporation was formed 10 years ago to treat by flotation methods tailing-heaps containing large amounts of zinc, that had been accumulated by various mines at Broken Hill, and that in 1911, the position was strengthened by the absorption of the mine and plant of the South Blocks company, which was formed in the same year as the Zinc Corporation by the same group for the purpose of working the lead-zinc mine at the southern end of the Broken Hill district. The Barrier South company, of which control has recently been purchased, owns the mine to the south of the South Blocks, in earlier days called the South Extended. The work done by the Zinc Corporation now consists of mining and milling the South Blocks ore and treating the old zinc-tailing dumps. An abstract of the results in 1914 appears on page 91 of this issue. The revenue from concentrate, etc., was £448,992. Total charges were £330,042. Preference shares were paid 3s.6d. (84c.), and ordinary, 1s.6d. per share. Concentrate on hand is valued at £27,222. Investments are worth £226,947.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

In Alaska stibnite is one of the most widely distributed of ores, occurring as an accessory in many other ore deposits. Antimony bearing veins have been found on Seward peninsula, in the Nome river basin, on upper Fish river, and in the Kantishna district. Stibnite was frequently found in the concentrate from alluvial mining in the Fairbanks district and was later found in veins in many places in the district. A stibnite vein occurs at Port Wells, Prince William sound.

Fairbanks

All the creeks in the Fairbanks district are the scenes of unusual activity. Everybody is satisfied with the outlook. Up to the beginning of June the gold output was reported to be $300,000 greater than for the season up to that date of 1914. This results from earlier sluicing, four weeks in places.

At Tolovana a ditch is to be dug from Mike Hess creek to Livengood creek. This work will take most of the summer to complete. Ten sluice-heads of water will be available in the summer.

Juneau

The repaired shaft for the Central hoist at Treadwell was expected to be in place by July 10.

The Alaska-Juneau company will double-track 5500 ft. of its tunnel from the mill to the mine, according to P. R. Bradley. Grading for the mill is to be done this summer, but the plant will not be built until late in 1916. The Marcy ball-mill is to be experimented with. There are 300 men employed at present, in charge of J. Richards.

The Gastineau mill is treating 4000 tons of ore per day. Within a month this quantity will be increased to 6000 tons.

In the hills above the timber line the Alaska Gold-Belt company has machine-drills driving an adit, and by July 20 it expects to enter the ore-zone. This adit should cut ore at a depth of over 3000 ft. A lower adit has been started from the beach. A large tonnage of ore is calculated should be opened by this work.

Interesting contests were held at Treadwell on July 5. Three teams of six men each entered the first-aid display. The Mexican team won the prize of $150 with a rating of 97%; the Bullion followed with 93%; and the Treadwell with 92% winning $60 and $30 respectively.

In the fire-hose contest, stringing five lengths of hose from a hydrant 230 ft. distant, making connections and getting water, was won by the Bullion team in 19⅗ seconds. No other team succeeded in getting water under 28 seconds, the time limit first trial. In the second run the Cyanide team made it in 21 seconds, taking second money. The prizes were $250 for first and $100 for second.

ARIZONA

Mohave County

In the first half of 1915 the Oatman district's gold output was approximately $1,000,000 from 85,000 tons of ore, reduced by 60 stamps, and then cyanided. The Tom Reed and Gold Road mines were responsible for this yield. The June production was $165,000 from 14,000 tons. From January to July the Tom Reed returned $520,000 from 26,000 tons. Dividends in that period amounted to $272,886, or 30c. per share.

Seven claims, adjoining the United Western at Oatman, have been purchased by Globe and Miami men. A company is to be organized under the title of Clarissa Gold Mining Co. It will await further development in the United Western before starting.

ARKANSAS

Sevier County

Near Gillham, Arkansas, oxides and sulphide of antimony occur in quartz veins following the bedding planes of the shales and sandstones in which they occur. The orebodies occur in lenticular masses. They were first worked in 1873, and a desultory production was maintained from about ten mines for thirty years thereafter.

CALIFORNIA

Calaveras County

The old Thorpe mine's new shaft is down 67 ft. A 5-drill motor-driven compressor is being installed. A. H. Summerville is superintendent.

Inyo County

At the south end of Death Valley is a new district known as Silver Lake. Railroad is not far away. While water is scarce, it may be obtained from wells of moderate depth. There is little vegetation, and plenty of shifting sand. Temperatures rise to 130°F. in the shade. In the property of P. H. Lietzow and T. Koerner, high-grade gold ore has been opened, with some silver and copper. Country rocks are diorite and granite.

Kern County

A good deal of interest is being taken in the antimony deposits of this county. The San Emidio district contains several promising veins. The Kern County Land Co. owns land there. Erskine Creek deposits, 50 miles from Caliente, are attracting attention. Rich ore is said to have been found on Greenhorn mountain.

Nevada County

It is probable that the Kenosha mine near Grass Valley will be re-opened soon. The shaft is down 450 ft. on the incline. Financial troubles were the cause of the shut-down.——The Goodwin and Nicholls drift-gravel claims of the You Bet company have been leased to a syndicate of Chinamen, who will employ 75 men. San Francisco Chinamen are said to be largely interested.

Placer County

Development at the Herman mine near Westville has been very encouraging of late, notably on the Cavins vein. Trenching uncovered this orebody for 800 ft., where it was from 4 to 13 ft. wide. Four feet on the foot-wall assays from $2 to $12 per ton. The drainage adit is expected to cut the vein. A 30-stamp mill and other machinery is ready for work. S. H. Brockunier is in charge.

Plumas County

Several claims in the Soda Creek district are developing into profitable mines. At the Compton and McBeth Monitor mine a 6-ft. vein has been opened. A Straub 10-stamp mill is reported to recover $10 per ton. More stamps will be erected.

Shasta County

The old Greenhorn mine is shipping eight tons of very rich copper ore per day to Keswick. Some of it contains 60% metal. Haulage costs $6 per ton. High-grade streaks run through the main shoot, which is of peculiar formation.

Sierra County

The Downieville-Alleghany-Forest district is very active,

both prospecting and mining. Fifty men are employed at the Gold Bluff-Oxford mine in charge of G. Snyder. The 20-stamp mill is working. The Gold Point is being placed in condition for a larger output. Ten stamps are ready. Twenty stamps are crushing at the Monarch-Cleveland mines. D. McGonigal is manager. Shaft-sinking is progressing well at the Tightner. About 100 men are employed.

In three weeks' time the new 15-stamp mill at the Plumbago mine was erected. R. L. Hathaway was the contractor.——At the South Fork mine it is thought that the Tightner vein has been cut.

Siskiyou County

At the old Mt. Vernon mine on Cherry creek, J. S. Dobyns has opened a shoot for 300 ft., assaying from $5 to $18 per ton. A 500-ft. cross-cut adit is to driven. Five stamps are at work.——It is reported that T. George and sons, and R. Brown have sold their placer mine for about $20,000. It is situated on the east fork of the Salmon river.

Tuolumne County

(Special Correspondence)—At the Santa Ysabel mine, two miles south of Jamestown, the main shaft is being steadily unwatered. Work has been started at 400 ft. to develop the Mascot vein. Ore in this vein above 250 ft. will keep five stamps busy. Lessees in the Knox and Boyle mine are breaking a full face of ore in the south drift. The entire stope is in ore on the 700-ft. level, which is being broken with two machines working two shifts. Ten stamps are crushing this ore. It is the intention to keep the mill in operation continuously. The west vein will be developed from the 600-ft. level west from the main shaft, where there is over 50,000 tons of good grade ore available. Upon the development of this body the capacity of the mill should be maintained with 40 stamps in operation.

Jamestown, June 28.

A drilling contest was held at Sonora on July 4. It resulted as follows: Peyton and Dynon, 36⅝ in.; Pedro and Marcus, 36 7/16; Lumsden Bros., 36 1/16; Jacovovich and Vucasovich, 33; and Page and Bartlett, 24¾ inches.

COLORADO

The output of Colorado mines during 1914, according to figures compiled by Charles W. Henderson, of the U. S. Geological Survey, was $19,883,105 in gold, 8,796,065 oz. silver, 74,211,898 lb. lead, 6,639,173 lb. copper, and 96,774,954 lb. zinc (in terms of spelter and zinc in zinc oxide), with a total value of $33,460,126, compared with $18,146,916 gold, 9,325,255 oz. silver, 87,897,773 lb. lead, 7,227,826 lb. copper, and 119,346,429 lb. zinc, with a total value of $35,450,585 in 1913. This shows an increase of $1,736,189 gold, and decreases of 529,190 oz. silver, 13,685,875 lb. lead, 588,653 lb. copper, and 22,571,465 lb. zinc. In addition to the decrease in quantities of silver and the base metals, the falling off in average value for these metals caused a decrease in value of $768,230 silver, $973,238 lead, and $1,747,877 zinc.

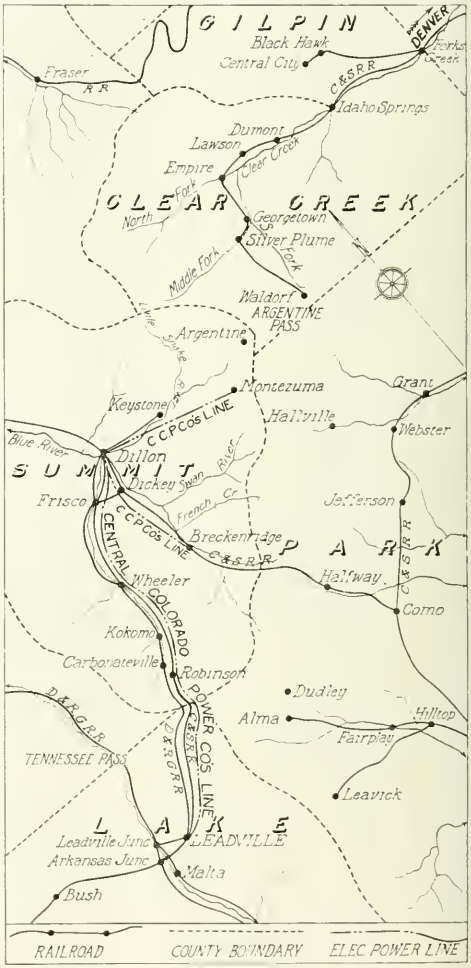
There was a total of 2,677,526 tons of ore treated. The largest tonnages were in the following counties: Teller, 939,423; Lake, 547,463; San Miguel, 495,942; Pitkin, 118,000; San Juan, 117,988; Ouray, 105,560; and Clear Creek, 101,366 tons. Cripple Creek produced 60% of the total gold yield, contributing $11,996,116. The output to date is $258,786,653.

Lake County (Leadville)

At 470 ft. in the Penrose shaft of the Down Town company, a station is to be cut for two electric pumps. The water in the mine will not be lowered further until this work is finished.——The zinc smelter is producing five tons of oxide daily, averaging over 75% zinc.——Thirty tons of $20 gold ore per day is again being extracted from the Big Four on Breece hill.——The Jacketts lease at Ibex No. 1 is shipping 100 tons of 40% carbonate ore monthly.——In the Birdseye district, G. Scheunemann and others are driving a 200-ft. adit at the Key mine. Other work has been done, and good results are expected.——Installation of electric motors at the Fortune mine in Big Evans gulch is completed.——The Mt. Champion mine is producing a good tonnage of rich gold ore. Three to four teams are hauling it.——The Ponsardin lessees so far have not arranged for the sale of their zinc sulphide recently discovered.——Extensive development continues at the St. Louis-Colorado property at Lackawanna. From the Lackawanna Belle, near by, rich gold ore is being shipped.

San Juan County

Shipments of ore and concentrate from the Silverton dis-



PART OF COLORADO.

trict in June totaled 109 cars. Of this, the Gold King dispatched 42; Iowa Tiger, 24; and Sunnyside, 22.——The American Oil Flotation Co. completed installing its plant at the Silver Lake mill at the end of June.——Snow is melting fast at the higher points, and prospectors will be able to start work soon, especially in the Gold Belt area.

San Miguel County

In the Colorado School of Mines *Magazine* for July, A. F.

Hallett describes the milling of vanadium ore at the Primos Chemical Co.'s plant at Vanadium. The ore contains from 1 to 3% vanadium. Five-ton wagons bring the ore two miles from the mine. After mixing with salt and iron sulphide, crushed in a jaw-breaker, and dried, it is reduced to 30-mesh in a ball-mill. McDougal and Wedge furnaces roast the crushed mixture. The vanadium is converted into sodium vanadate, soluble in water. The roasted material is cooled in conveyors, mixed with a weak solution of sodium vanadate, and run into 5 by 30-ft. vats, holding 100 tons each. The charge is leached with hot water from the furnaces for 36 hours. After the solution is cooled, it is transferred to three 50-ton precipitating vats, precipitation being by means of iron sulphate. The precipitate is recovered in Kelly presses, the mud resulting being dried in a Ruggles-Coles machine. The sacked product is then shipped to a refinery in Pennsylvania.

IDAHO

Ada County

Boise people, with J. W. Cox, own the Red Ledge copper mine on Deep creek. It is 16 miles from the terminus of the Homestead branch of the Oregon Short Line. An adit has been driven 400 ft. in ore. A great length averaged 4% metal. According to C. T. Barringer, the property can be best worked by steam-shovels.

Lemhi County

About 2000 tons of ore was sold during June by the Pittsburg-Idaho mine at Gilmore. The ore averaged 30% lead, 10 to 14 oz. silver, and a little gold.

Shoshone County (Coeur d'Alene)

About 5000 men are now employed in the Coeur d'Alene mines and mills.——On July 20 the Success company will distribute 4c. per share, equal to $60,000. Liquid assets total $264,600. Shipments in June were $168,803 zinc concentrate, and $12,066 lead concentrate.——At the old Keating mine near Wardner, the East Caledonia company has unwatered the 400-ft. shaft. Extensive development is to follow. The property is well equipped.——The Stewart dividend is 25c., instead of 30c., as given in the PRESS of July 10.

A drilling contest was held at Wallace on July 4, with the following results: Four teams were entered for the $500 prize. Kinsella and Leaf, from the Tamarack & Custer mine, won the first prize of $350, by drilling 34 11/16 in. in hard granite; Rossman and Haff, with 33⅞ in. to their credit, took second money; St. Germain and Morrison, the Osburn drillers, were third with 33⅜ in.; Stokes Bros. of Moon creek, drilled 32⅞ in. Entrance requirements demanded a residence in the district, thus insuring local men for the contest. In the 'mucking' contest, Campbell and Jones captured first money, eight teams competing. Their time was 1 minute and 10 seconds. Anitila and Jantii stood second with 1 minute and 25 seconds.

MICHIGAN

Houghton County (The Copper Country)

Copper output of the principal mines in June is estimated as follows:

Mine	Pounds	Mine	Pounds
Calumet & Hecla	7,600,000	Superior	356,000
Tamarack	635,000	Hancock	145,000
Osceola	1,933,000	Isle Royale	780,000
Ahmeek	2,629,000	La Salle	13,000
Wolverine	715,000	Winona	250,000
Mohawk	1,317,000	White Pine	730,000
Franklin	256,000	Quincy	2,057,000
Centennial	276,000	Copper Range	5,150,000
Allouez	850,000	Victoria	240,000
Mass	515,000		

The White Pine mill is treating about 800 tons of ore daily, mostly from No. 3 shaft. The stock pile has been removed. The ore is averaging 40 lb. copper per ton.——The Ahmeek mine is producing nearly 3500 tons of ore daily. The July output is expected to be 2,300,000 lb. copper.

MISSOURI

Jasper County

A statement has been issued by operators in connection with the miners' strike. At the meeting held last week, 90 operators employing 5831 men were in attendance. They claim that the strike was started by new men in the district. They intimidated old hands. The principal mines were paying machine-men $4 per 8-hr. shift at the time of the strike, 60% higher than in 1914. The operators will resume work when they are satisfied that there will be no interference. They will not recognize any union. They are willing to pay wages based on the price of ore.

The strike is over, and nearly all miners have returned to work. They have agreed to accept the wages paid at the beginning of the strike.

Owing to the strike two weeks ago the output of the Missouri-Kansas-Oklahoma region was 3000 tons less last week. The range of prices for zinc-blende was from $85 to $110 per ton. The output was as follows: blende, 4395 tons averaging $101.66; calamine, 94 tons at $58.51; and lead ore, 1168 tons at $59.87 per ton. The total value was $519,100.

At Lawton in Kansas, the new 300-ton mill of the Greenfield & Lockwood Co. was blown down on June 30.

MONTANA

Jefferson County

The adit of the Boston & Montana Development Co. at Elkhorn is in 2000 ft. Cross-cutting has been started for the Central and Idanha veins. The adit will be driven 1000 ft. farther later on.

Lewis and Clark County

The famous Drum Lummon property is again the subject of litigation. This time stockholders of the St. Louis Mining & Milling Co., owners of the Drum Lummon, are seeking to have a receiver appointed to handle the affairs of the company until other litigation in which the company is involved has been settled.

NEVADA

Churchill County

Ninety miles west of Fallon is the Bernice district, from whence Black and Solomon of San Francisco have arranged to haul 100 to 150 tons of antimony ore per month to Fallon, and then by rail to San Francisco. The ore is said to be high grade and free from impurities. The Chapman Smelting Co. has received several lots of it.

Esmeralda County

At San Francisco on July 8 a final settlement was made regarding the Merger Mines Co. The directorate will be reorganized so as to give all interests representation.——At 600 ft. in the Yellow Tiger, it is thought that a winze has been found in which rich ore was opened years ago.——At the Atlanta, the dump at the Merger shaft is growing steadily. Ore worth $42.90 per ton was cut last week in incline raise 1011-A on the vein above 1750 ft. in the Union Jack claim. At 1660 ft. the drift is in 150 ft., showing quartz for the full width.——In June the Florence mine shipped 600 tons of $20 ore.——At the Jumbo Extension six faces are yielding 100 tons of ore per day. The mine continues to develop well. The miners' change-house has been fitted with showers. A connection has been made with the Goldfield Consolidated company's fire system.

At the Fourth of July celebration at Goldfield the following are the results of the drilling contest: doubles won by Collins and Lindquist, 40¾ in., prize $500; second, Hughes and Jelik,

39 1/16 in., $200; third, Schram and Olson, 38 3/4 in., $25 in merchandise. Singles, first, Lindquist, 23 7/8 in., $250; second, Brooks, 19 3/8 in., $100; third, Malli, 18 3/16 in., $12.50, in merchandise.

HUMBOLDT COUNTY

At about 125 ft. from the Nevada Packard north end line, the Packard North Extension has cut 9 ft. of good ore. It is supposed to be an extension of the former's vein.

At Willard, the Faucett-Campbell lessees at the Sheepherder claim have shipped 25 tons of ore to smelters.——Two veins have been cut in the Honey Bee. This property has sent out three cars to date. Results are very satisfactory.——Ore has been cut in the Finland No. 2 adjoining. An adit is in 150 ft. ——Two to seven feet of $30 ore has been cut in an upper adit of the Borland-Hunter lease.——Lessees at the Finland have opened rich ore.——At the Enterprise, 1000 ft. from the Henry Bee, the adit is in 75 ft. A carload of ore is at the mill. ——Numerous other lessees are meeting with encouraging results.

LINCOLN COUNTY

It is stated that shipments of tungsten ore are being made from the Silver Comet mine in the Pioche district. Boston people are interested.

NYE COUNTY

(Special Correspondence.)—The Round Mountain Mining Co. is hydraulicking with two monitors, washing from 1200 to 1500 cu. yd. of gravel daily. Tests have shown a minimum gold content of $1 gold per yard. Operating costs are approximately 30c. Net earnings are estimated by the management at from $33,000 to $39,000 per month, including profits from quartz-mining operations. Sluicing can be conducted during five or six months of each year, after which the reduced water supply will cut down production by 25 to 50%. The deposit was briefly described in the PRESS of June 19. Present earnings are at the rate of 2 1/2c. per share per month. The company has paid dividends aggregating $363,000, and it is announced that distributions will be resumed by the end of this summer.

Round Mountain, July 10.

Owing to the holidays the Tonopah district produced only 8264 tons of ore worth $174,712 during the past week.——A machine-shop is to be erected at the Jim Butler mine, where developments continue to be excellent.——Lessees at 535 ft. in the Midway will probably produce a good deal of ore before long.——A new trial in the Jim Butler-West End case was denied last week by Judge Averill.

SOUTH DAKOTA

LAWRENCE COUNTY

For some time past tungsten ore has been sacked at the Wasp No. 2 mine, a small vein being worked during the extraction of the low-grade gold ore. Several shipments have been made, the last two carloads on July 3 being valued at over $300 per ton. More attention is to be paid to mining this valuable mineral. Other properties in the district are said to contain similar ore.

UTAH

BEAVER COUNTY

During the second half of June the Moscow company shipped 14 cars of lead-silver ore. Eight of these netted $1600 per car. The Cullen shaft is to be sunk 300 ft. deeper. A double-drum electric hoist is to be ordered. About 60 men are employed from 400 to 1175 ft. depth. The mine, in charge of G. S. Wilkin, is in good condition.

GARFIELD COUNTY

On Coyote creek stibnite and oxidation products occur in flat lying deposits in sandstone and conglomerate. The ore is found in lenses remarkably free from gangue; these have been worked at irregular intervals since 1880. In 1906 the Utah Antimony Co. erected a concentrator and maintained a fair production for a few years thereafter.

SALT LAKE COUNTY

At Midvale the U. S. Smelting, Refining & Mining Co. is enlarging its mill. The present concentrators and Huff electrostatic plant can treat 350 tons per day. This will be increased to 600 tons. About $75,000 is being spent in improvements. The copper furnaces are still idle, having been so for eight years.

The Bingham & Tooele Mining Co. has resumed driving its adit. It will be 2000 ft. long, where it will be at a vertical depth of over 1500 feet.

SUMMIT COUNTY

Park City mines last week shipped a total of 2836 tons of ore.——The holdings of the Grasselli Chemical Co. at Park City have been bonded to C. C. Broadwater of the Merrill Metallurgical Co. of San Francisco. A large tailing dump is to be treated by the lessees.

WASHINGTON

PIERCE COUNTY

Owing to the increased deliveries of copper ore from Alaska, the A. S. & R. Co. contemplates enlarging its smelter at Tacoma.

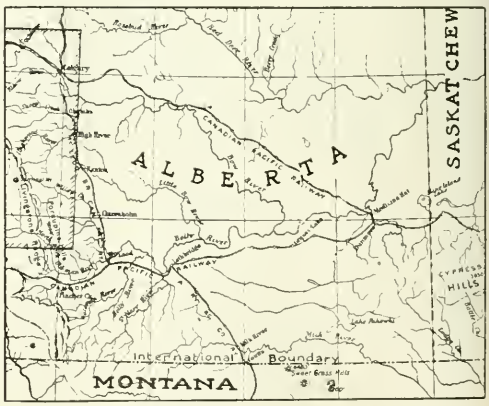
STEVENS COUNTY

Last week the Spokane Chamber of Commerce-Mining Men's Club visited the Chewelah district. At the United Copper mine it was seen that the ore-shoot had been opened for 1225 ft., where it is from 2 to 20 ft. wide. Two raises have connected the 600 and 1000-ft. levels. Sinking to 2000 ft. will be started in September. The oil-flotation process at the mill is recovering 90% of the metal-content, and 95% is expected later. By August 1 the plant will treat 300 tons of ore per day. Generally the property is in excellent order.

CANADA

ALBERTA

The correlation and geological structure of the Alberta oil-fields is discussed by D. B. Dowling in Bulletin 102 of the A. I. M. E. The principal difficulty experienced in correlation



OIL DISTRICTS OF ALBERTA AND MONTANA.

was in connection with the measures known as the Montana group. In Dakota and Manitoba this consists of a series of shales of marine origin. In the eastern Montana section two sandstone members appear, leaving a shale member at the top, and another near the bottom. In the section in western Mar-

tana the lower shale is not found, and the upper one is reduced in thickness. The eastern and western sections have been correlated by tracing them to the international boundary, and making a connection by means of the formations on the Canadian side. The Dakota sands and Colorado shales are described, including their occurrence in the Sweet Grass hills. Structure and development of the region is also discussed.

British Columbia

The smelting plant of the British Columbia Copper Co. at Greenwood is described in Bulletin 103 of the A. I. M. E. up to the outbreak of war. It was successfully smelting in one 51 by 240-in., and two 51 by 360-in. blast-furnaces the lowest-grade copper ore of all plants in America. In order to do so, it had to run at very high efficiency, which necessarily required a large tonnage per square foot of hearth area, together with the minimum amount of labor and other costs. The furnaces smelted daily 2250 tons of ore (6.62 tons per sq. ft. of hearth area), containing 0.85% copper, at a smelting cost of $1.18 per ton. The entire plant required 130 men to operate it and keep up repairs, showing a labor efficiency of about 17.5 tons per man per day. With illustration and plans the paper covers 20 pages.

The Standard Silver-Lead company's new contract with the Trail smelter makes a reduction of $1.333 per ton in the treatment charge and receives 5½c. per pound for lead, against 4c. under the former agreement. The total freight and treatment charges are $8 per ton.

The Fisher Maiden zinc-lead-silver mine, near the Standard, has been leased to the Lippert Investment Company.

The Quatsino Copper Co., operating on Vancouver island, has acquired under bond some more property for $100,000. The company is spending up to $10,000 per month in development of its claims. A railway will be constructed from the mines to June landing on Quatsino bay.

Ontario

During the first quarter of 1915 the McIntyre mine yielded gold worth $177,261, from 23,445 tons of ore, an average of $7.57 per ton. Costs were $5.02 per ton, and profits were $59,482. The average value is $1.43 lower than in 1914, when 62,209 tons was treated with a profit of $158,748. The second quarter should show a better result than the first. Development continues from No. 4 and 5 shafts. Sinking is still under way.

The report of the Buffalo Mines Co. covers the year ended April 30, 1915. The manager, T. R. Jones, stated that development amounted to 2415 ft., and 40,363 sq. ft. of stoping. There was broken 45,237 tons, of which 39,455 tons were hoisted. Reserves of mill ore provided 12,212 tons. Ore reserves are estimated at 16,097 tons broken, and 26,000 tons in place. The ore contains about 20 oz. per ton. The mill treated 51,667 tons, averaging 19.5 oz. per ton. Including sales of silver and metal on hand (125,000 oz.) the output was 822,793 oz. The income was $372,260, and profit $79,690. No dividend has been paid since July 1914; the total to date is $2,807,000.

MEXICO

Sonora

A flotation plant is to be installed at the Cananea Consolidated mill by David Cole of the Arizona Copper Co. This will reduce losses in the tailing.——When the Nacozari railway resumes, the Nacozari Consolidated company will start shipments of zinc-lead-copper-silver-gold concentrate. This will probably go to El Paso, according to the general manager, J. G. Alexander.

The Calendar of the University of Western Australia, at Perth, for 1915 consists of 361 pages. This institution is one of the newest universities, commencing actual work in 1913. There are eight professors, four lecturers, and four assistant lecturers. The third term begins on August 30. Full instruction is given regarding courses, examinations, and degrees.

PERSONAL

W. H. Weed is at Butte.

Charles Janin is in Montana.

Scott Turner is at Petrograd.

W. B. Winston has gone to Denver.

William Braden has returned to Chile.

Howard D. Smith is at Oatman, Arizona.

J. T. Milligan is here from Cripple Creek.

J. W. Malcolmson is here from Kansas City.

H. H. Webb is expected here from New York.

C. A. Demand has arrived here from Mexico.

Howland Bancroft is at the Copley Plaza hotel, Boston.

Stephen Birch is at the Kennecott copper mine, Alaska.

Rensselaer H. Toll is in charge of a mine at Carson Hill, California.

E. S. McCurdy has returned from San Bernardino to Angels, California.

H. C. Hoover and M. K. Shaler have returned to London from Belginm.

W. J. Loring is making a visit of inspection to the Plymouth mine, California.

Bernard M. Baruch, of New York, has been visiting the Utah copper mines.

H. C. Goodrich, chief engineer to the Utah Copper Co., is on a holiday at Los Angeles.

J. Parke Channing, who has been in attendance at the flotation suit, has gone to Montana.

Edwin C. Holden, professor of mining in the University of Wisconsin, has been visiting the Exposition.

Bert Lunceford, for eight years superintendent of the Tom Reed mine, at Oatman, Arizona, has resigned.

F. R. Lynch succeeds W. L. Honnold as local manager for the Consolidated Mines Selection Co. at Johannesburg.

W. L. Wotherspoon, mechanical engineer to the Canadian Mining & Exploration Co., has been visiting the copper mines of the Southwest.

W. L. Honnold left Johannesburg on May 27, having resigned numerous important appointments previous to his return to the United States, after 13 years of honorable and profitable sojourn in South Africa. At the meeting of the Brakpan, Springs, and Transvaal Coal Trust companies he received a cordial valedictory. As consulting engineer, and subsequently managing director and chairman, he is given credit for the success of these important mining enterprises. Mr. Honnold has been on the Rand 13 years; he is a graduate of the Michigan College of Mines. We venture to add that Mr. Honnold's departure was the cause of added regret because it involved that of his capable and charming wife.

Schools and Societies

The University of Pittsburg has issued its announcement series for the School of Mines for 1915-1916. The first division of the semester commences on September 27. The bulletin describes the equipment, admission, courses, degrees, and faculty.

The A. I. M. E. meets at San Francisco on September 16, 17, and 18. There will be excursions to oilfields, dredging, deep mining, and hydro-electric plants. Papers accepted for presentation include five on mining, one on mining law, six on geology, three on milling, four on copper, eleven on gold and silver, four on lead, five on petroleum and gas and four on iron and steel, and four miscellaneous. A joint session will be held with the American Electro-Chemical society. A branch of the A. I. M. E. has been organized at Bisbee, Arizona.

THE MARKET PLACE

Weekly Summary of Metal Prices and Notes on the Markets.

Metal Prices

San Francisco, July 15.

Antimony	35 —35¾
Electrolytic copper	20½—20¾
Pig lead	6.00— 6.95
Quicksilver (per flask)	$95
Spelter	22 —22¼
Tin	41 —42½
Zinc-dust, 100-kg. zinc-lined cases	38

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, July 15.—The copper market is lifeless; lead is very uncertain; spelter is quiet with freer offerings.

COPPER

Prices of electrolytic in New York, in cents per pound.

June	13.60	19.75	Dec.	12.75	....

Exports during the week ended June 26 totaled 7,171,707 lb., worth $1,294,935. Of this, England took 3,859,650; France, 2,477,231; Denmark, 672,000; and Holland, 110,499 lb. Imports of all kinds amounted to 5,656,831 lb., valued at $797,158. Of this, 1,933,250 came from Chile, 1,781,212 from Japan, and 1,129,372 from Peru.

Stocks in England and France on June 15 were 25,674 tons. There was also afloat from Chile to Europe 550 tons, and 4000 tons from Australia.

Lake Superior copper mines are now producing at the rate of 324,000,000 lb. per year, 40% greater than in 1912, a normal year. In a few weeks the output will be at the rate of 360,000,000 pounds.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date		Average week ending	
July 8	47.50	June 2	49.40
" 9	47.62	" 9	49.35
" 10	47.75	" 16	49.31

May	58.21	49.87	Nov.	49.12	....
June	56.43	49 03	Dec	49.27	....

Silver quotations during the past week are self-explanatory. On July 10 about 500,000 oz. left San Francisco for China. The Nipissing at Cobalt last week shipped 249,559 oz. to London via New York. Exports from London to June 23 of 1915 and 1914 were worth £2,619,000 and £3,915,000 respectively, about 13,000,000 oz. less. Stocks in London total about 17,000,000 oz. Advice from London dated June 23 states that offerings were on a rather larger scale, but the support, mainly from India, was limited. The rainy season opened favorably. Later rains are of far more importance to the Indian crops, so the price of silver has not been affected yet.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending			
June 16	90.00	June 30	95.00

May	33.29	39.28	Nov.	33.51	....
June	30.72	40.26	Dec.	33.60	....

According to L. Vogelstein & Co., the tin position at June 30 was just 100 tons different to that of the same date of 1914, namely, 15,927 and 16,027 tons supply, although there was an alteration in holdings as follows:

Country.	1915.	1914.
London	6,136	10,737
Holland	62	1,188
United States	9,729	4,102
	15,927	16,027

Of the totals, 11,166 and 7251 tons, respectively, was afloat. This change shows the magnitude of the American interest in tin supplies, the War resulting in shipments direct to home ports instead of via London. On the whole, considering what the market has been through, the situation must be regarded as favorable.

ANTIMONY

The market has weakened a little under the influence of slightly heavier arrivals, but the spot price still ranges from 36.25 to 36.75c. Otherwise no feature of interest is observed.

ALUMINUM

This market is strong at 32 to 33c. on new business.

Eastern Metal Market

New York, July 9.

All of the metals, with the exception of spelter, have experienced a dull and uninteresting period since the last report. In spelter there was no great amount of buying, but there was enough in a steady, quiet way to maintain quotations. Resale lots of copper have appeared at lower prices, but despite the concessions consumers have been almost inactive. Lead has had its ups and downs, but most of the cheap lead has been taken up by dealers, some of whom predict 6c. lead in the near future. Tin has been dull throughout the week; consumers are well supplied, the large arrivals in sight have weakened the market. Antimony is a trifle weaker, but prices are nevertheless well-sustained. Aluminum is strong.

The steel industry continues to make big gains, reports from every direction being optimistic. Another large gain in pig-iron production was shown in June. In 30 days the output was 2,380,827 gross tons, or 79,361 tons per day, a gain of 6346 tons daily over May. Of the increase, steel-works furnaces contributed nearly 4500 tons. The month brought 12 additional furnaces into blast. The War business is steadily gaining greater headway. The American Can Co. is the latest great corporation to consider entering contracts for supplying munitions of war. The total number of companies now engaged in that work in the United States exceeds 100. The number supplying miscellaneous supplies to the warring countries is many times greater. It is interesting to note that some of the shell contracts now offered have three years for completion. War business with Italy is now in prospect. A commission from that country is now in the United States.

COPPER

Sales have been few and small, and the entire attitude of the market has been one of waiting. Naturally, under such conditions, prices have softened. The producing interests continue to quote around 20c., full terms, for electrolytic, but second-hands have offered and sold copper as low as 19.50c., cash, New York. The London market has been weak and irregular for some days, with especially sharp declines in standard or 'paper' copper. Between spot standard and electrolytic there is a difference of £15 17s.6d. Yesterday there were reports that a few round lots had been purchased by France on approximately the basis of 19.87½c. cash, New York, but if such sales were made they are yet to be verified. The consumption for purposes of war continues heavy and must become heavier as the output of munitions increases. The consumption of metal in the arts of peace is far from satisfactory, though some improvement has been shown in this direction of late. High-grade Lake is quoted at 22.50c., with less desirable grades quoted down to 20c. Exports July 1 to 10 total 3977 tons.

ZINC

A steady business has been done in spelter, both in nearby deliveries and in positions running into 1916, and this fact together with the difficulty in finding prompt metal has sustained quotations and within the last day or two caused them to strengthen. On July 7, for instance, sales were made at 22.50 to 23c. In some ways the present high price is hurting business at large. There are the galvanized-sheet mills which have suspended operations pending a return of spelter prices to more normal levels. Not only is the situation bad for mill labor, but there are cases where the mills have held up certain contracts for their needs until they can resume business. Then again, with galvanized sheets at a high figure their use is minimized and the jobbers suffer a falling off in their trade. Many complaints are heard. Brass-mill spelter is quoted at about 24c. for August delivery, and 25c. for last quarter. Very choice brands are practically out of the market. Some zinc concentrate produced from ore mined in the northern part of the state of New York is now being shipped from St. Lawrence county. The shipments have not reached large proportions. In the first 10 days of this month exports amounted to 1008 tons.

LEAD

An easier trend has developed in the past two or three days and, while the A. S. & R. Co. has held to its quotation of 5.75c. New York, other sellers have offered concessions of 10 to 15 points. Prior to this development the market had gained in strength, and the re-sale lots which had made prices so irregular were bought up. It is significant that much of the buying was on the part of dealers. Export sales are blocked by the fact that the London price is below New York parity. There are those in the trade who predict 6c. lead before very long. Exports up to July 10 were 642 tons.

TIN

The course of quotations for spot Straits has been almost steadily downward. It was quoted July 8 at 38.50c., and there were lots to be had at a still smaller figure. The demand has been light and almost entirely for small lots of spot. The fact is that consumers are well supplied under the contracts they entered some weeks ago. The lack of demand and consequent pressure to sell brought about the decline referred to. A feature of the situation is the large quantity afloat, 7150 tons. The arrivals this month aggregate 950 tons.

Holdings of Guggenheim Exploration

As the Guggenheim Exploration Co. had nearly $12,000,000 surplus, a large special distribution was expected. So far, however, no announcement has been made. It was rumored that the company had been liquidating some of its holdings of copper shares with intentiou of distributing the proceeds among stockholders. It is authoritatively stated that not a share of any of its holdings has been sold. The company's most valuable asset is its 404,504 shares of Utah Copper. Market value of this stock on July 2 was approximately $27,500,000, or more than $2,000,000 above the value of all other stocks held by the Guggenheim company. Yukon Gold shares stand next in value on account of the large holdings, which exceed 2,842,000 shares.

A tabulation of the company's assets made a few weeks back, when the securities market was higher, gave a book-value to Guggenheim shares of $78.90. On the basis of the July 2 market quotations the book-value is lowered to approximately $77.70, the market prices being put at round figures for convenience of calculation. Roughly the distributable value of assets has declined $1,000,000 by the stock market's recession, the value now being $64,627,479 for the 831,732 shares of Guggenheim Exploration outstanding. Holdings are as follows:

	Shares.	Approximate price.	Market value.
Utah Copper	404,504	$68	$27,506,272
Chino Copper	97,750	45	4,398,750
Ray Consolidated	154,300	24	3,703,200
A. S. & R. com	69,500	79	5,490,500
Smelters Securities pfd. A	33,656	84	2,827,004
Yukon Gold	2,842,625	2¾	7,817,218
Alaska Yukon properties and equipment			1,047,262
Cash and demand loans			*11,837,273
Total			$64,627,479

*December 31, 1914.

A new high record in income will be set this year.

BOOK REVIEWS

The Overland Route: a Guidebook of the Western United States. Bulletin 612. U. S. Geological Survey. Ill. P. 244. Price, $1.

This is one of four books to be issued by the Geological Survey with a view to giving scientific information to travelers on the transcontinental lines of railroad. They are based on the data contained in previous geological reports, plus unpublished information, supplemented by a special field-examination by officers of the Survey. The present volume is credited chiefly to Messrs. Willis T. Lee, Ralph W. Stone, and Hoyt S. Gale. No less than 29 accurate maps are interleaved, besides numerous photographs, geological sections, and sketches. The foot-notes are so absorbing that the reader lingers on his way, as at one of those Harvey "eating houses" (what a term!), or railroad-hotels, that used to cheer the traveler in the days before the pretentious Pullman 'diner' came into use. From Council Bluffs to San Francisco the story runs. Lincoln stipulated that the Union Pacific railroad should begin on the Iowa side of the Missouri river, so that the railroad company had to build an expensive, but extremely useful, bridge. At once the geologist gets our ear, for he tells us about the fossils of pre-historic animals uncovered in the gravel through which the railroad grade has been cut. Before we finish with that absorbing foot-note we have gone to Siberia and seen the real fleshly mammoth that was discovered there, held in cold storage by the ice for years untold. Nebraska is "a State without a mine," as if to emphasize the fact that the other states traversed are so rich in mines: Colorado, Wyoming, Utah, Nevada, and California. The mere names trumpet their fame as mineral regions. In the earlier hours of his journey, the traveler's attention is directed to the boulders and vagrant fragments of rock that indicate deposits of glacial origin; whereupon his imagination is quickened by a brief outline of the Great Ice Age and he is given a map that marks the limits of the ancient ice-sheet. From the car-window he sees the southern fork of the Overland Trail that the railway followed and that the western part of the Lincoln Highway is also to follow. This transcontinental automobile road will be 3389 miles long and will traverse 13 States. The work of improving the road is under way. Beyond Cheyenne the sale of fossils suggests the great finds of these beautiful relics of a by-gone period that have been made in the bluffs of the Laramie foothills. A note, with illustrations, describes the extinct animals that flourished in the Miocene period. Then come the coal-fields, with Green River, from which Major Powell started on his famous expedition to explore the canyons of the Colorado. In Utah the geologic history of the Salt Lake arrests the traveler, who is told a great number of interesting facts in such an engaging way that he forgets that it is science that he is imbibing in large draughts. Indeed, the note on Salt Lake is an admirable précis of accurate information. As the railroad nears the various mining centres, the guidebook tells a little of their history and production; it outlines the salient facts in the civic development of this vast mineral territory; it sketches incidents rich in human interest. Many of the photographs are beautiful; some of them are accompanied by diagrams that elucidate the relation of the landscape to the underlying geology. It is an excellent performance. Those who expect to go 'overland' should read this book as an instructive preparation for intelligent travel; those who have crossed it so many times that they have ceased to count their traverses will rejoice that so much useful knowledge should now be readily available to the observer along the well-worn trail that the buffalo, the Indian, the fur-trader, the Mormon, the immigrant, the train, and the automobile have followed successively.

Materials of Construction. By Adelbert P. Mills. P. 658. Ill., index. John Wiley & Sons, Inc., New York. For sale by *Mining and Scientific Press*, San Francisco. Price, $4.50.

This work is primarily a text-book, but, notwithstanding the necessarily brief treatment that must be given to each subject, has also considerable value as a book of general reference. The materials of masonry construction are first considered, the chapter headings being Gypsum Plasters, Quicklime, Hydrated Lime, Puzzolan Cements, Natural Cements, Portland Cement, and Concrete. The production, properties, and uses of each material are briefly discussed. Stone and then brick masonry are then considered, the latter subject including special kinds of brick, terra cotta, and tile. Iron and steel are naturally given the largest space in the book. Methods of manufacture of the different grades of iron and steel are discussed and considerable space devoted to the effect of different proportions of carbon and other foreign substances on the properties of the finished product. In this and also in several succeeding chapters these effects are shown graphically in a number of diagrams. A chapter is devoted to the various special alloy-steels for which the needs of certain modern machinery has created a demand. The different non-ferrous metals that are of importance in construction, together with their alloys, are briefly considered. The last chapter of the book is devoted to timber, the data contained being mainly abstracted from the many government publications on the subject. While the volume as a whole contains little that has not already been said in other books, yet it is several years since all this information has been collected under one cover, and in the meantime, considerable progress has been made both in the production and the use of many structural materials. The book is well illustrated and there are a number of useful tables and diagrams included in the text.

Design of Steel Bridges. By F. C. Kunz. P. 461. Ill., index, and 52 plates. McGraw-Hill Book Co., Inc., New York. For sale by *Mining and Scientific Press*, San Francisco. Price, $5.

This volume is intended more as a reference and hand-book for the practising engineer than a textbook for the student, although the theoretical foundation for design is considered as well as practical details. The first chapters take up the forces acting on a bridge, and then stresses in trusses and in the bracing of simple spans is considered. The various types of bridges are classified and their principal characteristics described. A chapter is devoted to floor-design, both of railroad and highway bridges. Beam and plate-girder bridges, simple truss bridges, and skew bridges are discussed in order, and data are also given on weights of simple span bridges. Viaducts and elevated railroads are discussed, and then draw-bridges and turntables. Arch-bridges both of the two and the three-hinged type are discussed, and also cantilever bridges. Some space is devoted to a general discussion of long-span bridges, although suspension bridges are not thoroughly discussed. The appendix contains some tables and other useful information, and there are 52 full-page plates, most of them showing details of bridges actually constructed. There are also a number of valuable tables and diagrams scattered through the main body of the text.

The Railroad Taper. The theory and application of a compound transition curve based upon thirty-foot chords. By Lee Perkins. P. 356. Illustrated. John Wiley & Sons., Inc., New York, 1915. For sale by the Mining and Scientific Press. Price, $2.50.

This is the second railroad book to be reviewed within the past few weeks. As its name implies, the subject is technical and mathematical, and of value to railroad construction engineers. Elevation of the outer rail on a curve is of great importance. The work is an extension and elaboration of that published by W. Hood, some years ago. The book includes 294 pages of tables.

COMPANY REPORTS

ALASKA MEXICAN GOLD MINING COMPANY
ALASKA TREADWELL GOLD MINING COMPANY
ALASKA UNITED GOLD MINING COMPANY

Reports of these companies for the year ended December 31, 1914, are to hand. They contain a great deal of interesting information, and plans of underground workings. All being under the general superintendency of P. R. Bradley, the reports will be considered together. The year's results may be summarized as follows:

Results of operations.	Mexican.	Treadwell.	United—Ready Bullion.	United—700-Ft. mine.
Men employed	159	733	246	
Average wage per day	$3.28	$3.51	$3.49	
Development in Mexican, feet	1,251	3,723	4,275	8,201
Development in 700-Ft. mine, feet	1,263	840	.....	.....
Central development, feet	*2,041	*2,041	.....	*2,041
Diamond-drilling, feet	67	2,581	2,361	1,923
Underground cost, per ton	$1.019	$0.6896	$1.055	$1.23
Mine samples, number	1,693	3,860	1,880	2,083
Average value per ton	$2.93	$2.82	$3.90	$2.60
Reserves in place, tons	327,426	6,604,086	1,835,650	2,359,495
Reserves broken in stopes, tons	361,312	555,167	308,412	182,982
Total reserves, tons	688,738	7,159,253	2,144,062	2,542,477
Average value per ton	$2.68	$2.48	$2.85	$2.22
Reserves in previous year, tons	816,882	6,093,308	1,708,662	1,281,475
Stamps dropping	120	540	**120	120
Steam power used, days	135.25	†118.66	126.09	156.64
Water power used, days	223.70	†236.53	225.04	199.55
Electric power used, days	.....	‡195.37 ‡133.89	.....	.....
Duty per stamp-day	5.42	†4.49 ‡5.34	5.53	5.27
Ore crushed, tons	233,457	910,285	233,100	225,214
Gold by amalgamation	$238,757	$1,264,945	$282,037	$230,510
Concentrate treated, tons	4,341	19,325	5,701	4,409
Gold by cyanidation	$270,267	$1,102,617	$252,371	$200,874
Total recovery	$509,024	$2,367,562	$534,408	$431,384

Dividends (4) (6) (4)	$144,000	$1,100,000	$162,180	
Depreciation	$25,451	$250,953	$81,153	
Balance for 1915	$10,814	$48,680	$15,160	
Returns to date:				
Ore treated, tons	4,053,903	14,778,074	3,428,903	1,856,753
Gold recovered	$10,947,737	$26,332,186	$7,134,914	$3,952,100
Yield per ton	$2.70	$2.46	$2.08	$2.13
Operating profit	$3,997,944	$17,060,377	$1,687,771	$962,598
Operating cost	$1.72	$1.31	$1.59	$1.61
Dividends	$3,417,381	$14,885,000	$1,738,930	

*Done jointly with the other companies. **Now 150 stamps. †240-stamp mill. ‡300-stamp mill.

It will be noticed in the above table that the three companies contributed to the Central development work. This included operations at 1750, 1950, 2100, and 2300 ft. The Central shaft was sunk 83 ft., making it 2354 ft. deep in waste. The Central hoisting and crushing-plant, the former breaking down on June 19, 1915, worked throughout the year. It handled 1,097,770 tons of ore and 6247 tons of waste. New equipment is being installed in the Central steam-electric power-plant. When complete, its capacity will be 4750 kw. The cost was $183,562.

At the Nugget Creek hydro-electric plant $39,000 was spent on the dam and transmission-lines. An addition to the Sheep Creek hydro-electric plant was completed. Large motors were installed at hoists and mills.

The cyanide-plant treated 33,775 tons of concentrate from all the mills. The recovery was 96.86%, at a cost of $2.76 per ton of concentrate treated.

The assay-office made 44,224 determinations at a cost of 23.6c. per sample.

A new general office was erected, extensive alterations to the store, and two new warehouses were built on the Treadwell wharf. The fire department and committee of safety showed their usual interest in their work.

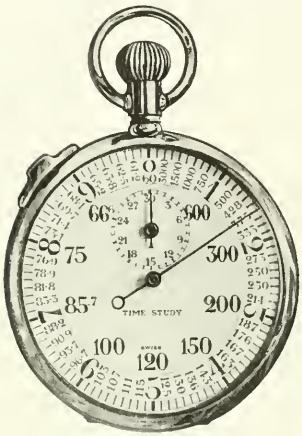
In Bulletin 103 of the A. I. M. E., W. P. Lass describes the electric furnace for gold refining at the cyanide plant. From three to four tons of gold precipitate, worth $40,000 to $60,000 per ton, is produced from the concentrate per month.

New Machines and Devices

Information based on letters and catalogues from manufacturers.

Time-Study Watch

The Time-Study watch, of Mortimer J. Silberberg, Peoples Gas building, Chicago, a photograph of which is shown, gives direct reading in operations per hour, eliminating mental and pencil computation. The dial is divided into tenths and hun-

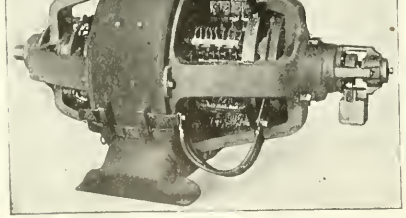


TIME-STUDY WATCH.

dredths of minutes. There are also figures spaced two-hundredths of a minute apart, distinctly legible, that indicate at any point of elapsed time exactly what the corresponding output per hour is. The watch is very convenient for observations of all kinds of work where the study of time taken is necessary.

Rotary-Converters in Coal Mines

According to the Westinghouse Electric & Manufacturing Co. of Pittsburg, it is interesting to note the favorable im-



WESTINGHOUSE ROTARY-CONVERTER.

pression being made by the rotary-converter in coal mining, particularly since the manufacturer has developed the new commutating-pole machine in smaller sizes. One of the chief troubles in mining work, particularly with small rotaries, has been commutation, because the mining load varies anywhere from 10% of full load to 100% overload in a very short time. With the non-commutating pole rotary, it was necessary to shift the brushes with the change in load, or sparking and damage to commutator would result. This damage to commutator would end finally in short-circuited coils and burnouts. Since the application of commutating-poles, a machine normally designed for 35° rise in temperature at full load, will carry a 50% overload for 2 hours with a rise not exceeding 55°, and a momentary overload of 100% without the least sign of sparking, this better performance being due to the application of commutating-poles. With this design the brushes are set on the neutral point and fixed there, and the varying loads have no effect whatsoever in-so-far as sparking is concerned.

An order from the Stonega Coke & Coal Co., Virginia, was for twenty-four 150-kw. converters, to be placed in 12 underground sub-stations. Another installation, above ground, is of 200 kw. at the Conemaugh Smokeless Coal Co., Pittsburg. The accompanying photograph shows this machine. Three sizes of this type are built. Another type is made in 300 and 500-kw. sizes.

Commercial Paragraphs

The Anaconda Copper Mining Co. is preparing to install 24 more of the 10-ft. diameter HARDINGE mills. This makes a total of 44 out of a contract which it made the first of this year for 60 of these machines.

A leaflet issued by the DEISTER CONCENTRATOR Co., Fort Wayne, Indiana, shows facsimiles of telegrams from the Stearns-Roger Manufacturing Co. of Denver, ordering tables for the Ajax mill at Cripple Creek.

Bulletin E-36, superseding E-29, of the CHICAGO PNEUMATIC TOOL Co., 1010 Fisher building, Chicago, deals with the various Duntley electric grinders. They are useful in foundries, machine-shops, structural shops, and for grinding rails on railways. No. 6 is for external and internal grinding.

'Centrifugal pumps and centrifugal pumping units' is the title of Bulletin 1632, 44 pages, of the ALLIS-CHALMERS MANUFACTURING Co., Milwaukee, Wisconsin. Single and multi-stage motor or engine-driven pumps up to 72 in. are made. One mine pump is a solid bronze 10-in. 10-stage machine for lifting against high heads.

The NORMAN B. LIVERMORE & Co., San Francisco, advises us that a Chalmers & Williams adjustable quick-discharge tube-mill has been sold to the California Slimes Extraction Co. at Sutter Creek, California. This will re-grind tailing from some Mother Lode mills. A 24-in. Symons disc-crusher has been sold to the Original Amador company at Amador City. This will reduce the present crusher output to a size for the tube-mill.

The WESTERN ELECTRIC Co., New York, sends us the following circulars: 'The Telephone in China,' (installation at Pekin, Tientsin, Changsha, and Tsinanfu, with 4100, 2450, 600, and 450 subscribers stations respectively in January 1915, all of W. E. manufacture); 'Telephone Cable in China,' (illustrating laying W. E. cable, under direct supervision of W. E. engineers, in Changsha); and details of the awards of the company at the Exposition at San Francisco. The Grand Prix was given for the exhibit as a whole, three gold medals for telephone equipment; two bronze medals for mine-rescue and mine telephones; and silver medals for various electrical devices by companies closely identified with the Western Electric Company.

EDITORIAL

T. A. RICKARD - - - - Editor THOMAS T. READ - Associate Editor

THE American Institute of Mining Engineers meets in San Francisco on Thursday September 16 and for three days thereafter.

MENTION of advertisements on this page is contrary to our custom, but we shall be forgiven, and not misunderstood, by our readers if we direct their attention to an advertisement of smelter-brooms made by the blind, appearing on page 24 of our advertising annex.

PROHIBITION of exports of copper from England, by order of the British government, has eliminated the international influence of the London Metal Exchange in regulating the price of the metal. Thus the American copper producers are now in a position to dominate the market.

MANGANESE production in Russia has been greatly hampered by the War. Two years ago nearly a million tons per annum was exported from the Caucasus, about half of it going to Germany. What the German steel-makers are doing to secure an alternative supply has not been made public.

CURRENCY problems in Mexico threaten to become more pathetic than humorous. In our mining news we give an outline of sundry projects for regulating the paper money issued in Sonora. This should be read in conjunction with the special article on 'Conditions in Sonora' appearing in our last issue.

WORK at the Gary plant of the Illinois Steel Corporation is now on a full-time basis, for the first time in two years. Shipments of iron ore from the Lake Superior district during June show an increase of almost 20% over last year. These evidences of increased activity presage the return of industrial prosperity.

WORKINGS in the Morro Velho mine, in Brazil, have reached a vertical depth of 5826 feet, making it the deepest mine in the world. This depth is not reached by a single continuous shaft, so that the Tamarack No. 5, which is 5368 feet long, still retains its laurels as the deepest shaft in the world. The Morro Velho is owned by the St. John del Rey company, in London.

KOREA is to have a new set of mining laws; these are in process of being drafted by the Japanese authorities. One of the requirements will be that each mining company must maintain a head office in Korea, but this will not affect the principal foreign companies, which operate under special concessions. The gold production of Korea in 1914 is given in a recent consular report as $5,000,000; the mines worked by foreign companies showing an increase of $500,000 in their output, and those worked by Japanese and natives a decrease of $300,000. A strong Australian company has purchased placer deposits in South Ham Kyong province and in South Pyeng An province.

PARCELS-POST as a means of shipment of concentrate to smelters is the novel method of transport described in our news columns, two tons daily being shipped in this way by mines in Clearwater county, Idaho. The cost of the service to the Government is greater than the postage charges, so that it may be regarded as a government subsidy to prospecting.

OIL production continues to expand, despite falling prices. This is shown by the Geological Survey's statistics for 1914, just issued. During last year production increased by 17,316,305 barrels, to a total of 290,312,535 bbl., despite a decrease of $23,006,173 in the value of the output. California retains first place for magnitude of production, with Oklahoma a good second.

SHARES of the New Jersey Zinc Company have changed hands at $940 each. Excepting the Calumet & Hecla, this is the highest quotation reached by the stock of a mining corporation in recent years. The high figures are justified, as the company has this year paid cash dividends amounting to 50%, and will soon pay a stock dividend of 250%, the capital of the company having been increased from $10,000,000 to $35,000,000.

FLOTATION in Mexico is appropriate. A revolution in metallurgy finds there a fitting environment of unrest. In the important article that we publish in this issue it is shown how silver ore is readily amenable to the process and how the resulting tailing can be cyanided satisfactorily. The use of alkaline water in the frothing-cell is another notable point. The detailed results, the items of cost, and the careful comparison between cyanidation and flotation will prove deeply suggestive to metallurgical engineers.

OUR attention has been directed to a misinforming paragraph in the *Examiner*, stating that a large acreage of fertile land in Sierra county, California, is to be ruined by dredging for gold. This refers, presumably, to some ground near Redding recently purchased by Mr. Lawrence Gardella, a good citizen and an enterprising operator. The land to be dredged is not fertile

in its present condition, nor is any of the land now being dredged suitable for farming. Moreover, when the ground has been turned over in the course of digging for gold, it is to be leveled and made ready for cultivation. Olive orchards have been planted in the wake of gold dredging. It is poor economics "to destroy fertile lands in order to get a single quick profit," says the *Examiner*. It is poor economics to spread misinformation.

MINES have a double meaning: one peaceful, the other warlike. Hammond is a name formerly associated with gold mines in Africa and elsewhere; now it is to the front in connection with wireless torpedo-control. We congratulate Mr. John Hays Hammond, Jr., on the inventive skill that has won him such honorable prominence.

OUR weekly letter on the metal market will be found interesting despite the dullness of business. A lull in activity has followed an interval of excitement. We look for another rise in prices at an early date. We commend our market report with confidence, for our representative at New York gives the consumers', not the brokers', price. In short, he gives what the mine-operator wants.

MEXICO CITY is again in the hands of the Zapatistas, while the previous army of occupation is somewhere northward preparing to meet Villa's troops, which have occupied Pachuca. That is important, for the Real del Monte, Santa Gertrudis, La Blanca, and other celebrated mines make Pachuca one of the big mining centres of Mexico. Carranza's men have taken Naco, upsetting the arrangement made by General Scott. On the whole, conditions in Mexico indicate with added emphasis that none of the existing factions is competent to restore order. The establishment of a coalition government, backed by Washington, is the only hope for the country.

SILVER-LEAD ore is being mined in the Yukon. Last week we mentioned the fact of a shipment of such ore having arrived here, for treatment at the Selby smelter. In the present issue we publish a short account of the find, as described by Mr. D. Saunders. In the summary report of the Department of Mines, for 1913, it is stated that "Galena creek, a tributary of the McQuesten river, 11 miles off the road to Dutch gulch, was visited as the result of a reported find of a rich argentiferous galena vein. Reports were, to some extent, confirmed by assays of samples sent by the owners to the Territorial Government assay-office at Whitehorse." This refers obviously to the same discovery, which has now become a mine.

PASQUAL OROZCO, recently of Mexico, we find, has at least one good count to his record. Ten years ago the pay-roll money was being taken from Miñaca to the Dolores mine when the escort was attacked by two American outlaws. The Mexican escort was commanded by Bill Smith, with thé aforesaid Orozco as his chief aid. Three Mexicans were killed and six were wounded, but the thieves were repulsed, one of them being captured and killed subsequently at Casas Grandes. After this episode, in which he behaved admirably, Orozco became conductor in place of Smith and he continued to hold the job until the Madero revolution broke out. Then he organized a band of mountaineers and joined the revolutionary forces, becoming a notable leader in the civil war that has brought Mexico to ruin.

ONE of the surprises of the last two years has been the maintenance of handsome profits by the Guggenheim companies—the American Smelting & Refining and the Guggenheim Exploration—despite the chaos in Mexico and the general depression in mining. The wide-spread energies of the American Smelting company are shown by the fact that of the total lead production in the United States last year—564,000 tons—this company refined 317,000 tons, and out of the total domestic output of 1534 million pounds of copper, the same company refined 530 million pounds. By the big production of the Chile Copper Company, and the increasing yield of the Braden, in Chile also, and the Kennecott, in Alaska, the Guggenheim corporation will become a still bigger factor in the copper business.

INCREASE of richness in depth is an idea pleasant to the miner. We read in a San Francisco evening paper that the ore that assayed $4 at the surface of a certain vein in Nevada increased in value to $19.50 at 90 feet. This is a notable increase. If a baby gains 2 pounds in a week, he would gain half a ton in 10 years, at the same rate. So while we congratulate our friend in Nevada on the improved showing at the bottom of his prospect-shaft, we would not call it an "increase in depth," not yet. At the rate of improvement noted, the shaft would strike solid gold at 800 feet. However, almost anything should be possible in the case cited, for *The Bulletin*—the purveyor of valuable information in question—says that "the deep tunnel is in anthracite, which is a gold formation." Not nearly as good as either Guggenheimite or Jacklingite.

Antimony and Arsenic

We have received letters from several subscribers who seem to be under the impression that arsenic has participated in the rise in price that antimony has shown in consequence of demands created by the War. While antimony and arsenic are closely allied in chemistry, their industrial uses differ widely, and, unfortunately for producers, there has been no marked increase in the demand for arsenic. The metal arsenic has almost no industrial uses. A little is used in the making of shot, but as arsenical lead is used for this purpose no market for metallic arsenic is thereby created. White arsenic, or arsenious oxide, is most in request; it is used in the manufacture of glass, in the making of Paris green, London purple, and other insecticides, such as arsenical sheep-dip, for the preserving of hides, and stuffed ani-

mals, and in the making of other arsenic compounds. The di-sulphide and tri-sulphide, corresponding to the minerals realgar and orpiment, are used as paint, and the former is also consumed in the making of fireworks and in the dyeing and printing of cloth. Other salts of arsenic have a variety of limited uses.

All the arsenic produced in this country is a by-product of lead and copper smelting. The origin of arsenical lead is obvious; white arsenic, to the amount of two or three thousand tons yearly, is recovered from flue-dust by the Anaconda Copper Co., the United States Smelting Co., and the American Smelting & Refining Co. Each of these companies could increase its output if the demand justified so doing. The price of arsenic compounds is so low that freight-costs are important and for this reason a larger quantity is imported from Europe than is produced here, since ocean-freights are much less than railway-rates from the Rocky Mountains to the Eastern seaboard. In Eastern Canada arsenical gold ores are found in abundance, but arsenic production does not flourish. In Mexico the Peñoles mining company was a producer of importance, but its output has been hindered by political conditions. On the whole, the production of arsenic is not an alluring business.

Antimony has had a sensational rise in price because of its use in the making of ammunition. Conditions governing antimony production were discussed in our issue of November 14, 1914. Before the War the market for the metal was controlled by English firms, but the embargo on exports from England made readjustment imperative. The Wah Chang Antimony Co., the principal Chinese producer, took advantage of the terms of the contract under which its output was being sold by a subsidiary of one of the English firms and opened its own agency at New York, with the gratifying result that it soon received more orders than it could make immediate delivery. Within a few months the price of the metal rose to six times what it had been. As a result the Chapman Smelting Co., of San Francisco, re-opened its smelting plant and began bidding for antimony ore from Idaho, Alaska, and elsewhere, and operators in Mexico, where antimony ore occurs in abundance, have begun the construction of a plant at San Luis Potosi that will be in operation within three months. Presumably it will serve to lower sharply the present level of prices, as the proposed output will equal 40% of the normal consumption in the United States. The cost of an antimony-smelting plant is not great, and if the War persists for some time the new producers are likely to make large profits. They can hardly hope to develop an important permanent business, for the Chinese producers are able to supply almost all of the normal demand and have demonstrated their ability to work at a profit at the low prices formerly prevailing. According to consular reports, the exports of antimony from Hankow, China, during 1914, were 10,071 tons of crude and 1384 tons of regulus, valued at $486,916 and $88,874 respectively. Ore and secondary products exported during the same period brought the total value of the exports up to $768,935. Production for the first quarter of this year is reported to be at the average of last year for regulus and four times the normal for crude. The great increase in the price has correspondingly increased the value of exports.

Patents and Secrecy

Anonymity seems to characterize recent contributions to the technology of the flotation process. We have published two useful articles under the veil of occasional correspondence, and in this issue we give our readers, under the disguise of special correspondence, a detailed description of flotation work in Mexico. For this concealment of names we have no liking, nor, it is fair to add, have the clever technologists to whom we, and our readers, are indebted for so much timely information. Such secrecy is the sequel to patent litigation; it is due neither to mock modesty nor to any innate love of the mysterious. Whether a decision in an important case now under adjudication will 'lift the lid' and admit fresh air into the fog enveloping technical research into flotation, we do not know. We only hope.

Not that the latest phase of patent litigation over this process is to be debited with all the blame for the general atmosphere of mystery and jealousy that has distorted the technology of the subject during the last ten years. Apart from the embargo imposed upon the publication of information, the protracted series of conflicts over patent rights has served to lessen the scientific value of even the scanty evidence available, for it has created prejudices and interests so strong as to vitiate the judgment or hinder the pen of the few men willing to write on the subject. On the other hand, it may be admitted that the preparation of testimony for lawsuits and the cross-examination incidental to the giving of evidence in open court have served to clarify the basic ideas underlying the process and its application. Yet we are among many that have expressed regret, repeatedly, that the leading protagonists of flotation, such, for example, as Messrs. Frank Elmore and John Ballot, should not have effected a compromise in the early stages of their controversy. Similarly, we think it a pity that the more recent clash of interest between Minerals Separation and its opponents should not have been obviated by reasonable concessions on both sides. In behalf of the profession we express the pious wish that somebody may evolve a scheme for rewarding an inventor without taxing an industry.

It is not the royalty, or tax in money, that does the injury, but the tax on knowledge. Secrecy is a thick-headed watchman that obstructs the alert steps of progress. At the present time the amount of unnecessary work being done is pathetic, for experiments already tried and attempts previously proved futile are being made in many laboratories, simply because there has been no publication of the results heretofore obtained by other investigators. Similarly, useful hints for obviating recurrent difficulties and fertile suggestions for improving practice are withheld because of the scramble for obtaining dubious property rights to ideas by aid

of the Patent Office. As a matter of fact publicity is often an invaluable protector, in so far as it tends to prove priority of invention or application. Our readers are aware, for example, of the Moore *v.* Butters litigation over the vacuum-filter. Not many of them, however, know that the best proof of priority brought forward by Mr. George Moore was the article on his filter that he published in the *Engineering and Mining Journal* of December 5, 1903. That was written at the solicitation of the present writer, who was then editor of our contemporary in New York. The fact of publication was accepted by the Court as an indication that Mr. Moore's competitor must have been cognizant of the details of the device, on the supposition that he had read the published description. Indeed, a lot of unprofitable wrangling over priority of invention could be obviated by a frank publication of details, as in the case cited. We need only add that our columns are always open to the publication of metallurgical information and we shall be glad to serve as a means of giving guidance to the prospectors of technology. Moreover, we hope that the alert and generous spirits in the ranks of metallurgy —and there are, thank Heaven, plenty of them—will use our columns to add to the accelerating progress of this important process of flotation, by exchanging ideas among each other to the gain of all.

Fine-Grinding

The rapidly growing importance of flotation as a metallurgical process has had the remarkable effect of reversing commonly accepted traditions in regard to fine-grinding machinery. In ordinary water-concentration every precaution must be taken to prevent the production of slime during crushing, as metallic mineral in this form was lost. During the last decade reduction in stages, with the prompt removal of the crushed product from the crushing machine, has become highly developed in consequence of the effort to prevent undesired comminution. In flotation the emphasis lies on other criteria. Slime has no terrors for it; in most cases the process seems to work better if a proper proportion of slime is present; while coarse material, even if consisting wholly of valuable mineral, can be floated only with difficulty. The metallurgical need for stage reduction disappears, and the simplest arrangement in milling would be to have a single machine to reduce the ore to the size desired for flotation treatment. Since, for this purpose, all the ore may have to be crushed to pass 80-mesh, so simple an arrangement is scarcely practicable, but at any rate the necessity for a complicated series of rolls and other crushing devices, with their accessories—feeders, elevators, and screens—no longer exists. In the Inspiration flow-sheet, published in our issue of July 3, the reduction of the ore to pass 48-mesh is performed by a Symons disc-crusher and a Marcy ball-mill in one-half of the mill, and by two disc-crushers and Hardinge mills in the other. It must not be assumed hastily that by reducing the number of machines required, the cost of crushing can be equally decreased. It requires the expenditure of power to crush ore, and of two mechanically satisfactory machines, the one that crushes double the quantity of ore must necessarily use about double the power. Fundamental principles in design must, of course, be observed; a heavy hammer is essential for double-hand drilling, but unsatisfactory for driving tacks. It is for this reason doubtful whether any single machine can give the best results in reducing lump ore to fine sand in a single operation. It is common practice to do this with stamps, but it is well known that the stamp is inefficient in its use of power, nor is it practicable to produce by stamps so fine a product as is desired for flotation without cutting down the tonnage to an uneconomic degree. The tendency of late years has been to allow stamps to make a comparatively coarse product and finish the crushing in some other machine. It is not probable, therefore, that single-stage reduction preliminary to flotation will ever prove feasible. Two or three stages are likely to represent the practical minimum.

The question arises, however, whether the investigation of crushing machines may not be profitably directed along wholly new lines. Such machines accomplish their work either by impact, as in the case of stamps, by pressure, as in jaw-crushers and rolls, by trituration, as in a disc-crusher, or by true grinding. Of the latter an arrastra is perhaps the best example, though every grinding-mill also utilizes one or more of the other forms of action. Such machines as tube-, pebble-, and ball-mills do their work by a combination of impact-trituration, and grinding. Theoretically, grinding is the best way in which to obtain a fine product, while trituration is the best method for securing a granular product: the latter cannot be easily applied to very fine material because of excessive friction between the triturating surfaces. Friction between the working surfaces is also important in grinding machines, leading to waste of power and excessive wear. It is obvious that a machine that grinds away material fed into it is likely to grind away itself. It would appear that the principle of the tube- and ball-mills is essentially sound, since the ore particles are ground against each other as well as against the mill.

The factor of time is also of importance in fine-crushing. Heretofore the aim has been to secure a quick discharge of the crushed product in order to prevent sliming. Now that sliming is no longer feared, the desirability of quick discharge disappears and it may indeed prove that a longer retaining of the pulp within the body of the crushing machine permits greater efficiency because it leads to finer grinding. On the other hand, it is obvious that it is not good practice to attempt to crush 6-inch lumps and 60-mesh sand in the same machine, and it is a waste of power to retain material in the machine after it has been crushed fine enough to escape. Much careful study is being devoted to the fine-grinding of ore by both mill-operators and machinery-manufacturers. A free exchange of information will greatly facilitate the attainment of a satisfactory solution. For this our columns are open.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more vaulable than casual compliment.

Big Business

The Editor:

Sir—Referring to the editorial in your issue of July 10, under this title, some of the examples cited as illustrative of the economic advantages to be derived through huge mining operations appear, upon analysis, to be lacking in essentials. For instance, examine the records of the disseminated copper mines somewhat closely—Utah Copper, Ray, and others mentioned in your statement as shining lights in the mining firmament—not with a view to critieism, but as to economic results attained, and the support they lend to the argument you advance.

Turning back to the PRESS of June 7, 1913, to an article written by Mr. Heath Steele, the actual percentages of metal recovery effected at some of the large copper properties are given as follows:

Name of mine.	Year.	Actual recovery.
Utah Copper	1910	55.6
" "	1911	59.9
" "	1912	57.4
Miami	1911	66.7
"	1912	61.0
Ray	1911	50.6
"	1912	51.2
Nevada Consolidated	1910	70.0
" "	1911	69.5
" "	1912	66.0
Chino	1912	55.0

In the article mentioned, Mr. Steele points out that the quarterly mill-recoveries reported by the various companies are misleading, and he gives the reasons for this statement. Possibly extraction may have been improved since Mr. Steele compiled these figures; but during the period covered by his record these examples of efficiency on the part of big business (at least as applied to mining) can hardly be referred to as satisfactory. The records made on these properties for the years given might even be considered by economists an extravagant waste of national resources.

This copper has been taken out and sold, largely to foreigners, at an alleged profit of from two to three cents per pound (*Mining & Engineering World,* May 8, 1915, page 863), and in doing this nearly two pounds of copper have been wasted for every three pounds recovered. It must also be remembered in this connection that copper minerals contained in the tailing run out from mills handling 'disseminated' ore, have been irrevocably lost, for, exposed to atmospheric agencies in their existing fine state of division, sulphates are formed which are carried off in the rains.

Considered purely from an economic standpoint, the country would have been the gainer if this copper had been left in the ground until methods were devised for effecting a reasonably high recovery. In well organized communities—Germany, for instance—in all probability the Government would intervene where exploitation of national assets is undertaken in the crude manner often practised in this country.

Nor can it be conceded that very large operations are profitable to the shareholders upon capitalization represented by stock quotations. Because an enormous quantity of cupriferous material is rushed through mills, and sufficient copper is caught to pay temporary dividends, the actual outcome of such operations will not be known until the books are finally balaneed upon exhaustion of the deposits.

An interesting sidelight upon the relation of large corporations to exploitation of 'disseminated' orebodies was obtained last year when the output was said to have been curtailed 50%. With this greatly diminished yield some of the companies claimed that their costs of production did not differ much from what they had been when the properties were operated at capacity.

The facts enumerated tend to diminish the alleged economic advantages of spectacular mining, and produce a lingering suspicion that something remains to be said in favor of operations upon a lesser scale, conducted with more regard for the balance-sheet and less for the stock-market..

As to the further example you mention in favor of big business in mining, the advantage of having 100 stamps upon a single consolidated property, crushing 5 times as fast as a dozen 40-stamp mills on individual mines, why should a stamp in a 100-stamp mill crush 5 times as fast as one in a 40-stamp mill?

A certain number of stamps can be properly supervised by one battery-tender: the number of such units under one roof does not materially affect the economy with which the mill can be operated, although, of course, expenses in some departments can be reduced somewhat in the larger mill. In looking over records for cheap milling of low-grade ore, striking examples are found among those made by small mills, and it is open to question whether the very large mills have at any time exceeded these records. It is not disputed that such large operatione as the Homestake and Treadwell are brilliant examples of practieal mining and metallurgy; but would

not the same management have achieved equally commendable results had it been in charge of smaller properties?

In any event, the dozen 40-stamp mills mentioned by you distribute more money among the communities in which they are operating than does the single large mill, even if it should crush faster. And the slower-crushing mills do not exhaust the mines as rapidly; all of which tends toward betterment in mining communities, increases subscriptions to the Mining and Scientific Press, and encourages advertisers.

As to the assistance rendered by big business in the development of prospective mines, and we all known that mines must be made from prospects, reference again to the pages of the Press is instructive. In your issue of April 10, 1915, p. 592, it is stated that during the year 1913 there were 639 mining properties submitted for investigation to one of the large mining corporations. Of these, all but 101 were rejected on examination of the data and reports, and then 82 of the 101 failed to stand up under preliminary field-examination. Of the remaining 19, two were taken, and a long-time bond was secured on a third. This record is typical of the operations of other large companies. It means that out of 639 prospects brought to the attention of a giant corporation, 636 were considered unsuited to the requirements of big business, which fact, however, does not necessarily condemn them as prospective mines. Big business calls for big mines, for to advance stock quotations large quantities of metal must be produced. But what is to become of the small deposit? And how are prospects to be developed under the régime of megatheric corporations? There are far more comparatively small ore deposits than large ones, and exploitation of the small ones—those which are not large enough to stock and put on the market—must become a matter of increasing importance as the larger mines are exhausted, and prices of the metals advance in consequence.

One of the principal representatives of big business in mining was recently quoted as saying: "Unfortunately, the mining industry cannot see where in the next ten years any more substantial producing mines are to come from." If this forecast proves to be correct, the necessary metals will have to be supplied at an advanced price from small mines operated by individuals, or small corporations, and such a state of affairs will not be detrimental to the mining industry.

W. L. Austin.

Riverside, July 12.

The Waste of Zinc

The Editor:

Sir—During the last few years we have read a great deal regarding the necessity for conserving the coal and timber resources of the United States. It should be realized by our Government that there is equal need for preventing the unnecessary waste of our metals.

The improved methods of concentrating copper minerals has enabled companies (having sufficient capital to operate on a large scale) to handle very low-grade ore, in some cases averaging less than 1½%, profitably, even with losses as much as 40% of the copper. Heavy losses must be expected, of course, when treating such low-grade ore as is now being mined in Utah, Arizona, and Nevada. The percentage of loss of either lead or copper in the treatment of low-grade ore is necessarily much higher than when treating high-grade ore, for where there is only a few pounds of metal to be extracted, the weight of the remaining waste is much greater, so that even if the waste to be thrown away is as clean in one case as the other, the most waste would carry off the most metals to be divided by the smaller weight of metal in the original ore. This is easily explained, but seldom appreciated by the mine-owner.

The introduction of the bag-house and Cottrell's system of saving the fume and dust, at copper smelters as well as at lead smelters, has reduced the metallurgical loss in that department, but, with all the improvements in copper mining and reduction, how long will the supplies of such ore last? Mr. D. C. Jackling has been quoted as asserting that, at the present rate of production, there are no known sources of supply capable of meeting the world's requirements for the next 20 years.

[This reminds us that James J. Hill once ventured a similar prophecy as to the supply of iron ore.—Editor.]

Mr. Jackling is, I believe, right; but the question of a zinc supply is no less important. The loss of zinc, in its recovery from the original ore, is much higher than the losses of other metals, while no attempt is made to recover the zinc from ores as poor as the copper ores that are being treated successfully. The statement has been made that the average recovery of zinc from ore is 51%. This poor recovery is no doubt partly due to the large amount of low-grade zinc ore mined and concentrated throughout the Mississippi Valley states.

The loss of zinc, when smelting zinc concentrate, is greater than the loss of lead and much higher than the loss of copper in copper smelting. The greatest waste and a double loss to the mine-owner, is not only the loss of the zinc, for which he gets nothing when contained in an ore treated for other metals, but the penalty he has to pay on account of the zinc. This is illustrated in the following example.

The miner sends his ore to a custom smelter; this ore contains, say, 20% zinc. The regular penalty is 50c. per unit above 10% zinc. The value of 85% of this zinc, 340 lb. @ 5c. is $17, which is lost.

Now he pays a penalty on this ore of $5, the usual treatment charge on lead ore of $8, and if a sulphide ore, a roasting charge of $2, making a total penalty and treatment of $15, in addition to the loss of the zinc. With few exceptions, 80 to 85% of the zinc in such ore can be recovered in addition to lead or copper, with gold and silver, for a smaller cost than the combined treatment and penalty now charged where the zinc is wasted.

I am not criticizing the custom smelter for penalizing the zinc in the ore, especially the lead smelter, knowing too well the trouble the zinc causes them, by helping to form incrustations on the walls of the furnace and in the

lead crucible, carrying other metals into the slag and adding to the lead-silver losses by volatilization.

The great waste of zinc throughout the West starts in the mine, where it is left. If broken in order to get out the other ore, it is thrown over the dump as waste or left in the fills to be perhaps forgotten or left until the mine has been abandoned, when it will not pay to re-open the mine to get at it.

Now, as the consumption of zinc is increasing, as its value is more fully appreciated, I would like to know how long our zinc mines will last as compared with the copper mines that can be worked to great depth?

There is no doubt in my mind but that most of this zinc waste can be avoided. Whenever the zinc is recovered from the complex ores of the Western states, the copper, lead, silver, and gold can also be extracted all of which are now almost valueless on account of the presence of the zinc.

Several metallurgical chemists, with whom I am acquainted, have spent time and money in experimenting on these lines with leaching processes for the treatment of complex ores, especially ore not suited to concentration schemes. Several of these processes have passed the experimental stage on small lots of a few pounds each, and the chemists are too poor themselves to erect a plant large enough to prove their statements on a commercial basis. When they present their schemes to individuals or corporations able to develop their ideas for them, the chemist generally asks too much and expects to keep control of the process through secrets or patents. He makes unreasonable demands. On the other hand, corporations are often represented by officials slow to act, even when they may think well of the process presented for their consideration; first, on account of the risk they take of injuring their own reputation in case the process should prove a failure after they have recommended it, and second, some of the officials themselves may have some schemes of their own and consider it their duty to work out a process for their company themselves. With these two conflicting elements, and the men with money naturally afraid of losing it, it is a difficult matter to get any new process developed so as to justify the installation of a plant large enough to treat such ore profitably, and if they did, those who control the process through patents or secret usage are not likely to let the public have the benefit of it. On the other hand, if the Government, through the Mining Bureau, had the process developed, and gave the inventor a reasonable royalty or purchase price, so as to release the process for use under certain conditions, including perhaps some small payment to the Government, then metallurgical advance would be facilitated.

The excellent research work now being carried on by Dorsey A. Lyon and others in the Bureau is not sufficient. It is necessary to select from and commercialize some of the processes suggested by this preliminary work, which should be continued by our Government.

I would suggest that the metallurgy of zinc be the first to be taken up and improved, on account of it being the commercial metal suffering the greatest waste at present, and because the recovery of the zinc from complex ores will save other valuable metals.

S. E. Bretherton.

San Francisco, July 17.

Stamp-Milling in Georgia

The Editor:

Sir—Your 'concentrate' in the issue of July 3, stating that "the first stamp-milling in the United States was done in Georgia," impels me to send you a photograph of a mortar which was in use in a stamp-mill at the Columbia gold mine, in McDuffie county, Georgia, in 1833. This mortar is now in the museum of the Hammond Laboratory, Sheffield Scientific School, Yale University.

MORTAR USED IN STAMP-MILL ON LITTLE RIVER, M'DUFFIE COUNTY, GEORGIA, IN 1833.

Gold was discovered at that place in 1829; and the working of the mine and mill was continued up to 1861, when the mill was dismantled by the Confederate government, which needed the boilers, engine, and iron equipment.

N. S. Keith.

Philadelphia, July 9.

The Talisman mine is one of the most important in New Zealand. During the year ended February 28, 1915, the mill treated 50,190 tons of ore by stamping and cyaniding, yielding 63,192 oz. gold and 116,534 oz. silver, valued at $1,224,000. Costs totaled $10.94 per ton. The operating profit was $777,000. Dividends amounted to $577,000.

Efficiency Engineering in the Copper Country

By P. B. McDONALD

The recent death of Frederick W. Taylor, the originator of efficiency engineering, or scientific management, evoked varying opinions as to whether or not the systems he advocated had succeeded. Not so much is heard of scientific management as was the case four or five years ago, when it first began to be applied to mining. Some mining men still retain their original enthusiasm for the system. Others see good in it, but also see limitations. Still others never cared for its principles. Thus Frank Richards, managing editor of *Compressed Air Magazine* speaks of 'Taylorism' as one of the fads that the American people seems to require to play with, and he quotes an English authority who styled it "a peculiarly hideous system of dehumanization." One of the mining regions where efficiency engineering, or 'Taylorism,' has been given a most thorough trial is the Lake Superior, more particularly in the copper country, where the Calumet & Hecla went into it on an extensive scale, being followed to a lesser degree by the other copper-mining companies, and also by some of the iron-mining companies on the ranges to the south.

By the Calumet & Hecla, as here mentioned, is meant not only the consolidated Calumet & Hecla mine proper, but also the several subsidiaries. It was in the Superior mine, near Houghton, under the superintendent, Ocha Potter, that most of the innovations and short-cut systems were tested before being applied to the larger mines at Calumet. Supt. Potter, a man of considerable experience and a graduate of the Michigan College of Mines, was a strong advocate of scientific management, as were likewise both John Knox, the general superintendent of the Calumet & Hecla, and James MacNaughton, the general manager, who took an active interest in all the different ways and means worked out by Potter and his assistants.

Efficiency in its every phase was gone into most thoroughly and minutely; drilling, blasting, 'mucking,' tramming, timbering, co-ordination of work, mechanical aids, improved rock-drills, care of old stopes, disposal of waste rock, tailing, etc. Observers with pencil, paper, and watches standardized all movements of the miners. New varieties of rock-drills of various weights, styles, and with different pressures of air, were tried and the advantages of each figured out. Suggestions were made to a company manufacturing rock-drills toward co-operation to produce a special drill, based upon information obtained from experiments in the copper mines, that would be exactly suited to the conditions and requirements of the tough amygdaloid rock of the copper country and to the abilities of the miners operating it. By carefully trying new methods at the Superior mine and proving them feasible before adopting them at Calumet, it was possible, when some of the old miners at the latter place said, "It can't be done," to bring Potter and one or two men from Superior and demonstrate that it could be done. Soon a regular staff of efficiency engineers was on hand in all the Calumet & Hecla mines, many of them college men who had been trained for their work by an apprenticeship at the Superior mine. The results attained were extraordinarily gratifying. In a comparatively few months the cost of driving had been reduced 60%; the cost of stoping had been decreased a smaller, but an appreciable, amount; timbering and general co-ordination of work had been materially improved. The new one-man drills proved great time-savers and cut costs immediately.

Driving, in its various phases of drilling a set of holes, blasting, and 'mucking,' offered a favorable opportunity for measuring what each man accomplished, and lent itself to standardization due to the self-contained and comparatively simple nature of the advance of a drift. The most noticeable gains in efficiency were achieved in driving. Stoping, with the difficulty in seeing and recording just what one miner had done and how much rock he had broken, was less amenable to scientific improvement, and it was found that stoping methods could not be accelerated to the extent possible with driving. But the most decided obstruction to the instant success of the plans of the efficiency engineers was the sullen opposition of a great mass of the miners. They did not like the new "pencil methods" of standardization, and particularly objected to working alone on the one-man drills. A few converts were made and won over to the cause of progress, but for the most part a stubborn resentment and general dislike against doing things by rote prevailed in the ranks of the thousands of Cornish, Finnish, Polish, and Austrian miners, who distrusted, mistrusted, and did not understand this comprehensive grafting of a standardized and detailed set of rules on what had hitherto been ordinary everyday mining.

The efficiency plans that the Calumet & Hecla gradually put into practice were so carefully entered into, so thoroughly worked out, and so systematically administered, that estimates of the amount of money they were going to save in operating ran into the hundreds of thousands of dollars per year. The cost of rock-drills, drill-repairing, and incidentals in general had mounted tremendously, but wonderful reductions in the cost per foot of driving and the cost per ton of rock stoped had been gained, as well as considerable savings in the amount of timber used and miscellaneous economies.

Just when scientific management had got into full swing, the disastrous labor troubles came, based, from the miner's standpoint, on antagonism to the one-man drill, to working alone, and to mistreatment by "petty bosses." Whether or not the strike of the copper miners

was a direct result of the efficiency engineering campaign is, of course, a matter of opinion. Possibly it would have come about anyway, regardless of efficiency systems. It is likely that the new methods of working had something to do with making it possible for agitators from the Western Federation of Miners to gain a foothold and a following in Michigan. In the end the copper mining companies won, but they lost a great deal of money from the long bitter struggle and expensive shut-down occasioned by the strike. It is not difficult to see that millions of dollars were lost both by operators and men in the weary months of fighting and bad feeling.

In so far as faster rock-drills and superior facilities for repairing them, better co-ordination of the different phases of underground work, and more accurate knowledge of practical mining, have resulted from efficiency engineering in the copper country, the system has been an undeniable success. As to any lasting or consistent speeding of the miners at their work, judges of the situation are not so sure. Averaging losses and gains in the labor element, an unprejudiced outsider could not be certain that the companies have benefited except in the mechanical line, particularly as regards rock-drills and their maintenance, and in better appreciation—on the part of the staff of officials—of the peculiar problems of underground mining. To get a correct valuation of the advantage or disadvantage of efficiency engineering, a long period of time should be considered, so that the effect on the labor situation could be gauged and weighed.

Other mining companies in the copper country followed the lead of the Calumet & Hecla, and worked out many economies and improvements in the standardization of underground methods. But like the Calumet & Hecla, they also lost heavily in the strike. On the iron ranges to the south and west, a few enthusiasts in scientific management developed, and the American mine at Diorite, the Munro Iron Mining Co. at Iron River, and even one or two of the Oliver mines on the Mesabi, conducted more or less complete experiments in observing, recording, and systematizing underground work. However, the iron operators were too busy with other matters, or were restrained by conservative Eastern managements from doing much more than experiment with the new ideas. Some creditable improvements were effected at several mines, such as better provision for getting dull drill-steel sharpened, timber-saving devices, faster rock-drills, economies in distribution and use of dynamite, etc., but scientific management, where known as such, was not persistent to any marked degree on the iron ranges. The individual iron mines merely continued to do common-sense operating, getting out the ore and shipping it, as cheaply and as handily as possible, while keeping all eyes open for wastes and leaks, as has always been done in the ore business of Lake Superior.

In the main, efficiency engineering in this region has accomplished a number of economies—mostly mechanical; in its effect on labor the advantage is doubtful, and undoubtedly the disastrous labor unrest was partly due to opposition by the miners to the attempt by efficiency enthusiasts at standardizing and speeding mining.

Silver Discovery in the Yukon

By D. SAUNDERS

The discovery claim was staked by H. W. McWhorter upon a creek that he subsequently named appropriately Galena. Galena creek is a tributary of the north fork of the McQuesten river; in fact, this part of the country might be correctly described as the headwaters of the McQuesten. Upon the first tier of benches from the level of the river there is a narrow canyon, about 70 ft. deep, offering all that could be desired in the way of help to the prospector, revealing, as it does, the formation splendidly. About 10 ft. above the level of the creek, between a hanging wall of quartzite and a footwall of mica schist (both walls being remarkably well defined) 4 in. of galena showed in the outcrop in a more or less decomposed condition. This, upon being assayed for silver, gave high returns. An adit was immediately commenced and, upon driving only a few feet, 12 in. of galena and considerable pyrargyrite was uncovered. Stoping operations were started, a trail was cut for 30 miles through gnarled and stunted firs, swamp, muskeg, and mosquitoes to Mayo Landing and as soon as the snow began to melt 59 tons of ore was piled at the landing to await spring and the 'break-up.' After being freighted down the Stewart river, the ore was carried up the Yukon to Whitehorse, over the White Pass by railroad, and down the Pacific coast to Vancouver, where it was again trans-shipped. The ore eventually landed at the smelter at Trail, British Columbia, somewhat travel-stained and worn but still able to fetch the welcome returns of $269 per ton. [Some of it came to the Selby smelter, San Francisco].

A shaft was then sunk upon the vein to a depth of 100 ft. and a cross-cut driven for 60 ft. To the 100-ft. level the vein maintains a fairly uniform width of 24 in. from wall to wall, dipping at an angle of 35°, the general strike being north-east.

At this depth a rich ore-shoot about 30 feet wide was followed down for another 60 ft., the orebody rapidly becoming wider and the dip a little steeper, the galena averaging 40 in. in width, with 12 in. of vein-filling carrying pyrargyrite in abundance. Argentite and stephanite in less proportions are also observed. Already 1380 tons of ore has been extracted (by single-jack work), sacked, and shipped to the smelter.

Development work is rapidly proceeding in an endeavor to get enough ore in reserve to warrant the erection of a reduction plant, the ore being amenable to concentration either by oil-flotation or water. The cost of development in a new camp is always high, but the cost of transportation from a remote place like the watershed of the McQuesten to the nearest lead smelter can only be described as terrific.

Some systematic and thoughtful prospecting along the strike of the vein has been done on both sides of the discovery claim but up to the time of writing nothing worthy of note outside of the one rich small shoot—about 30 ft. wide—now being worked, has been disclosed.

Flotation in a Mexican Mill

By A SPECIAL CORRESPONDENT

Present Concentrating Methods. The mill receives 200 tons per day of crude mine ore. After being crushed to 2-inch size, this ore is passed over a picking-belt, where one ton of high-grade ore and four tons of waste are removed each day. The remaining 195 tons of second-class ore is crushed in stamp-batteries, to pass a 4-mesh screen. Lime-water, in the proportion of 7 of water to 1 of ore, is added in the battery. The pulp from these is classified roughly, the coarse sand being ground in a Hardinge mill to pass a 20-mesh screen. The pulp is again classified roughly into four sizes of sand and one size of slime. The sand is concentrated on Wilfley tables and the slime (after being settled to 7:1 in cone-bottom tanks) is concentrated on Deister tables.

The slime-tailing, from the Deister tables, is re-concentrated on vanners. The tailing from the vanners settles to 3½ tons of water per ton of slime; the water being further reduced to ¾:1 in a vacuum-filter. The filter-cake is washed with weak barren solution before being sent to the cyanide plant.

The sand-tailing from the Wilfley tables of the stamp-mill is classified carefully in mechanical classifiers; the slime under-size joins the slime-tailing from the re-concentrating vanners, and the sand (after the addition of cyanide solution) enters the tube-mill circuit, where it is joined by 50 tons per day of dump-tailing. All tube-milling is done in cyanide solution. After passing through the tube-mills, the combined current and dump sands are re-concentrated on Wilfley tables. The tailing from these tables is classified, the coarse sand re-entering the tube-mill circuit and the slimed sand being thickened in three 24-ft. Dorr vats before entering the cyanide plant.

Metallurgical Results of Present Methods

	Gold, oz.	Silver, oz.	Copper, %	Lead, %
The feed to the stamp-mill assays	0.1	35.4	0.25	0.7
The concentrate assays	2.0	570.0	2.0	10.0
The tailing, after concentration, assays	0.03	18.0	0.15	0.4

The recovery therefore is: gold, 65; silver, 48; copper, 35; and lead, 45%.

Necessity of Better Concentration. The above data show that a little more than half the gold is being recovered in concentration, and that the recovery on silver, lead, and copper is less than half the contents in the original ore.

Tests indicate that more than 90% of the metal in the original ore occurs in the form of sulphides. Hence half of the metallic sulphides of the original ore enters the cyanide plant. This is undesirable for the following reasons:

1. The extraction of silver from sulphide metals is poor in the cyanide plant; the concentrate produced from panning current residue assays between 50 and 100 oz. silver per ton, and the tailing from panning invariably assays below 2 oz., even when the residue assays as high as 5 oz.; showing that the poor extraction is due to undissolved silver in the sulphides.

2. The presence of metallic sulphides increases the cyanide consumption. The chemical consumption of cyanide is reduced from 4 to 1 lb. per ton when the metallic sulphides are removed from the heading to the cyanide plant. The present excessive cyanide consumption is due almost entirely to the solution of copper from the ore.

3. The presence of copper and zinc sulphides in the cyanide pulp fouls the solution, thus decreasing the extraction from the rest of the ore.

The possibility of improving results by better concentration of the ore has long been recognized. For this reason, arrangements were made for re-concentrating. Both arrangements have effected a reduction of assay-value in the final residue and a corresponding increase of profit.

Methods for Improving Present Concentration. Lately, extensive tests have been made to determine the possibility of still closer concentration. Careful panning reduces the average feed to the cyanide plant from 18 oz. silver to 10 oz. per ton.

Canvas tables give slightly poorer results. A full-sized canvas table, treating tailing from the Deister tables (assaying 20 oz. per ton) produced 15 oz. tailing—an extraction of 25%. Further tests along this line were discontinued on account of securing much better results from laboratory flotation tests.

Laboratory Flotation Tests. All flotation tests, made in the laboratory, were run in separatory funnels. The general procedure in the tests was to mix 100 grams of *minus* 200-mesh ore with water in proportion of four of water to one of ore. Suitable amounts of oil were then added and the mixture shaken violently. After allowing the pulp to settle for a few moments, the bottom cock of the funnel was opened and the tailing run into a second separatory funnel for another flotation treatment; the cock being closed before the froth began to run out. This process was repeated, on the tailing, from five to seven times. Several hundred tests have been run, all possible variations of conditions being tried. The results of the tests led to the following conclusions:

1. All ores from the mine may be treated by flotation. Semi-oxidized ore from one level yields a tailing assaying 10 oz. silver per ton, while the oxidized ore from another level gives a tailing containing only 2 oz. per ton. The tailing from average ore, when conditions for flotation are right, is 4.5 oz. silver per ton.

2. The grade of tailing appears to be independent of

whether the original ore is treated by flotation, or whether wet concentration precedes flotation.

3. The alkalinity during flotation must be between 0.01 and 0.05 lb. per ton of solution. The best results are secured when the alkalinity is 0.025 lb. When the alkalinity is too low, the extraction is poor although the concentrate is clean. When the alkalinity is too high, both the extraction and grade of concentrate are poor. When the alkalinity is right (0.025 lb.) both the extraction and grade of concentrate are best. The maintenance of proper alkalinity will require the most care of anything in the plant; although it will not be more difficult than the maintenance of proper cyanide strength in the cyanide plant.

4. The dilution may range between $3\frac{1}{2}:1$ and $7:1$; with the best results, on average ore, between $4:1$ and $6:1$. When the pulp is sandy a low dilution is best: pure sand, ground to 200-mesh, requires a dilution of $1:1$. Average slime, like the Deister feed, on the other hand, requires a dilution of $8:1$. Good extraction may be secured on either sand or slime, provided approximately the proper dilutions are secured in each case. Proper dilutions will be easy to maintain in the plant, for the range for the best work is comparatively large; and when either an excess of sand or an excess of slime occurs in the ore, the proper dilution will automatically adjust itself; for the sand of itself will settle to a thick pulp, while the slime will not settle well, but will remain thin.

5. The temperature is not a matter of vital interest. The extraction is slightly better and the grade of concentrate considerably higher when the temperature is over 100° F., but good results have been secured with the temperature as low as 40° F. It will not be necessary to arrange for heating the pulp, especially at the start.

6. Fine grinding is necessary for good results in flotation. When the mill-heading was crushed to 60-mesh, the tailing from flotation assayed 0.08 oz. gold, and 11 oz. silver; when the same ore was crushed to 100-mesh, the tailing assayed 0.04 oz. gold and 5 oz. silver; and when the crushing was carried to 200-mesh, the tailing assayed 0.02 oz. gold and 3.75 oz. silver.

[The question of the kind of crushing mechanism best adapted to preparing ore for flotation is vital; at present the tube-mill, ball-mill, and disc-crusher hold the field.—Editor.]

MEXICAN MEANS OF TRANSPORT.

7. The best flotation agents, so far tested, are pine-oils. Low-grade pine-oil gave as good results as the higher-grade varieties. S. S. pine-oil, of the General Naval Stores Co. (cost 26c. per gal., f.o.b. factory) has given exceptionally good results. For the best work in flotation it is necessary to have this oil present to the extent of 0.6 lb. per ton of ore. In actual plant-practice, where the water is returned again and again to the top of the mill, the consumption of oil will probably be about $\frac{1}{4}$ lb. per ton of ore. This oil will cost, delivered, 8c. per pound.

Pine-tar oil is much cheaper. It gives good extraction, but the grade of concentrate is low. Cresylic acid, when used with pine-oils, increases the extraction about $\frac{1}{4}$ oz. silver per ton. This hardly pays for its use.

8. In the laboratory tests the grade of concentrate was

low, averaging 200 oz. silver per ton. This concentrate could be raised to 1100 oz. by re-treating the concentrate by flotation.

9. Cyanide tests, run on tailing from the flotation tests, produced residues assaying less than 1 oz. silver per ton, with a cyanide consumption of less than 1 lb. per ton.

10. The dump-tailing cannot be easily treated by flotation. When the methods of flotation that are applicable to mine ore are applied to the dump-tailing, the results are *nil*. Furthermore, when the water that has been in contact with the dump-tailing is used for diluting mine-ore, the mine-ore cannot be treated advantageously by flotation. Experiments show that both these effects are due to the presenee of soluble sulphates (chiefly those of magnesium and calcium) in the dump-tailing. The injurious effect of magnesium sulphate can be overcome largely by an excess of oil. No method of overcoming the injurious effects of calcium sulphate has yet been discovered in the tests.

When the dump-tailing is washed in fresh water half a dozen times, before being treated by flotation, the results of flotation are as satisfactory as is the case with mine-ore. However, a plant for washing the dump-tailing would be more expensive than the small tonnage of this material warrants, and the operation of such a plant would neeessitate the waste of more water than is available. Some other method of rendering the dump-tailing susceptible to flotation may be devised; but the small tonnage does not warrant any extended investigation. The best thing to do, especially at the start, is to send the dump-tailing direct to the cyanide plant (after concentrating the ground sand on Wilfleys) as at present.

11. As a result of the laboratory experiment, it was decided that full-sized tests should be conducted in the plant on run-of-mine ore.

Plant Tests. For this purpose, there were set aside for the flotation circuit, one battery of five stamps, two Wilfley tables, one classifier, one tube-mill, one 24-ft. settler, and one pump for returning the water from the settling-tank to the head of the mill.

A flotation-cell of the pneumatic type was first tried. When treating 20-oz. heading this machine produced a 290-oz. concentrate and a 15.3-oz. tailing. This was far from satisfactory.

Another machine consisted of a series of mechanical-agitation chambers, alternating with a series of settling-chambers. From the start, this machine has given excellent results. In spite of many mechanical difficulties, and trouble with inexperieneed operators, the tailing from the plant has averaged but little above 5 oz. silver per ton, and the concentrate has averaged above 600 oz., without re-concentration.

The chief weaknesses of mechanical agitation, as ascertained in this mill, are:

1. The complex system of shafts and counter-shaft, with the corresponding drives, bearings, etc.

2. The difficulty of adjustment; any slight change in feed necessitating a change in the valves of each chamber.

3. The difficulty of the passages between chambers becoming clogged.

Submerged Agitation. It has been attempted to evolve a flotation machine to overcome these weaknesses, and at the same time give results as good as the mechanical agitation plant. A small machine (capacity 3 tons per day) has been constructed, and this, after many alterations, has yielded a 3.7-oz. tailing and a 680-oz. concentrate, when treating 10-oz. feed. This machine employs a somewhat unique principle of flotation—that of submerged agitation—the mixture of pulp, oil, and air being violently agitated in a partly closed chamber, under the hydrostatic pressure of several feet of pulp in the settling-chambers above.

In construction, this machine is simpler than the machine using mechanical agitation. It consists essentially of a V-shaped box or trough, divided into compartments by a series of vertical partitions. At the bottom of each partition is an agitation-chamber. Agitation is supplied by a paddle-wheel in each chamber. All the paddle-wheels are mounted upon a single horizontal shafting, which passes the entire length of the trough, leaving the end partitions through stuffing-boxes. The pulp enters each agitation-chamber through an opening around the shafting, and leaves the agitation-chamber through an adjustable aperture, at a slight distance from the shafting. The agitator thus acts slightly as a centrifugal pump, overcoming the friction loss in the passage from one compartment to another, and keeping the height of the pulp the same in all the settling-chambers. The adjustment of the aperture is arranged to increase or decrease the centrifugal force. This adjustment occasions much less difficulty than is experienced in mechanical agitation, where the flow from one compartment to another is merely throttled.

Also, in the new plant there are no pipes to become clogged, the passage of pulp from one cell to another being along a rapidly revolving shafting, which keeps all material in suspension. The concentrate overflows from both edges of the trough, thus being removed more promptly than in a plant using mechanical agitation.

Further tests with the small machine are being made, and a larger machine (eapacity 40 tons per day) is being constructed, for thoroughly testing the principles involved. The 40-ton machine will be constructed with the idea of using it for re-concentration of the concentrate, should a full-sized flotation plant be installed.

Simple Mechanical Agitation. The machine has now been operating intermittently for a month. During that month it ran six days continuously, treating 25 tons of 29-oz. pulp and producing 6.4-oz tailing and 600-oz. concentrate. During the first five days of the following month, careful tests were run to compare flotation results with those from current concentrating praetice. The following tables give the summary of results from these tests.

Mill-Tests. Flotation *v.* Present Concentration Practice. Flotation plant takes 25 tons per day of mill heading after being crushed to 20-mesh by stamps, concentrated on Wilfleys, and passed through a tube-mill.

Bullion, 24.88 oz. gross; gold, 0.0427 oz.; silver, 16.59 oz. per ton.

*Throughout this article values are given in U. S. Currency.

Less haulage, freight, and treatment, at $19.67 per ton	$0.80	
Less taxes, commission, and expense, 7.44%	0.86	1.66
Bankable funds per ton of ore		$9.82
Bullion from current tailing, 24.88 oz. gross:		
Gold, 0.0427 oz. at $20.67	$0.88	
Silver, 16.59 oz. at 50c	8.29	
	$9.17	
Less haulage and treatment, at 1.08c. per oz.	$0.26	
Less express, taxes, etc., 7.8%	0.72	0.98
Bankable funds per ton of ore		$8.19

COSTS. Labor and repair costs will remain about the same as now. Two high-class operators in the present re-treatment plant will be replaced by three cheap operators in the flotation plant.

Power consumption will be increased about 40 hp. This will cost 5c. per ton.

Oil consumption will be about $\frac{1}{4}$ lb. per ton of ore. $\frac{1}{4}$ lb. @ 8c. = 2c. per ton.

The total increase in the cost of concentration will therefore be about 7c. per ton.

The present cyanide consumption per ton of ore is 6 lb., of which 2 lb. is mechanically lost. Small laboratory tests show that the chemical consumption of cyanide when flotation-tailing is treated, is only 1 lb. per ton of ore. This is 3 lb. less than the consumption when current tailing is treated. If this result is sustained in actual plant-practice, the saving in cyanide alone will amount to 3 × 19c. = 57c. per ton of ore.

The present cost of precipitation and melting is 2.56c. per fine ounce.

In present practice 16.6 fine ounces are produced per ton of ore. When flotation tailing is treated, only 3.7 oz. are produced per ton of ore. This means an excess of 12.9 oz. produced in present practice: 129 × 2.56c. = 33c. per ton of ore.

Probably this amount would be reduced to 28c. on

account of certain fixed labor and pumping charges, which will not be materially reduced if the flotation plant is installed.

FINANCIAL STATEMENT

Flotation *v.* Present Practice, per ton of original ore.

	Present practice.	Flotation.
Bankable funds; marketing concentrate....	$9.82	$17.14
Bankable funds; marketing bullion	8.19	1.73
Increased cost of concentration.....	0.07	....
Decreased cost of cyanide.....	...	0.57
Decreased cost of melting and precipitation.	...	0.28
	$18.08	$19.72

Increased profit per ton from flotation, 200 tons per day at $1.64 = $328 increased profit per day or $9840 increased profit per month.

The above is calculated on the basis of results from a single mill-test of 5 days' duration. During this interval the heading to the mill and the residues were excessively high; indicating a greater advantage in favor of the flotation plant than is actually warranted.

The estimate of probable profit may be revised roughly by using the metallurgical results of the past two months for the basis of calculations. During two months the heading to the cyanide plant has averaged 17.8 oz. silver, and the residue has averaged 2.75 oz. per ton. The residue from cyanide-flotation tailing would assay 1 oz. per ton. This indicates an increased extraction of 1.75 oz. silver per ton of ore. 1.75 oz. at 41c. = 72c. increased profit per ton.

The indicated decrease in cyanide consumption (as determined solely in the laboratory) is 3 lb. per ton of ore. Reducing this to 2½ lb., to be on the safe side, the decreased cost of cyanide would be 2½ × 19c. = 47c. per ton of ore.

The decreased cost of precipitation and melting may be figured as follows: Cost of precipitation and melting, per fine ounce, has been 2.4c. The decreased production of bullion, due to flotation, would be 11 oz. per ton of ore. 11 oz. at 2.4c. = 26.4c. When fixed charges are considered, this should be reduced to 20c. per ton.

When the profit from marketing an increased amount of lead and copper is balanced against the increased loss occasioned by marketing the silver and gold as concentrate instead of bullion, there is a deficit of 17c. per ton of ore.

The matter may be summarized as follows:

	Per ton.
Increased extraction	$0.72
Decreased cyanide consumption	0.47
Decreased cost of precipitation and melting.....	0.20
	$1.39
Increased cost of marketing	0.17
Profits per ton of ore	$1.22

The average tonnage of mine-ore for the past two months has been 5761 tons. Hence the indicated increase in monthly profit would be 5761 × $1.22 = $7028.42.

INSTALLATION OF FLOTATION PLANT. Should a flotation plant be installed, operations in the stamp-mill will continue as at present; though it may be deemed advisable, after the flotation plant is running smoothly, to eliminate concentration in the stamp-mill, and depend upon the flotation plant for all concentration.

Re-concentration of current tailing on vanners and Wilfleys will be discontinued from the start.

The dump-tailing will be treated as at present, with the exception that this material will enter the plant only in the day-time. One tube-mill, one classifier, one elevator, and the re-concentrating Wilfley tables will be kept separate from this circuit, which will be in cyanide solution. All lime for the cyanide plant will enter this circuit. One of the 24-ft. tanks and one of the pumps must be reserved for the dump-tailing circuit.

All the tube-milling of current sand tailing will be done in mill-water, instead of cyanide solution.

The ground sand, together with the current slime, will be settled in two of the 24-ft. thickening-tanks, and will then enter the flotation plant. From the flotation plant, the tailing will flow to the two 33-ft. thickening-tanks. The thickened pulp from these tanks will be de-watered and washed in the vacuum-filter before entering the cyanide plant.

All lime for the mill-circuit will be added as an emulsion to the flotation-tailing launder, where it will be under direct control of the flotation-operator. The water in the 23-ft. thickening-tanks will contain about 0.4 lb. dissolved lime per ton. This is ample for good settling. The overflow from these tanks will be reduced, by consumption, to about 0.1 lb. per ton. This is sufficient for fair settling in the cone-bottom tanks of the stamp-mill. By the time the pulp reaches the 24-ft. thickening-tanks the lime will be reduced to 0.03 lb. per ton. This low lime will be extremely detrimental to good settling in these tanks.

INSTALLATION REQUIRED. The matter of supplying proper settling and de-watering facilities will be the most serious and most expensive part of the installation.

The two 24-ft. thickening-tanks, to be used in the flotation-circuit, must be triple-decked. It will also probably be found necessary to double-deck the 32-ft. steel thickening-tank. The work on settling-tanks will cost about $6000.

By increasing the settling capacity, the pulp will probably be settled to a sufficient thickness that the vacuum-filter will be able to handle the combined sand-slime feed.

It may be found necessary, however, to add another unit to this plant. This will cost $2000.

The flotation plant will consist of two units (each of which will be able to treat the total tonnage of current tailing) and one smaller clean-up machine. The whole plant will cost about $3000. A filter-press for handling the concentrate will cost $2000. Tanks, air-lifts, launders, and buildings will cost $2000. Thus the whole installation will cost $15,000, or $20,000 at the most. The addition of the flotation plant, for treating current tailing, will increase the profit about $7000 per month. Practically all ore from the mine may be treated by flotation.

PLAZA OF POTOSI.

THE MOUNTAIN OF POTOSI.

The Potosi Tin-Mining District, Bolivia

By FRANCIS CHURCH LINCOLN*

History. The Potosi tin-mining district is near the city of Potosi in the south-central part of Bolivia, South America. Besides the mines in the immediate vicinity of the city, it may be considered to include the Huari-Huari mines 15 miles northeast and the Porco mines 30 miles southwest. The Potosi mines are much older than those of the Milluni and Quimsa Cruz districts, both of which have been described in previous articles†, those at Porco having been discovered long before Columbus landed in America, while the Bolivian Indians were still under the rule of the Incas.

Maita Capajh, fourth of the Incas, whose reign began in 1171, extended the boundaries of the Inca empire from Cuzco, now in Peru, as far as what is at present the city of La Paz in Bolivia. During this extension, the rich silver mines of Porco were discovered and were afterward worked by Maita Capajh and his successors upon a large scale. The name Potosi is said to have originated with a later Inca, Huaina Capajh, who camped near the beautiful peak in 1462. So impressed was he with the grandeur of the mountain, that he thought it must contain silver and sent some of his retainers there to prospect for the precious metal. The prospecting party was overtaken by one of the violent thunderstorms prevalent in that region, and becoming frightened by a terrific peal of thunder, ran back to the Inca with cries of "*Potojsi*!", which is the Quichua Indian for "It made a loud noise!" The prospectors also declared that in the calm succeeding the report they had heard a voice saying, "Touch not the silver of this mountain, it is for other owners!" Some doubt is cast upon the veracity of this ingenuous tale by the existence of another Quichua word, *potojchi*, which means 'fountain of silver,' and whose applicability is apparent without the aid of a picturesque story.

The silver in Potosi mountain was discovered at the beginning of the Spanish colonial period. According to the historian, Marco Jimenez de la Espada, four Spaniards who were seeking argentiferous galena in the neighborhood in 1544, sent an Indian named Gualpa with a companion to the summit of the peak to collect any valuable offerings that might have been made in the huaca, or sacred spot, situated there. Nothing of great value was found, but Gualpa loaded his companion with part of the offerings remaining to gather the rest himself. A violent windstorm then descended from the top of the mountain, knocking Gualpa insensible. When he recovered and started to rise, he found in his hand a rich lump of silver ore. Another historian says the discovery was made by an Indian chasing a stray sheep, and there are several other yarns in circulation as to how the famous mines were discovered, but whatever may be the true one, it is at least certain that in 1545 the city of La Plata, later known as the Villa Rica Imperial de Potosi, was founded by 75 Spaniards and the exploitation of the mines was begun. Reports as to the annual and total productions of the silver peak of Potosi vary greatly, but according to Wendt‡, who has made a careful study of the subject, there is little doubt that the aggregate product has exceeded 1,000,000,000 ounces. Potosi has therefore been the largest silver producer in the world.

The Huari-Huari silver mines were also discovered by the Spaniards, who operated them upon a comparatively small scale. Huari-huari means "many vicuñas," the vicuña being a wild Andean animal closely related to the domestic llama.

All the mines of the Potosi district therefore have been

*Director Mackay School of Mines, Reno, Nevada.

†Mining and Scientific Press, March 27 and May 8, 1915.

‡Trans. A. I. M. E. Vol. XIX, p. 74, (1891).

worked for silver in the early days. Within recent years, however, these mines have become important tin producers, while their production of silver has become almost negligible.

Geography. Potosi is situated on a branch of the Antofagasta & Bolivia Railway, which leaves the main line at Rio Mulato, 106 miles distant, and crosses a pass 15,770 ft. in elevation, to reach the city, which is itself at an elevation of 3560 ft. above sea-level. The population is about 35,000. The peak on which the mines are situated rises to a height of 2000 ft. above the city, forming a nearly perfect cone, and as the surface of the hill is almost completely covered by multicolored mine-dumps, it presents a strikingly beautiful appearance.

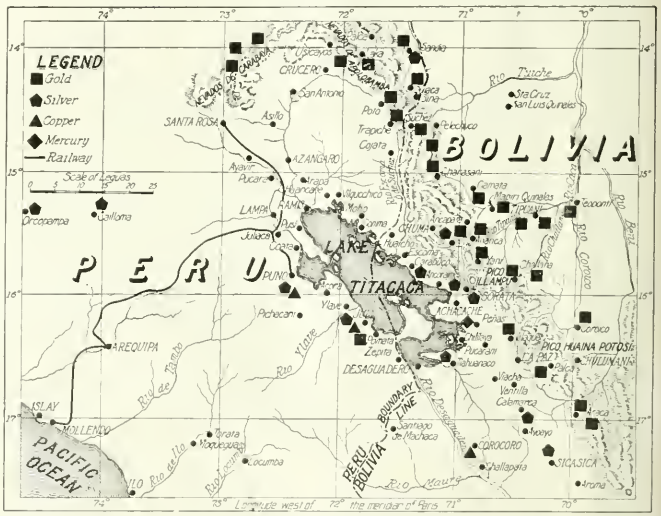
Porco is 2 miles from the railroad at Agua Castilla, and about 30 miles from Potosi. The mines are in the hills near the town and are connected with the mill, which is near the station of Agua Castilla, by an aerial tramway. The town is a small one, inhabited only by Quichua Indians.

The town of Huari-Huari is also a small one, only inhabited by Indians. It is 18 miles from the terminus of the railway at Potosi, and at an elevation of 13,100 ft. From Potosi, the road to Sucre (the nominal capital of Bolivia) is followed for 12 miles to the baths of Don Diego, whence a branch road 6 miles long runs to Huari-Huari. The mines are situated in the hills above the town.

Geology. Potosi peak is formed of rhyolite intrusive through Jurassic shale and sandstone, as well as Tertiary sandstone. The veins form a linked system that cuts all the country-rock indiscriminately. Tin and silver occur together in these veins. The tin is usually in the form of light-colored cassiterite (tin oxide), rarely in that of stannite (sulphide of tin, copper, and iron). The silver mined from near the surface was mainly in the form of chloride and native silver, but in depth most of it is contained in argentiferous tetrahedrite. Quartz and iron oxides are the principal gangue-minerals of the oxidized ore, while pyrite, a little chalcopyrite, and occasionally sphalerite and galena occur in depth.

At Porco, the geological conditions are similar to those at Potosi, save that no Tertiary sediments have as yet been discovered and that silver frequently occurs as ruby silver (proustite). At Huari-Huari, however, the ore deposits are of a somewhat different character. The town occupies a valley with Mesozoic sediments on one side and Paleozoic sediments on the other. Tin-silver veins occur in the Mesozoic shale, no igneous rock having been cut in the mines. The tin is in the form of cassiterite, while the silver occurs as pyrargyrite and as argentiferous jamesonite, with galena. Pyrite, hematite, and sphalerite also occur in the veins.

Mining. The mines of the peak feel the ill effects of mining regulations dating from early Spanish times that are not in effect in the newer tin-mining districts of Bolivia. According to these old laws, mining property is not held by surface claims as under the new laws, but by *boca minas*, or mine-openings, each of which pays a tax of 4 bolivianos (about $1.60) per year. There are some 5000 mine-openings, mostly in the form of adits in the mountain. These workings may be continued indefinitely as long as they do not run into those starting from other mine openings. As far as surface boundaries are concerned, it is evident that the mine-opening claims may overlap one another, and that the quantity of ground controlled by one mine opening is dependent not only upon its position, but also upon the activities in neighboring mine-openings. It will be seen readily that the opportunities for litigation far exceed those made possible by our own apex law; our own system is not, therefore, the worst in the world as some of those who have experienced its drawbacks are inclined to believe.



MAP SHOWING POSITION OF POTOSI.

The miners at Potosi receive from 2 to 5 bolivianos per day, (from $0.80 to $2), while at Huari-Huari the scale of wages is lower, being from 1 to 2 bolivianos (40 to 80 cents). Mining is conducted in a most casual and desultory fashion, the principal operators in Potosi being the French firms of Louis Soux and Bebin Frères. Regular mining operations have recently been begun at Porco by the Porco Tin Mines, Ltd., a subsidiary company of the powerful firm of Aramayo, Francke Mines, Ltd., which is operating many tin, copper, and bismuth mines in Bolivia.

Milling. A list of the principal mills operating in the Potosi district in 1914 is given herewith, together with their approximate monthly productions of 60% tin concentrate.

TOWN OF PORCO.

QUICHUA INDIANS.

Mill and owner.	Concentrate, Tons.
Velarde, Louis Soux	140
Huayra, Bebin Frères	80
Socavon Royal, Anglo-Bolivian Mining Syndicate	40
Cucho, Arturo Casada	30
Colavi, Alfredo Metting	20
Huari-Huari, Cia. Minera y Agricola Huari-Huari de Potosí, A. Delgado, manager	20
Re-working tailing, Matias Mendieta	27.5
Re-working tailing, Mendoza y Cia	15

None of these are modern mills, and their operations are in every instance both crude and inefficient. Jigs, Wilfley tables, and convex or concave buddles make up the usual equipment. A general impression seems to be prevalent that the Wilfley table should discharge all its products over the head end, and to insure this some of the mills even go so far as to attach boards to the sides of the Wilfleys to prevent their discharging in the ordinary manner! It is therefore not surprising to learn that in one mill the Wilfley tailing is re-treated no less than 8 times to get the content down to 1% tin!

A brief description of the milling process as conducted in the largest mill may prove of interest. The ores are obtained from various mines and dumps; they range from rich ores containing 15% tin and 8 marcos per cajon of silver (about 24 ounces per ton), to poor dumps containing only 1% tin. The silver-bearing ore is first treated by the hyposulphite lixiviation process to remove the silver, and concentrated afterward for the tin. Water-power is used, supplemented in the dry season by power obtained from a 70-hp. oil-engine burning Peruvian oil, which costs about 35 cents per gallon delivered at the mill. The tin-silver ores are roasted in small hand-rabbled reverberatory furnaces, first raw and then with salt. The fuels employed are *yareta*, a resinous plant, and *taquia*, llama dung, the cost being about $8 and $5 per ton, respectively. After being subjected to the chloridizing roast, the ore is leached with hyposulphite solution in sixteen 14-ton vats, one of which is emptied daily. Next the silver is precipitated with calcium sulphide, giving a product containing from 40 to 50% silver and 1 oz. gold per ton. The tailing from the lixiviation, together with ores low in silver, is concentrated for the tin content by the methods described above. The high cost of power accentuates the cost of inefficient methods.

The two mills mentioned last in the list, as re-working tailing, are situated below the city of Potosi and have no mines of their own. They are engaged solely in concentrating the tailing that escapes from the mills up-stream, and their success plainly indicates the heavy losses from which the regular mills are suffering.

Smelting. Twenty years ago there are said to have been no less than 9 tin-smelting furnaces in continuous operation at Potosi. This number was reduced as it became necessary to go farther and farther for fuel. Finally, with the advent of the railroad in 1912, tin-smelting practically ceased. This was because the railroad in its endeavor to secure back-haul to the coast made such favorable rates on the concentrates that it became cheaper to ship than to smelt. At the time of my visit, in 1914, the furnace of Bebin Frères had not been run for over a year, while that of Louis Soux had been running intermittently on old slag that could not be concentrated. These furnaces are small water-jacketed blast-furnaces.

The charge formerly used by Bebin Frères consisted of

100 lb. tin ore or concentrate
60 lb. charcoal
5 to 10% limestone

The fine was briquetted with 5% of lime before being charged. Coke was occasionally substituted for charcoal, but it is said to have made a fire too hot for the furnace. The limestone came from a distance of 12 miles, and the charcoal from 24 to 30 miles. The costs of fuel at Potosi are as follows:

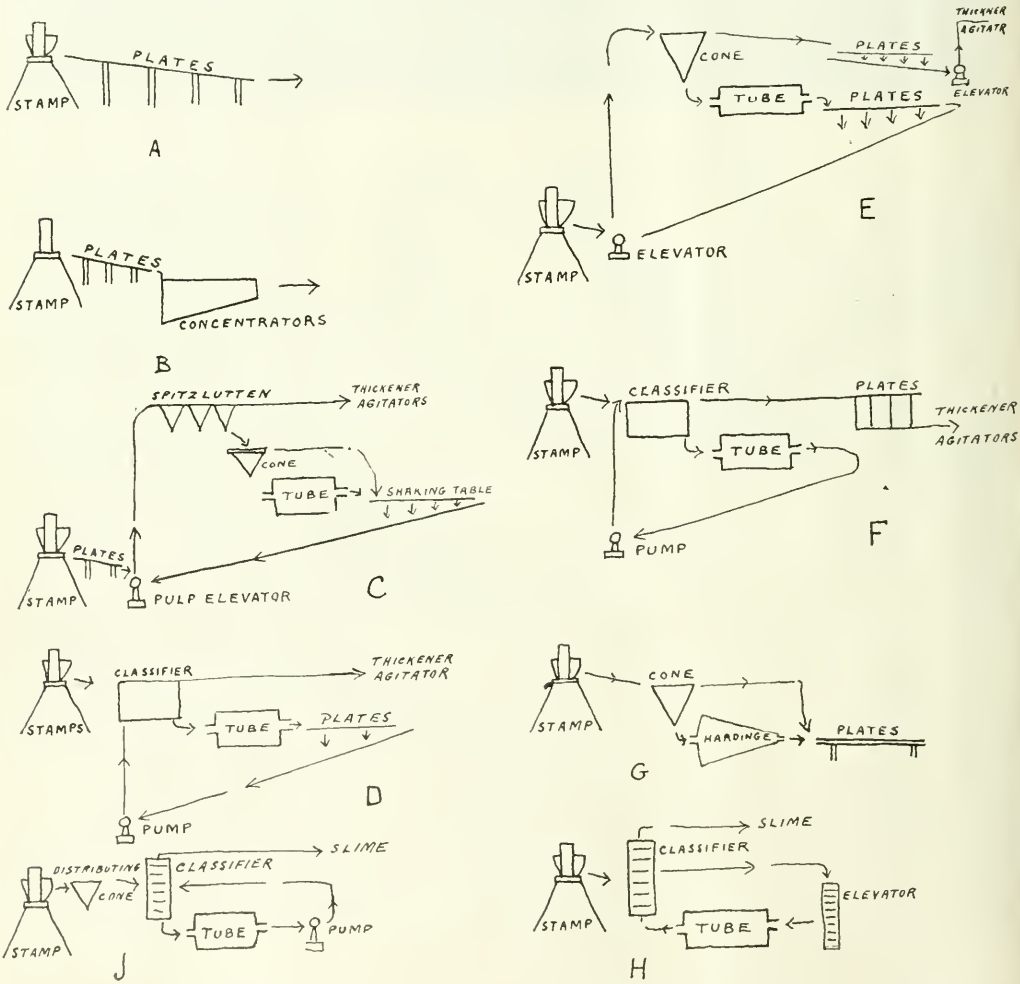
	Per ton.
Queuña charcoal	$36
Churqui charcoal	40
Cardiff coal	42
Coke	60

Louis Soux was smelting old slag containing from 4 to 7% tin, briquetting the fine with 10% lime, and claimed to be getting bars running from 94 to 96% tin and a slag containing only ½% tin.

The Position of the Tube-Mill

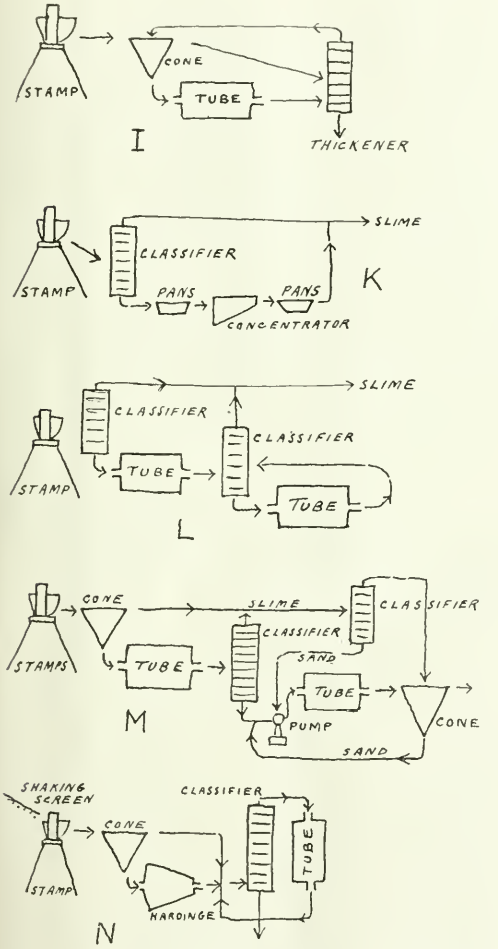
By ALGERNON DEL MAR

The millman must recognize the fact that the tube-mill has come to stay; whether we amalgamate after stamping or not, we must fix the position of the tube-mill in respect to the stamps and classifiers so that the whole process of extraction is benefited. The most important modification noticed in stamp-milling in consequence of re-grinding in tube-mills is that the point in the process at which the gold is extracted by amalgamation has changed. In times past the gold was always amalgamated in the mortar of the stamp-mill and the plates were immediately in front of the battery. We then saw the plates go to a separate building, still taking the pulp from the stamps; then with the advent of the tube-mill in the metallurgical treatment of gold ores the plates were placed in the tube-mill circuit and abandoned in front of the battery; then amalgamation was tried in the tube-mill and classifier circuits; then we find amalgamation taking place in the tube-mill and not in the stamp-mortar, and then amalgamation was confined to the classifier circuit. Nearly the whole cycle of possible combinations has been tried, and, like many other problems in gold extraction, we must study each



particular ore as a distinct problem. The simplicity of amalgamating after classifying and before thickening looks promising, but unfortunately we have no published data comparing this method with battery-amalgamation.

The following diagrams show the flow-sheet for a free-milling ore without the tube-mill; then the various positions of the tube-mill in respect to stamps with amalgamation as a feature; then the position of the tube-mill in the all-cyanide process.



A represents an absolutely free-milling process as at the Yellow Aster mill, California, where the whole process of extraction is in the battery and on plates.

B shows amalgamating in the stamp-battery, on plates, saving the concentrate, as in the usual California mills.

C. The plates are in front of the battery and likewise after the tube-mill.

D has tube-mill plates, but none in front of the stamps.

E has plates after the tube-mill and classifier.

F has plates after the classifier.

G shows amalgamation inside tube-mill, and in the tube-mill and classifier circuits.

We then have various modifications of the all-sliming process, using cyanide as the sole means of extraction.

H indicates the tube-mill taking sand from a Dorr classifier and returning ground pulp to the same, the elimination of slime being from the classifier.

I. The tube-mill takes the underflow from the cone, the overflow of the classifier, the tube-mill product going to a classifier, and the sand to a cone.

J. A distributing cone feeds a classifier, the elimination of slime from the circuit being from the classifier.

K. The stamps feed direct to a classifier, the oversize going to pans and concentrators. The slime is eliminated at the classifier, to which is added the product from the last pan, which can hardly be called all-sliming, but could be converted into such by returning the pan-overflow to the classifier.

L. Two tube-mills and two classifiers working in a closed circuit, the slime being separated from both classifiers.

M. Cone classifiers and tube-mills in a closed circuit, the slime being separated in the last cone.

N. Shaking screen before stamp, oversize to battery, undersize joins battery-discharge, both going to cone, undersize from cone to classifier, oversize of cone to Hardinge mill, cylindrical tube-mill in closed circuit classifier, slime eliminated from classifier. This is probably the most complete stage-reduction, as each machine is doing the work for which it is best fitted.

These diagrams represent the procedure in the several plants indicated, and while it does not exhaust the possible combinations, it is sufficiently extensive to show the great variety of processes of ore reduction now used for gold extraction by amalgamation and cyanidation.

Galvanized sheets are made by passing black sheets of steel, after the surfaces have been thoroughly cleaned and prepared, through pure molten zinc. By this process the surfaces are uniformly covered with an adherent coating of zinc, which entirely excludes the oxygen and moisture of the atmosphere, and inasmuch as the solution pressure, or, in other words, the corrodibility of zinc is very low, the life of such a sheet under weather conditions, even without being painted, is remarkably long. In addition to the direct exclusion of the elements, zinc has another property that makes it an excellent protective medium for iron and steel. When two dissimilar metals are coupled together and exposed to an electrolyte, an electric current will pass from one to the other, due to the difference in potential of the two metals. And the one which is electro-positive to the other will waste away while the electro-negative metal will not be acted upon. Zinc is electro-positive to iron or steel. Thus it will be readily seen that when the two metals are in contact and exposed to the weather, we have all the conditions of a simple battery, the moisture acting as the electrolyte and a minute current passes from one to the other, and the electro-negative iron or steel is protected at the expense of the zinc.

Concentration of Gold in Bottoms in the Converter

By H. F. COLLINS

*Experiments have been made from time to time in the direction of utilizing the gold contents of converter copper not rich enough in the precious metals to make electrolytic refining profitable, by means of a partial oxidation of the bath of white metals to 'pimple' metal and 'bottoms,' and the separation of the latter before completing the oxidation. Hitherto, however, the method has never come into regular use, partly, perhaps, because copper containing much gold usually contains also silver, which is not concentrated in bottoms to any great extent, and so far as I am aware no results have been published.

The method invented and patented by M. David, namely, the use of the 'selecteur,' a bowl-shaped pocket provided with separate tap-hole and fixed to the converter, into which the refined bottoms were collected by turning the converter partly down, so that upon turning up again the 'pimple' metal returned to the bottom of the converter while the copper remained in the pocket and could be tapped out separately, has not been extended beyond the original works where it was first tried, and I am not aware whether or not the 'selecteur' is still in use at those works.

Another method tried experimentally with some success is that of turning down the converter after partial blowing, and pouring the supernatant 'pimple' into a ladle for transfer into another converter, leaving the small charge of bottoms to be poured separately, either by itself, or after another charge of metal has been similarly blown, so as to accummulate a sufficient amount of bottoms for pouring. This method is quite practicable, but it introduces an additional complication into the routine of the converter plant, which is generally pushed to pretty near the capacity of the existing stands, and it introduces a difficulty in that the loss of heat in transfer is generally so great as to interfere with the finishing of the charge. 'Pimple' is notoriously difficult to blow unless exceptionally hot; upon blowing in the second converter after transfer great noses are apt to form on the tuyeres, and the charge is liable to freeze unless it be heated up by addition of some low-grade matte or sulphide ore, which has the disadvantage of reforming slag upon charge which has been skimmed clean.

The simple method devised by me, and carried out in actual practice since the summer of 1914 in small acid-lined converters, is that of providing the converter with a cast-iron tapping-block fixed opposite the tuyeres, having a tap-hole 1½ in. diam. When the lining is being rammed this hole has an ordinary ¾-in. steel bar pushed through up to within an inch of the mold, so that the lining may be rammed round it as tightly as possible, and when the molds are removed the bar is at the same time withdrawn in order to facilitate 'drying out.'

When the converter is placed upon the stand for use the tap-hole is closed by a plug of clay, and a short ¾-in. bar is then driven in so as just to protrude inside the lining while the head stands out some 16 to 20 in. from the front of the converter-shell. After blowing to precipitate as metal the required quantity of copper, the converter is turned down till the bar stands at about 75° from the horizontal.

After knocking it in an inch or so in order to penetrate any skin of copper that may have formed on the inside, the usual ring and wedge are affixed, and the bar is driven out as quickly as possible by rapid blows; as its point leaves the converter-shell the mold car held in readiness at the back is rapidly pushed forward, while the converter is at the same time turned until the tap-hole is vertical.

After one, two, or three molds have been filled, according to the size of the charge, and the issuing stream is evidently white metal and not copper, the converter is turned up as rapidly as possible, the tap-hole being plugged with clay while in motion until the next operation, and blowing is re-started to finish the charge as usual.

The success of this operation as carried out in small acid-lined converters (the so-called 3-ton size) depends primarily upon running the charge hot, not losing too much time in skimming, and not adding too much cold scrap after skimming, so that the reduced copper is at a temperature much above the melting point of the 'pimple' metal, otherwise it is liable to chill in the tap-hole. Provided the charge is hot enough, all that is required is smartness on the part of the attendants in getting out the bar quickly and in carrying out the various movements necessary.

At first, owing to lack of smartness in driving out the bar, the copper in many cases would chill in the tap-hole, and after driving and withdrawing the bar repeatedly could not be got out, so that in order to avoid chilling the charge it had to be finished in the ordinary way without getting any bottoms. After a month's practice, however, with the help of a small bonus on each charge of bottoms successfully tapped, the men have become so expert that they seldom miss getting out the bar smartly and tapping a charge from 60 to 120 kg. of bottoms without spilling more than a few kilograms of metal on the floor, and without delaying the finishing of the charge more than two or three minutes. The method of tapping the converter for bottoms is therefore no longer experimental, but has taken rank as a working method.

*Abstract from paper read before the Institution of Mining and Metallurgy, London, on May 20, 1915.

= oz. per ton.			5½	48·3			0·26	26·2					

As regards the concentration of gold in the bottoms, in practice it is easy to recover 70% of the gold originally existing in the charge in the form of bottoms, amounting to 9% of the total weight of copper produced, and 25 times as rich. The richness of the bottoms in gold depends upon the relative proportions of bottoms and residue-bars from each charge, and the following table gives the results of the first few charges tapped, omitting three or four in which the bottoms could not be got out, owing to chilling in the tap-hole.

In this table all the assays for gold and silver are given in grams per metric ton of 1000 kg., which is not only scientific and highly convenient to those who are accustomed to metric weights, but it is the system in common use in Spain and most other European countries as well as in Spanish America. One troy ounce is 31.1035 grams.

As will be seen, the richest bottoms were those of charge No. 6, which contained at the rate of 1976 gm., or over 60 oz. per ton. The quantity, however, was so small that the concentration of gold was imperfect, only 44%. Even this, however, is a noteworthy result, considering that the bottoms represent only one two-hundredths part by weight of the total charge. A more remarkable result is that of the first charge blown, which yielded 12½ kg. bottoms assaying 1216 gm., or nearly 40 oz. per ton, in which small quantity, only 2% by weight of the entire charge, no less than 74% of the total gold present was concentrated. The third charge apparently shows a very poor concentration, but in this case there is no doubt that the greater part of the bottoms remained behind in the converter, owing to not turning down far enough during the tapping pour, or to turning up too soon, and so contaminated the residue-bars instead of being recovered as bottoms.

The highest degree of concentration appears to be reached when the bottoms amount to 15% of the total copper produced, in which case they carry about 85% of the gold present. Good results in practice are, however, attained when of the total copper produced only 10% is 'bottoms' and 90% 'residues,' provided that in every case the whole of the bottoms is poured clean, and none left to contaminate the residue. The recovery of gold still averages 65% of the total present even when the proportion of bottom is only 8% of the total copper recovered.

Table II shows the actual results obtained from a large number of *consecutive* charges tapped during a part of the month of December 1914. It will be noted that once the workmen have acquired the necessary experience great variations in the weight of bottoms tapped from each charge are rare, and the proportion of the total gold concentrated in the bottoms is fairly regular. The average rate of concentration would be even better, but for the fact that in order to avoid tapping a large quantity of 'pimple' metal with the copper, all of which would have to go back to another charge as scrap, a portion of the reduced copper is sometimes allowed to stay behind in the converter, and so contaminates the residue-bars. In some cases, however, when the operation has been properly conducted the residue copper has been got as low as 2 gm. per ton, while still showing a concentration of 90% of the gold in the bottoms.

In order to obtain good results, it is necessary to hit the point of 'white metal' with considerable nicety before the final skimming prior to commencing the blowing for bottom, since if the white metal is low and contains more than 4% iron, as occasionally happens when the skimmer is either careless or timid, the time required for oxidation of the excess iron will vitiate the calculation of that required for blowing to 'bottoms'; and insufficient copper will be reduced. Provided, however, the point at which the white metal is skimmed be kept fairly uniform, it is only necessary to proportion the time for 'bottom-blowing' roughly to the size of the charge. In the particular case under consideration where the bars weigh 70 kg. a very small first charge of only 10 bars will have enough with 17 to 20 minutes, whereas a charge of upward of 20 bars will require from 24 to 26 minutes.

The concentration of silver in the bottoms is, as the tables show, and as might be expected, comparatively poor, the average assay of the bottoms being 1497 and of the residues 924 gm. per ton. So far as it goes, however, it is an advantage, since it gives to the bottoms an extra value of something like $10 per ton. The average percentage of copper in the bottoms is about 98% as compared with 99.15% for the residue-bars. This is due to imperfect elimination of such impurities as Fe, S, Pb, Ni, As, etc., from the first copper reduced, and is of no importance, seeing that the bottoms in any case have to be refined electrolytically.

TABLE I

21	129.0	152	1252	874	4	588	19.61	3.50	23.11	23.0	84.9
20	135.0	128	1064	607	4	540	17.28	2.43	19.71	26.5	87.7

In the case of copper that contains, say, ½ to ¾ oz. gold and not much silver, it is evidently a great advantage to be able to concentrate, *at practically speaking no additional cost*, from two-thirds to three-fourths of the gold into 8% by weight of bottoms for electrolytic refining, and worth at least $120 per ton more than the original copper, the remaining 92% of the output taking the form of residue-bars, practically free from gold, and which therefore can be refined in a reverberatory direct to 'best selected' copper and sold as such.

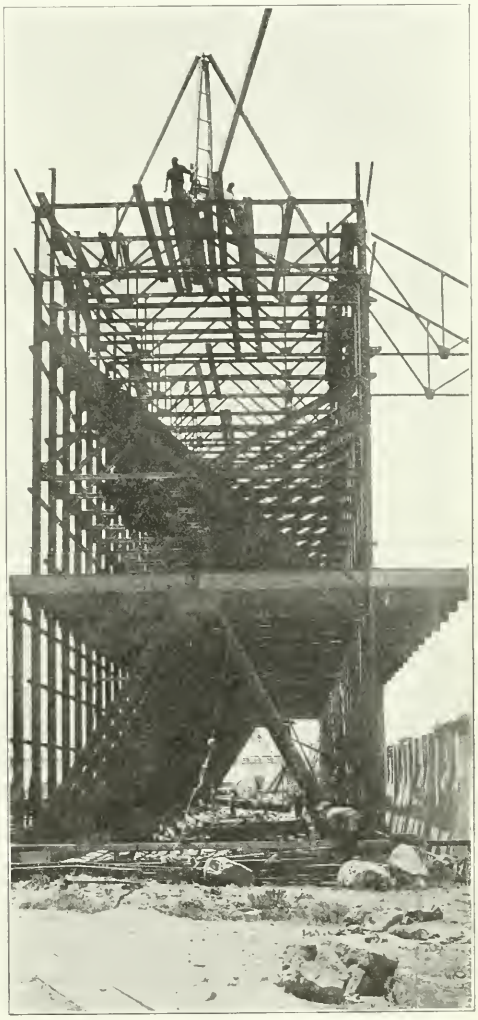
The method of gold concentration in converter-bottoms described is no longer experimental, but has become standard practice at Cueva de la Mora since the month of November 1914; it is rumored that a neighboring plant intends to pay us the compliment of experimenting in the same direction.

I take pleasure in acknowledging the valuable assistance received from my metallurgical assistant, Mr. William Spalding, in carrying out these experiments, and in installing the method as part of our regular routine. [The theory of this process has been studied by Edward Keller, *Mineral Industry* vol. IX, P. 240, *Trans.* A. I. M. E., vol. XXVIII, 127. also by Allen Gibb, 3rd Report Alloys Research Committee, Institution of Mech. Eng., 1895.—Editor.]

Ore-Bin Construction

There are many types of ore-bins in stamp-mills throughout the world. Some engineers prefer flat-bottom bins, others sloping, and others again half flat and half sloping. Flat bins give additional storage. Sloping bins are self-emptying. Ore-bins have great weights to hold, besides the impact of ore being continually dumped into them, either out of cars or from belt-conveyors. The vibration from the stamps is also a strain on bins. The support of a bin is all-important. Bins sometimes collapse from lack of sufficient supports. They are generally built of wood, except in smelters, where they should be of steel. The accompanying photograph shows a large steel bin being erected on the Rand. It is of the sloping type, well braced under the joists. The camshaft floor is part of the structure, being visible above the concrete foundations for the mortar-boxes. The wear on a wooden bin is heavy, especially on the floor and around the discharge-gates. There is also the liability to catching fire. Steel bins might be attacked by acid in the mine-water mixed with the ore. They would probably take longer to erect than wood, and may cost more where wood is cheap. But they offer several advantages over wooden ones. On the Rand, timber is expensive, Oregon pine being used for the most part. Recent practice is to use steel and concrete to a large extent. Bins may be wholly of steel, or a steel frame lined with wood. Good foundations are highly important, and the posts should be fitted into steel or cast-iron plates bolted to the foundations. Ore-bin design offers much opportunity for study to engineers and the importance of the matter justifies careful attention.

The deepest well in the world is in Upper Silesia, in Germany. It is a diamond-drill hole in a coalfield and is 7350 ft. deep. A well in the United States which may go deeper, according to the U. S. Geological Survey, is four miles northwest of McDonald, Pennsylvania, and about 15 miles west of Pittsburg. This well, which is being sunk to the Medina sandstone—a bed that elsewhere contains oil and gas—is now 7174 ft. deep. Some



STEEL ORE-BIN CONSTRUCTION ON THE RAND.

gas and oil were found in the upper part of the well. Between the depths of 6830 and 7100 ft., rock-bearing salt and salt water were encountered. These are regarded as of Salina age, the same as those carrying rock salt in western New York. The temperature in this well at the depth of 6775 ft. is 145 °F.

Testing Working Cyanide Solutions

According to Edward H. Croghan in the April issue of the *Journal* of the Chemical, Metallurgical, and Mining Society of South Africa, great diversity of results may be obtained in testing working cyanide solutions, and a suitable uniform procedure which should be adopted on the Rand is highly desirable.

In working solutions with zinc precipitation in vogue, solutions containing both free cyanide and cyanide existing as double zinc cyanide, there are in titrating with silver nitrate in the presence of potassium iodide as indicator, two end points that can be observed: (1) the first appearance of a distinct opalescence or permanent flocculent whitish precipitate; (2) following on (1) the appearance of a distinct permanent yellowish tint. The first point is presumed to approximately give the figures for free cyanide content, and the second depending chiefly on whether there is present or not sufficient free alkali and the dilution, the whole or a part of the total cyanide. Subsequent references to the above two finishing points will be briefly termed the white and yellow points, respectively.

There does not seem to be uniformity in the matter of testing. It is in consequence interesting to note that, supposing a test were made on a strong solution to the yellow point, and 0.12% KCN found the more correct result for *free* KCN, if the titration had been conducted to the white point, might only be 0.06%. On slime solutions the same result could occur, 0.015% KCN according to the yellow point might not be on the white more than 0.008% free KCN, and possibly less.

In the course of testing some working solutions for free cyanide, he noted the percentage of so-called free cyanide according to the white or yellow points previously referred to, and continuing the determination for protective alkali on the same solution which had been titrated by silver nitrate with potassium iodide as indicator.

The tests made result in the following conclusions for KCN: (1) The white point results of both methods are much lower than those of their respective yellow. (2) The yellow point data of the ordinary method are a good deal higher than those of the yellow under the special process—in fact, the former almost correspond to the total cyanide found, particularly on the weak solutions. (3) The white point percentages of the ordinary method fall interestingly between those of the white and yellow of the special procedure, with two minor exceptions. From the analyses it is indicated that neither the white nor the yellow point data of the special method can lay claim to being in closer agreement with those of the white point of the ordinary procedure.

Regarding protective alkali, the following is deduced; (1) Comparing the protective alkali results obtained by the ordinary method on solutions which had been titrated for free cyanide, that is, to the white point, with those of the special method, on the weak cyanide solutions the agreement on the whole is close, but on the stronger the former tends to be higher. (2) The protective alkali figures found under the ordinary method on the solutions titrated to the yellow point with silver nitrate, are on the average distinctly lower than those secured on the white point of the ordinary, and seemingly, though to a lesser extent, lower compared with the data yielded by the special method. The estimation of protective alkali on a yellow point solution is very unsatisfactory owing to the disappearance and slow faint reappearance of the purple-red of the phenolphthalein indicator, in fact any result might be obtained on a quick titration and not looking out for this recurrence. His titrations were slowly done until after about a quarter of a minute no trace of color developed. If in the titration with silver nitrate in the first instance the yellow point be overdone, and it is fairly easy to do so in a bad light, the protective alkali figures will be found to be much lower. One of the theories advanced is that the lower alkalinity estimated may be due to the formation of zinc nitrate, which in turn would react with the alkali, and so lessen its amount. Under the special method of determining the protective alkali, this difficulty is obviated chiefly by the addition of a slight excess of potassium ferrocyanide, which regenerates the alkali. Mr. Croghan discussed Clennell's remarks on the finishing point of permanent yellowish turbidity.

The following methods were employed by the author:

Standard silver nitrate=6.523 grams per litre. Using 50 cc. sample for testing, 1 cc. standard silver nitrate =0.01% KCN.

Ordinary method for free cyanide: to 50 cc. sample add 5 drops of 10% solution of potassium iodide. Titrate with standard silver nitrate to first distinct flocculent whitish precipitate, which after agitation remains permanent for about half-a-minute.

For protective alkali: to the solution used above for free cyanide, add 8 to 10 drops of 0.5% neutral alcoholic solution of phenolphthalein and titrate with standard acid as usual until the color has quite disappeared. For the yellow point results proceed on similar lines.

Total cyanide: to 50 cc. sample add 5 to 10 cc. of 4% solution of sodium hydrate containing 1% potassium iodide; titrate with standard silver nitrate to yellow tint.

Special method. (Clennell) free cyanide: (1) Determine the total cyanide as above. (2) To another lot of 50 cc. sample, add slightly more (about 0.2 cc.) than the amount of silver nitrate found to be required for the total cyanide, together with a slight excess of potassium ferro-cyanide. Then 8 to 10 drops of phenolphthalein are added to the turbid liquid and the mixture titrated (without filtering) with standard acid (*N*/10 sulphuric acid) until the pink just disappears. (3) To a third 50 cc. of the original sample add gradually with agitation the amount of acid required under (2). Five drops of 10% potassium iodide solution are then added and the mixture titrated with silver nitrate until a distinct flocculent whitish precipitate remains permanent for about half-a-minute.

Protective alkali: this is the result as found under (2).

Concentrates

Readers of the Mining and Scientific Press are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

Centrifugal force comes into play when the speed of a belt exceeds about 4000 ft. per minute.

Flotation, apart from crushing of the ore and treatment of the concentrate, costs about $1 per ton at Broken Hill.

Salt lake is 5½ times more salt than the ocean and the density of its water is 14.5% greater than that of fresh water.

Playa is the name given to shallow flat-floored depressions, characteristic of valleys having no regular drainage to the sea.

Gypsite is finely divided gypsum, lime sulphate, mixed with other matter that does not interfere with its use for cement plaster.

Bentonite is a white clay of the finest quality found in the Benton shale of Wyoming. It is used in antiphlogistine; also to adulterate candies and drugs. It will absorb seven times its volume of water.

Common gases in coal mines are as follows: carbon dioxide (CO_2), carbon monoxide (CO), ethane or olefiant gas (C_2H_6), ethene (C_2H_4), hydrogen sulphide (H_2S), and methane or marsh gas (CH_4). Hydrogen, nitrogen, and oxygen also occur in these gases.

Columnar structure in rocks, notably basalt, is due to contraction on cooling. The prismatic shrinkage-cracks start at right angles to the cooling surface. If the rock were perfectly homogeneous and cooled uniformly, the columns would all be hexagonal and of uniform thickness.

Metal sheet roofs are clean and sanitary, so that, where necessary, water from them can be collected into cisterns used for domestic purposes. Having no gravel and tar the surface is not apt to clog up eave trough and conductor pipes as is often the case with so-called 'slag' roofs.

That ordinary dynamite and gelatin dynamite will freeze, and become less sensitive at temperatures between 45° and 50°F., is well known. It is not so widely understood that such dynamite may be chilled to an extent that materially lessens its effectiveness without becoming hard, and without exhibiting any physical difference that would readily distinguish it as being in poor condition.

Refining gold by chlorine gas, as practised at the three mints in Australia is well adapted to the rapid refining of gold alloyed with varying proportions of silver and base metals. The latter may include every metal known. The process is applicable to bullion containing from 99% gold, 1% silver and base, to 1% gold, and 99% silver and base. Chlorine gas of 5 to 6-lb. pressure is suitable. All base metals are converted into chlorides and expelled, and silver chloride floats on top of the pure gold.

Advantages of the electric-furnace compared to the blast-furnace for melting high-grade gold slags are as follows, according to W. P. Lass: a saving in mechanical loss of gold in flue-dust, because the melting is done in a quiet neutral atmosphere, instead of in a rising blast of air; the obtaining of a lower-grade slag, free from shot, by reason of the quieter melting action and the higher temperature obtainable, making a more fluid slag; the nicety of regulation of the melting temperature; and the benefit to the general health of the operators.

Link-belting is made of short lengths of selected leather united by rivets around which the links pivot. This gives a flexible belt suitable for short drives, for which rigid leather belts would be unsuitable, but it is, of course, also adapted to heavy main driving. In the transverse direction link-belts are too rigid to lie round a curved face. But by fitting a flexible series of double links down the centre, with or without curving of the other links transversely, they will fit pulleys having a large amount of crowning, without slip of the belt or strain of the rivets. There is no air-cushion when a link-belt is running.

Copper added in small quantities greatly prolongs the life of iron. Very small quantities are needed to effect this result. If to one thousand pounds of iron, two pounds of copper be added, the resulting alloy will dissolve in acid only one-tenth as fast as pure iron does; and in the atmosphere the corrosion will be only one-third as rapid. An increase in the copper up to 7% of the alloy does not increase the power of the iron to resist corrosion. Copper, 0.2%, will yield as good an alloy for resisting rust and corrosion as does 7%, and the resulting alloy is less expensive on account of the smaller amount of copper required.

In acetylene gas manufacture, calcium carbide wetted with water, considerable quantities of so-called carbide slime are always left in producers. The slime is a waste product, no means of utilizing it having been known heretofore. In view of the large increase in the consumption of acetylene since the outbreak of the War, the report of R. Schumann on the possible utilization of carbide slime, published in the *Chemiker-Zeitung*, will be of special interest. The material could not be used as fertilizer, salts of phosphorus being absent, but might be used as water purifier when of a certain composition. The experiments with the employment of carbide slime as building material yielded the best results. When mixed with 40% of building sand, the carbide slime formed a usable mortar which set well and bound the bricks firmly. This new building material will be thoroughly tested by further experiments.

Japanese Minerals at the Exposition

The Japanese mining exhibit at the Panama-Pacific Exposition is one of the most attractive and instructive to be seen there. As it has been made by the Government with the cooperation of the mining companies, the individual exhibits were not entered in competition for the prizes, and a special commemorative medal has been awarded to the exhibit as a whole. A clear understanding of the status of the mining industry of Japan can be obtained from the exhibit of the Imperial Geological Survey. This includes a systematic collection of the minerals and fossils of Japan, supplemented by a similar collection of the economic minerals of Japan. Large maps and wall-diagrams make clear the significance of these, and the publications of the Survey are also on view. Of more popular interest are the photographs and relief-models of Sakurajima, showing the crater before and after the eruption of 1913, which resulted in the loss of so many lives. These are supplemented by blocks of lava, volcanic ash, tufa, and lapilli thrown out during the eruption. A similar exhibit is made for the volcano called Aso.

The largest mining company in Japan is the Mitsu Bishi & Co., which owns 15 metal mines, producing copper, gold, silver, lead, zinc, tin, and tungsten, and 8 coal mines, the value of the annual production in 1913 being $18,500,000. This company has filled a large case with a systematic collection indicating its various activities. Coal, copper ore, iron ore, blister copper, anodes, refined copper, copper sheets, blue vitriol, printing-rolls made from copper, and various other finished products are shown. Some unusually fine mineral specimens are displayed, proving the great variety of ores mined by this company. Furukawa & Co., the largest copper-mining company in Japan, has made an especially attractive exhibit. Copper ore from the Ashio and Kobe mines is shown in quantity, also coal from the three collieries owned by this company. Of the various copper mines a typical block of ore is exhibited and next to it is a bar of the blister copper made at that mine. The central feature of the exhibit is a collection of the finished products made from copper for which the Furukawa Co. has a high reputation. Those shown include copper wire of various sizes, trolley wire, copper rods and bars, and copper and brass sheets. This company owns 10 metal mines, producing copper, silver, gold, coal, lead, and zinc. The value of its output in 1913 was about $6,000,000.

The Mitsui Mining Co., which owns 5 coal mines and one silver-zinc mine, has made an excellent exhibit. Blocks of coal from its various collieries are displayed, coke from washed coal, heavy oil, creosote, light oil, napthalene, and ammonium sulphate in jars. Large samples of wolframite ore are on view, together with the concentrate therefrom. Crude and refined sulphur is displayed in large glass jars. Zinc-lead ore from Kamioka is shown together with bars of spelter. Electrolytically refined lead and bismuth are on view. The value of its products in 1913 was $7,000,000.

The neighboring case displays the products of the Sumitomo mines and works. Various samples of ore from the Besshi mine are shown, copper ingots, copper wire, sheets, and tubes, and brass wire, sheets, and tubes. The case is well arranged and is especially attractive. The operations of this company were described in the Mining and Scientific Press of September 21, 1912. Production in 1913 was valued at $3,500,000.

The Kuhara Mining Co. exhibits large blocks of ore from its various mines, with a display of copper cathodes, pigs of copper, and bars of silver bullion in the middle. Fujita & Co. has a similar exhibit, including blister copper, cathodes, bullion, also zinc oxide pigment, zinc dust, and zinc white for face powder. This company owns six mines and its production in 1913 was valued at $5,000,000.

The Imperial Steel Works has made a comprehensive exhibit. An exact model of the plant at Wakamatsu gives a clear idea of the magnitude and scope of operations. This is supplemented by photographs. An adjoining case contains blocks of iron and maganese ore, dolomite, firebrick, coke, and by-products from coke-ovens. Another case shows the various iron and steel products made by the plant.

Chobei Tanaka shows samples of iron, copper, and gold ore, coke pig-iron, charcoal pig-iron, steel bars, round and flat, angles, and rail sections. At its Kamaishi mine, this company produces pig iron, ferro-manganese, copper, silver, and gold, valued at over $2,000,000 in 1913.

The Hokkaido Colliery & Steamship Co., Ltd., has filled a large showcase with large blocks of coal from its various collieries, Sorachi, Yubari, and Manji, and pig iron made at its iron works.

The Nippon Oil Co. shows photographs of its wells and refineries, also jars of the numerous products made in refining. The exhibit is especially instructive since a jar of crude from each of the four productive districts is shown, and beside it other jars contain the relative amounts of gasoline, kerosene, light oil, and heavy oil. The output in 1913 was valued at about $2,000,000.

The Japan Sulphur Co. exhibits large blocks of crude ore, sulphur in large rolls, also flowers of sulphur, and the packages of sulphur packed for shipment. The Kaijima Coal Mining Co. exhibits large and small cubes cut from coal that are perfect enough to serve as building-stones. The Meiji Mining Co. has constructed a small mountain of coal, on which native miners are at work. A sample of gold ore from the Shojo mine, Korea, owned by the same company, is also exhibited.

Oregon Minerals at the Exposition

During June a display of minerals of Oregon was arranged in the Palace of Mines and Metallurgy at the Panama-Pacific Exposition. To enlighten visitors, the Oregon Bureau of Mines and Geology, H. M. Parks director at Corvallis, prepared a 40-page illustrated pamphlet for distribution briefly covering mining in the State. In 1913 the total mineral production of the State was valued at $3,563,919. Gold contributed $1,627,710 of this and clay and stone over $1,000,000.

In the centre of the exhibit is a relief map of the State. Posts at the corners are surmounted by glass jars of gold, copper, and lead-silver ores. In cases surrounding the booth are the following: (1) Coarse gold from the Powder River dredge at Sumpter. At present this is the only boat in Oregon. Its daily output is 50 oz. (2) Gold ore, mill products, etc., from the Union-Companion mines of the Cornucopia Mines Co., Baker county. With 75 men, 20 stamps, and cyanide plant, the annual output is $330,000. Ore, some showing tellurides, is also shown from the Last Chance mine of the Baker Mines Co. (3) Nugget weighing 80.4 oz., found at the Buck Gulch placer, Grant county, June 19, 1913; crystallized and leaf gold from the Humboldt mine, Malheur county; also Belmont mine, Grant county. Quartz gold pebbles from the Daggett placers, Grant county; platinum from Logan property, Josephine county, the largest platinum producer in the United States; ores and native copper from the Waldo district, Josephine county; and opal in matrix. (4) Specimens of petrified wood, marbles, granites, lime, and gypsum. (5) Samples of shell marl from Scappoose, Columbia county, used in cement manufacture; quicksilver and other ores. (6) This case is interesting from the old Indian pestle and mortars shown. On two sides of the relief map mentioned are six benches of four tiers each containing large samples of gold, copper, antimony, chrome, and other ores. Three cases display good polished stones and gems. The coal industry is represented by large pieces from Beaver Hill, Coos county. The sandstone of Lincoln county is shown, but in a larger way at the Call building, San Francisco, which was built entirely of it. Photographs of all phases of Oregon mining complete a well-arranged collection of minerals.

Placer mining has had a good season this year. A railway in the southeast is expected to stimulate languishing districts.

REVIEW OF MINING

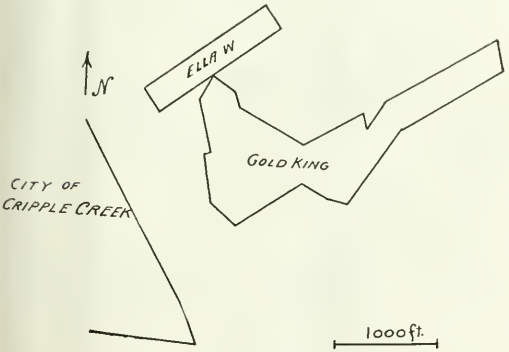
As seen at the world's great mining centres by our own correspondents.

CRIPPLE CREEK, COLORADO

Residue-Covered Claim Starts Suit.—Stratton's Independence.—Last Dollar.—Ella W. Discovery.—District Situation.

Stratton's Independence, Ltd., has been made defendant in a suit brought by Mrs. M. E. Brooks, of Denver, in the United States district court. It seems that the plaintiff owns a fractional mining claim adjacent to the Independence tailing-pond. For some time past residue from the mill has been dumped close to and partly on this claim. The plaintiff asserts that her ground has been damaged to the extent of $25,000, the amount sued for. It is well known that no work has been done on the claim for more than 10 years. The tailing has been on the ground for several years and nothing has even been said about it. Since the strip of ground claimed to be covered is about 50 ft. long, it is hard to see how damage to this amount has been done.

Much activity is being shown at the Independence mine. About 15 sets of lessees are already working. Some of them have a fair grade of ore opened. Numerous other parties are



PLAN SHOWING POSITION OF ELLA W. MINE.

looking over their blocks, trying to determine the most advantageous way of opening them. Development is being vigorously prosecuted on company account.

It is reported that the shaft on the Last Dollar property will soon be sunk another hundred feet.

Much interest is being shown in the development recently made at the Ella W. property on Tenderfoot hill. This claim lies just northeast of the city limits of Cripple Creek, and closely adjoins the Gold King claims. It was on the latter group that the first discovery of gold was made in the district. On the Ella W., lessees have opened on the surface an ore deposit the dimensions of which are still undetermined. The pit so far is about 12 ft. wide, and still there is ore on both sides. In length the ore has been taken out for about 50 ft., with no signs of the ore cutting out in either direction. From the surface it looks like a huge blow-out. The ore is an oxidized porphyry, and pieces can be found which show flakes of free gold. The first shipment from the open-cut settled for a little less than $20 per ton. Two other shipments have been made, but the returns have not yet been received.

The general condition of the district is quiet with steady output. If the deposit at the Ella W. proves persistent and near the present value, it will mean considerable activity in a part of the district which has long been quiet.

TORONTO, ONTARIO

Porcupine and Cobalt Mines' Development.

Dome shares have recently shown a strong upward tendency. The advance is shared by other Porcupine issues. On the other hand, Cobalt shares were generally weak and inactive. The cause of this is the reduction in the price of silver. The increased interest in the Dome is due to reports of a decided improvement in the grade of the ore being developed on the fifth and sixth levels. This is stated to be worth about $10 per ton for a distance of 200 ft.——At the Vipond a rich shoot has been opened in the Davidson vein at 200-ft. Good ore has been cut in the winze being put down from 300 to 400-ft. but the vein faulted at 48 feet.

The Porcupine Crown has materially added to its ore reserves. The fault in the vein has disappeared at the 600-ft. level, where the vein shows increased width and retains its grade.——As a result of their recent visit of inspection to the mine the directors of the McIntyre have determined to sink to 700 ft. without delay.——The structure of the Schumacher mill has been completed, and the machinery contracted for. A vein 4½ ft. wide has been cut in cross-cutting toward the McIntyre boundary at 300 ft.——At the Miracle mine, where work was started a couple of months since, four veins have been found. A shaft on one of these is now down 25 ft. Samples assay $9 gold per ton, also some silver.——The Huronian Belt company is adding to its steam plant at the North Thompson, having ordered a 125-hp. boiler. This will make a total of 225 hp. A three-compartment shaft is down nearly 200 ft.——Rich ore has been found in the shaft on the Wright property now down 40 ft. A cross-cut is being driven to determine the width of the orebody.

Cobalt activities are as follows: The Nipissing and La Rose companies have declared their usual quarterly dividends of 5 and 1% respectively.——The Columbus Cobalt is cross-cutting at the 400 ft. level to find some veins which show on the surface.——The Peterson Lake is driving on a smaltite vein found at 160 ft. It shows improvement as work progresses, some assays being 500 oz. per ton.——Active development has been resumed at the Adanac, formerly the Pan-Silver property. Cross-cutting is in progress at 200 ft. One good vein has been cut.——The Silver Queen has been leased to a Cobalt syndicate on a royalty basis.——At the Silver Leaf high-grade ore is being extracted from the 125-ft. level. A large tonnage of milling ore is ready for concentration.—— The lease held by the Glen Lake company on the old Foster mine has been extended for an additional five years, giving the company control for a total term of nine years, with a royalty of 15% on 200-oz. ore and under, and 25% of net proceeds on ore of higher grade.

Development accomplished in the Beaver mine during the quarter ended May 31 totaled 1318 ft. The main shaft is down 1000 ft. It is to be continued to the diabase and lower contact. The mill is being increased to 150-ton daily capacity. Cash on hand amounted to $79,847. The recent trouble with the power company has been settled, for the time being, and operations are practically under the old conditions.

PETROGRAD, RUSSIA

Present Condition of Gold Mining in the Empire.—Turkestan Minerals.—Manganese.—Copper Production.—Yakutsk Minerals.—Platinum.—Graphite.

For many reasons it is very difficult to discuss the present condition of gold mining in Russia. These may be stated briefly as follows: first, the gold industry extends over such immense areas as to make the collection of statistics even under normal conditions, exceedingly complicated; second, then there is the fact that the Russian idea of statistics, although in many respects remarkably meticulous, has not extended to the comprehensiveness that is required to give an accurate idea, or anything approaching thereto, of the progress of the industry as a whole; and third, the system of clandestine removal of the metal beyond the knowledge of Government control, largely contributes to doubting even the most carefully prepared figures on the industry. Statements are continually being made that the Russian gold industry is in a bad way; and it of course admits of no misunderstanding that as far as foreign concerns engaged in exploiting the Russian goldfields are concerned they have no particular reason to congratulate themselves or their shareholders. It was stated not long ago by a Russian minister, however, that although it was becoming a habit to speak of a decline in the gold production of the empire, the statement is essentially an erroneous one. He pointed out with a show of justification that its progress has been irregular, and the tendency in the case of a setback is to give the pessimists an inning until new figures, that is to say, the results of later operations, show that such setback has been due, in all probability, to exceptional circumstances. On the whole, he contends, the gold industry of Russia is making progress, although progress is slow.

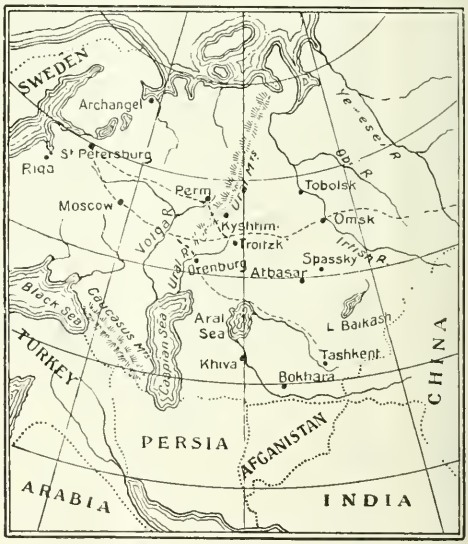
Upon this observation, the *Novoye Vremya*, the leading Russian newspaper, has studied the situation. It quotes from reliable statistics dating from the time when gold mining started in Russia, in the forties of last century, and carried down to the year 1903, during which time the industry had progressed regularly, and during several periods with considerable rapidity. During that period the production of gold in the Russian Empire rose from about 1500 to 4000 poods (700,000 to 1,867,000 oz.), per annum. These last figures are true, at all events, of the years 1900-1902. But it is clear that the irregular returns give an unfavorable impression. It was about at that time that the production of gold began to decrease rapidly. It is now as low as 1,400,000 oz., this for 1913. One may state, says the journal, with all confidence, judging from data that are available, that the decline of 1914, must have been considerable. Particulars received from the Orenburg government, Miask, Verchne-Uralsk, etc., show the decrease compared even with the relatively low one of 1913, to have been serious. The *Uralskaya-Zhisn* says, in connection with the alarming state of the gold industry, many mines have ceased producing altogether; and this is so marked that large areas that used to be desert land in the forties, and had been reclaimed from that condition owing to the development of the gold industry, have relapsed into their then desert condition, as the only value that such land had was the gold it contained. It is to be feared in view of the great disturbance to industry as a result of the War, that such a recovery as might have been expected from the infusion of foreign capital and enterprise during the next few years will not likely take effect until the country has had time to settle down, and the staple industries have recovered something of their normal capacity.

A statement issued on the gold production of Russia in 1914 shows that the quantity of gold slime received in the Treasury smelting laboratories amounted to 1,385,000 oz. against 1,283,000 in 1913, equal to 7.9%. The delivery of gold during the last four years has been irregular. It amounted in 1912 and 1913 to less than in 1911, while that of 1914 was the maximum.

The dominating position in the gold yield is held by eastern Siberia, where the quantity produced in 1914 greatly exceeded that of 1913, while on the contrary, the output in the Urals and in western Siberia fell compared with 1913. The following table shows the relative importance of the gold producing areas as recognized in the country:

	Eastern Siberia	Western Siberia	Urals	Total
	oz.	oz.	oz.	oz.
1911	1,125,000	99,600	69,600	1,294,200
1912	998,000	105,000	100,000	1,203,000
1913	1,066,000	108,000	109,000	1,283,000
1914	1,194,000	107,000	84,000	1,385,000

The fine gold content in 1914 was 1,164,000 oz. If the gold melted in private laboratories, (results from which are not available) but about equal to that obtained from similar sources in 1913, that is, about 512,000 oz. the total production of fine gold in Russia in 1914 would be 1,676,000 oz. Gold production in the Urals has fallen away considerably on account



----------RAILWAYS. ..... BOUNDARIES.

PART OF RUSSIA AND SIBERIA.

of the shortage of labor. In western Siberia the decline was chiefly in the Tomsk district. In eastern Siberia the increase was mainly in the largest gold-producing area in the Empire, namely the Bodaibo. In the Irkutsk and other districts the yield fell in one area, the Zeisk.

With this gold the following quantity of silver was obtained in Treasury laboratories: Urals, 22,000; western Siberia, 18,000; eastern Siberia, 105,000; a total of 145,000 ounces.

Lapland was often thought of as the coming gold district of Finland. Results have been as follows: In 1836 gold was first found in the valley of the River Kem, and the Government provided a large sum of money to work the mines. At Enara in 1870 there were 18 mines, employing 335 men. Yield in that year was 620 oz. Next year there were 22 mines and 491 men. The output was 1890 oz. This was the maximum yield in any one year. Since 1876 production has declined. The last annual report shows a total return of 27 oz. Thus it may be considered that Lapland gold has lost all interest. The total yield in the region amounts to 15,700 ounces.

The mineral wealth of Turkestan is frequently referred to in the Russian press, and a recent discussion of the subject in

a Petrograd paper shows that these mineral reserves have been little exploited. It is known, however, that on the main arteries of the expected future routes there is coal, large quantities of manganese ore, silver-lead ore, asbestos, graphite, turquoise of fine quality and quantity, and plenty of gold-bearing sand. The last named are found on the River Vachma. They have been but little investigated. It is of interest to note that the production of gold is made by the lower classes, people without regular employment. Methods are very primitive.

A Russian mining product of vast importance that is bound to feel the effect of the War and the exclusion of Germans from their favorite fields of enterprise in Russia, is manganese, which had so largely fallen into German hands. What effect the cessation of the export of Caucasian manganese may have had on the great German metallurgical industries will not be known for some time. It is possible, as Germany was a very large importer for some years, that considerable stocks had been accumulated. The position at Chiatur, that is the manganese field of the Caucasus, for 1914 is given as follows in the *Metallurgical Journal*: The production of manganese in 1914 amounted to 40,446,000 poods (652,354 tons). This is a reduction of 18,742,000 poods (302,290 tons) on that of 1913, or 31.67%. This reduction, it may be assumed, is principally due to the military operations in which the country is engaged. In the first six months of 1914, 40,105,000 poods (646,854 tons) was dispatched from the mines, or 9.46% more than in the corresponding period of 1913. The export of manganese ore through Poti in 1914 compared with 1913, for the first eight months of the year, showed an increase of 1,824,000 poods (29,419 tons), or 7.2%, and through Batoum an increase of 135,000 poods (2177 tons), or 0.8%. The countries to which the ore was exported during 1914 were; Germany, 326,403 tons; Belgium, 154,467; Great Britain, 107,838; United States, 34,548; Austria-Hungary, 32,435; and France, 23,951 tons. As these figures but slightly exceed the exports to the respective countries during the first half of the year, it is obvious that the military operations must be held to account for the practical stoppage of business during the second half.

One metal, at all events, the production of which is growing in Russia, except the Caucasus, is copper. During the first two months of this year the total quantity of metallic copper produced in the Urals was 2877 tons, which is 431 tons more than in the corresponding period of 1914. Obviously, this increase will be in response to the demand for military uses. For some time previously there had been an ominous decline in the output of the Russian copper fields, so that this revival must be taken as altogether exceptional, and not indicative of the tendency of the industry, although in respect to this observation it must not be forgotten that it is difficult to account, all the same, for the preceding decline in the Russian copper industry, after a number of years of remarkable and progressive prosperity.

In the third district of the Caucasus, where there has been considerable difficulty in operating copper mines owing to the military situation, last year there were five copper smelters at work, as follows: Kedabek factory in the Elisabetpol government, the quantity of copper ore produced was 14,401 tons, yielding 794 tons of copper; Sisimadansky factory in the Erivan government, 154 tons of ore; Syunikshy factory in the Elisabetpol government, 644 tons of ore and 872 tons of copper, obviously from previously accumulated ore (or other than mineral on the spot) unless the figures given for the ore are incorrect; Uruchaisky factory, in the same government, copper ore 2786 tons and metal 481 tons; and Katarsky factory in the Elisabetpol government, 2131 tons ore. The total copper smelted was 2147 tons, against 3071 tons in 1913. Besides the factories with mines named, at various other mining works in the Elisabetpol and Erivan governments, 4234 tons of ore was produced, besides a small quantity extracted in development.

According to a note in the *Siberian* Echo, an engineer, N. Bosenko, who has been investigating in the Yakutsk region, has proved in that area the following deposits of metals and minerals: gold, 27; native silver, 1; graphite, 3; silver-lead ore, 15; mercury, 1; tin ore, 1; copper ore, 7; iron ore, 50; coal, 65; rock-salt, 8; salt springs, 10; Glauber salt, 2; barite, 2; asbestos, 3; fluorspar, 1; gypsum, 2; sulphur ore, 34; asphalt, 1; petroleum, 4; amber, 7; fireclay, 6; marble, 41; and precious stones (various), 65.

At a recent meeting of the gold and platinum producers of the Urals district it was decided to urge the Government to establish a platinum-refining factory as soon as possible. This question has been before the Government and the precious-metal producers for a number of years. It has been discussed many times from every point of view, but the influence of the vested interests have hitherto been too strong for a decided step to be taken, except in the form of resolutions, many of which have been vigorous enough. But the refining laboratory so long hoped for is still the subject of much desire.

In connection with the institution of a regular steamship service between the mouths of the Yenissei and Ob rivers, by the northern sea route, the possibility of developing the graphite deposits of the Turuchany district is again to the front. These deposits have been known for a long time, but efforts to work them only started a short time ago. On the occasion of the Russo-Japanese war, permission to import certain classes of goods free of duty by the Yenissei was granted. On the initiative of two persons, several thousand tons of graphite was extracted and delivered on to the bank of the Yenissee river. Shortly after the traffic from Yenissei through the Arctic ocean was stopped and the graphite was left on the banks where it had been placed.

In point of quality the Turuchany graphite was highly esteemed. It is considered much finer than the Ceylon product. Of course there is the question of the cost of production, which is perhaps exaggerated in the minds of those who consider the question. Turuchany graphite is found on the lower Yenissei along the banks of the tributary rivers, outcropping in great beds; and thus its production does not involve expensive equipment. The extra expenditure consists only in what is paid for labor, especially in view of the difficulty of providing food for the workmen. But the high value of graphite itself, and the low sea charges, can very easily support these expenses.

A further question that arises in connection with the production of this mineral is the institution of concerns in Russia for manufacturing the graphite into goods for the market, which should be considered along with the feasibility of its conveyance from the Yenissei to such points as it may be economical to deliver it at. It is even suggested that factories for manufacturing graphite might be established in Siberia itself.

An interesting correspondence comes from the Amur area showing that rich gold-bearing ground has been discovered in the neighborhood of Gonzha station, about midway on the Amur railway. The discovery has attracted a considerable number of men who have promptly staked claims. The first position discovered has been claimed by a local official. At the same time many are engaged seeking fresh deposits.

IRON RIVER, MICHIGAN

Iron-Ore Production.—Iron River Activity.—Steel Ore-Cars.—Iron-Ore Producers.

The ore business is beginning to liven up a litle. Things have been very quiet on the iron ranges during the first half of the shipping-season, but, as has occurred before, it is now hoped that increased demand will necessitate a considerable speeding up at the mines. The more optimistic are predicting an output of 40,000,000 tons, but it is not generally believed this total will be reached. Last seasou, which was unsatisfactory, only 32,790,000 tons was sent down the lakes, compared with over 50,000,000 tons in 1913. Due to the low prices

for iron ore in 1914, which were as low as in the bad years of 1912 and 1905, considerable ore mined was put on stockpile to wait until prices advanced. This accumulation at the mines has been a detriment to active mining operations during the present season, and many properties that had employed good forces for years curtailed to the oldest and best miners.

The Breitung-Kaufman mines in the Negaunee basin, which somehow were kept operating full blast during previous periods of depressions, were among those affected by the dull times of recent months; in addition, however, to the few old miners retained at these mines, several hundred more men are now being taken on. This firm is thought to have once more made good-sized ore sales in its peculiar manner. The Iron River district took on new life several weeks ago when six of the moderate-sized companies operating there re-opened their mines. This district had not known a dull period for years, and had lately been the scene of a boom in iron-mining circles, so that the energetic population of the district is much pleased

PART OF MICHIGAN IRON RANGES.

to see work resumed. At the new Balkan mine in the Crystal Falls district, Pickands, Mather & Co. is developing a large orebody taken over from the E. J. Longyear Co., which found it by diamond-drilling. The pit has been stripped to a depth of 80 ft., around the sides of which the railroad winds in a spiral after the characteristic Mesabi Range manner; a new steel head-frame has been completed at which an ore-crusher from the old Hemlock mine will be installed, and perhaps a concrete lining will be put in the shaft where it is in sand and gravel, as considerable water comes in this upper portion above bedrock. Unless unforeseen delays occur in the stripping, it is expected to ship a fair tonnage before the season closes in November. The old Hemlock of the same company at Amasa, also near Crystal Falls, which has been such a steady shipper for many years, is worked out. The equipment is being overhauled for removing such of it as is in good condition to the new Warner mine of the same company, only a few miles away, where a moderate-sized orebody has been developed. The Lake Superior & Ishpeming railway, which is owned by the Cleveland-Cliffs Iron Co., and makes a regular business of transporting iron ore from the Marquette range to its own steel and concrete ore-dock at Marquette, has placed an order with Cambria Steel Co. for 400 fifty-ton, all-steel ore-cars to replace worn-out wooden cars, and to increase the carrying capacity of the line. The L. S. & I. besides serving the various Cleveland-Cliffs mines around Negaunee and Ishpeming, carries ore for several other mines and maintains passenger service, competing with the Duluth, South Shore & Atlantic railway. Gradually all the old wooden ore-cars on the several Iron-ore carrying railroads are being replaced by all-steel cars.

As opposed to any contention of the United States government that the Steel Corporation has any kind of a monopoly on Lake Superior iron-ore reserves, or from inference, that there is a lack of competition in the ore business, it is the growing belief and flat declaration of mining officials on the iron ranges that there is altogether too much competition. Within the last five years there have been a number of new arrivals in the ore-mining business at Lake Superior, in addition to which many of the older companies underwent expansion and acquired new holdings. To mention some of the ore-mining operators on the iron ranges, there are besides the Oliver Iron Mining Co., which is the Lake Superior mining department of the Steel Corporation with 30 or 40 great mines; the recently formed Arthur Iron Mining Co., which is the Great Northern or Hill combination of mines in Minnesota, the leases of which were recently relinquished by the Oliver company; the Longyear interests of Minneapolis, which, although a new arrival in the mining business have long been a diamond-drilling contract firm; the Cleveland-Cliffs Iron Co., with a dozen mines on the Marquette Range and two or three elsewhere; Pickands, Mather & Co. with about a dozen mines and developments scattered on the different ranges; Corrigan, McKinney & Co., the Rogers, Brown group of Buffalo; Jones & Laughlin; M. A. Hanna & Co.; and Oglebay, Norton & Co., similarly situated as Picklands, Mather & Co.; the Newport Mining Co. with its two big holdings on the Gogebic Range owned by Ferdinand Schlessinger of Milwaukee; the Republic Iron & Steel Co. with various scattered holdings; the Penn Iron Mining Co. of the Cambria Steel Co; the Loretto Iron Co.; the half dozen mines of the Breitung-Kaufman families; the Tod-Stambaugh Co.; the Inland Steel Co.; the Wickwire Steel Co.; the Davidson Ore Mining Co.; the Zimmerman mine; several locally-owned companies on the Mesabi and Cuyuna Ranges; and a few others. Of this array of mines, perhaps 150 different properties, some only serve to supply ore to their controlling iron or steel companies, such as the Steel Corporation, Jones & Laughlin, etc., but most of the operators sell ore in the open market, and have a more or less regular business, as have the Cleveland-Cliffs Iron Co. or Oglebay, Norton & Co. Due to the activity of some of the newer concerns such as the Breitung-Kaufman companies, or the Great Northern interests, prices have been much cut in late years until several of the old operators claim there is no more profit in the business. Thus during periods of low prices, Jones & Laughlin sometimes curtail production from their own mines, and buy a good portion of their ore in the open market, for the reason that they say they can obtain it cheaply in that manner.

GOLDFIELD, NEVADA

Tests are being conducted on a large scale at the Goldfield Consolidated mill to devise a process to treat the low-grade refractory ores of the district. The equipment for these tests is said to have involved a considerable expenditure, but certain results have been guaranteed. The process involves concentration and oil-flotation, but it is said that it cannot in any way conflict with existing patents of established flotation processes. It has already been shown that $9 ore can be profitably treated, in comparatively small quantities. This value will be reduced in handling a large tonnage. The problem is of vital importance to Goldfield, as there are large quantities of copper-gold ore worth from $6 to $12 per ton in the Atlanta, Mohawk, Red Top, Laguna, and other mines.

A report on the Silver Crown (Stimler) district will be published in the PRESS next week.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

In Professional Paper 87 of the Survey, Charles Will Wright describes the geology and ore deposits of Copper mountain and Kasaan peninsula. This publication covers 110 pages. These are two important copper-bearing areas in southeastern Alaska. The first is a peninsula projecting into Clarence strait from the east side of Prince of Wales island, and the second is a small area which encircles the base of Copper mountain, on the west side of the island, easily accessible to ocean traffic by the upper part of Hetta inlet. Both districts are within the Ketchikan precinct, this town being the recording office.

Juneau

The repaired Central hoist, resumed work on July 13. The break occurred on June 19. The '300' mill lost 10 days, '240' about 24 days, and the '700' and Mexican mills about 21 days each. While stopped they were thoroughly overhauled. At the Ready Bullion mill a concrete foundation is being laid for another 30 stamps. This will make a total of 180 stamps.

According to Charles Hayden, president of the Alaska Gold Mines Co., who has recently been to Juneau, the property is in excellent condition. Cost estimates have been lowered. In June the mill treated 90,790 tons of ore. The daily tonnage will soon be over 5000. During the latter part of August No. 3 unit should be in operation. By September the plant will treat 7500 tons per day. Dividends are possible by July, 1916.

ARIZONA

Producing mines in this state have been valued for taxation purposes at $121,225,834, an increase of $11,000,000. In 1914 they were valued under a specified law, the basis of which was four times net production, plus 1½% of the gross and physical value of the improvement this year. The commissioners fixed the values under the general statute, taking into consideration the earning capacity for the last three years, the selling value of the stock and other matters. The county values are as follows in descending order: Cochise, Gila, Greenlee, Pinal, Yavapai, Mohave, Santa Cruz, and Maricopa. The Copper Queen, in Cochise, leads with a total valuation of $29,357,657.

Cochise County

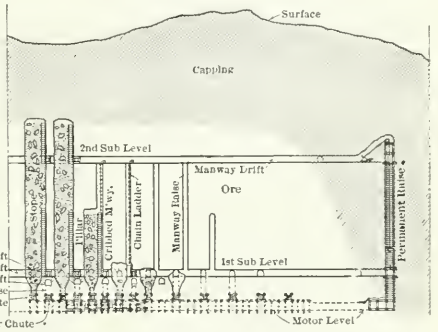
An average of 400 tons of copper, 100 tons of lead, and 100 tons of silicious gold-silver ores is being extracted each day from the Shattuck-Arizona. The lead ore goes to El Paso, the remainder to the C. & A. smelter at Douglas. Over 200,000 tons of $15 gold-silver ore is ready for extraction. Between 300 and 600 ft. is a large quantity of lead ore. A drift at 100 ft. is in 170 ft. in ore averaging 10% copper.

Gila County

The Inspiration Needles company, formed in 1912, controls ground west of the Inspiration and Miami. Shares are now to be sold to obtain money for drilling. Roads are also wanted, four miles having been constructed at $1000 per mile by the company. D. R. Williamson is president.——Mining men in the Gibson district are pleased on account of the county supervisors calling a bond election to re-construct roads, and make new ones into the mining areas.——The Superior & Boston company is to prospect below 800 ft. Sulphide ore found in the lowest level is similar to that at 1300 and 1400 ft. in the Arizona Commercial. Between 600 and 800 ft. in the S. & B. over $600,000 of ore has been extracted from one stope.——Magma Copper Co. shares are being traded in on the New York Curb. They are quoted at about $13. Net earnings in 1915 are estimated to be $750,000, July being $100,000. When the three-compartment shaft is finished in October, full capacity will be attained. Ore reserves in February were estimated at 95,000 tons of 7.6% copper, 8.16 oz. silver, and 56c. gold ore.

Pinal County

Three weeks ago a strike of Mexican miners started at the



CROSS-SECTION, RAY MINE, SHOWING SHRINKAGE STOPES AND PILLARS.

Ray mine. They have returned to work, and will be paid on a sliding scale according to the price of copper.

Yavapai County

Effective July 1, and as long as copper averages 18c. per lb., wages at the United Verde were increased, and will remain so, 25c. per shift.——At the Edith shaft of the United Verde Extension a Nordberg electric hoist, with 250-hp. motor, is to be installed. Underground work is confined to the 1100 and 1400-ft. levels. Regular ore shipments are made to Douglas. When the tramway to the V. T. & S. line is completed, consignments will be made to the Clarkdale smelter. D. Kingdon is in charge pro tem.

CALIFORNIA

Amador County

The Plymouth Consolidated makes the following preliminary report for June: ore treated, 11,000 tons; gold yield, $54,780; operating expenses, $29,940; development charge, $2349; and surplus, $22,491.

Eldorado County

Manhattan, Nevada people, headed by J. McGee, have acquired the property of M. B. Ryan at Frenchtown. A 100-ton crusher is to be erected.——According to B. Evans in the *Placerville Republican*, the Inez-Central or Hearst's mine, one mile north of Amador county, and on the Mother Lode, has a good past record but has been allowed to remain idle for over 30 years. It is full of water and has caved in places, but deserves the attention of companies looking for properties.

Kern County

The Atolia tungsten district is busy. The Atolia company's new mill is nearing completion. Other installations are being put in. Lessees are doing well. The power-line from Randsburg is being extended to Atolia.

At Randsburg the Sunshine mill recovered $3000 from ore from 525 ft. depth.——Seven and a half tons from the Black Hawk, owned by D. A. Blue, yielded $2274. This came from

125 ft. Over 6,000,000 cu. yd. of placer ground is included in this property.

At Woody, the Weringer mine has been opened to 170 ft., and according to A. P. Peake of Butte, Montana, who recently acquired an interest in it, there is probably 100,000 tons of copper sulphide ore in the property. The ore opened averages 4 to 5% metal. Equipment of 500-ft. depth capacity is to be installed.

NEVADA COUNTY

At the Le Duc Mining Co.'s property, between the Empire and Union Hill mines, controlled by Grass Valley and San Francisco people, with B. A. Penhall in charge, four veins have been opened with encouraging prospects. A lava over-burden has made prospecting slow and expensive.

SHASTA COUNTY

(Special Correspondence.)—Considerable prospecting is going on near Heroult, endeavoring to develop a good supply of manganese ore for the smelter. Some good ore has been found. The Noble Electric Steel Co. has applied to the Railroad Commission for permission to lease the Sacramento Valley & Eastern railroad until December 31, 1918. The line extends from Pit, on the Southern Pacific, to Winthrop, near the Bully Hill mines.

Redding, July 18.

SIERRA COUNTY

On July 17 bandits held up the millman and watchman at the Plumbago mine, scraped $3000 of amalgam from the plates and escaped. On July 4 the superintendent, W. B. Pearson, and his foreman, M. McCullough, were robbed.

SISKIYOU COUNTY

(Special Correspondence.)—An auto trip through a good part of this county leaves the impression that, save a few properties, there is little of importance. Farmers are doing well. The El Oro dredge near Yreka is making a satisfactory recovery, as is the boat eight miles away. There are several likely gravel areas that might pay to dredge. The El Oro company is prospecting on Indian creek. A copper mine, being developed by Anderson and others, is shipping 12% ore to the Mammoth smelter. Prospects are good. Freight and treatment costs $13 per ton. The ore yields $40 per ton.

Yreka, July 16.

Good progress is made in erecting the mill at the Victory company's mine at Etna mills.——A good development is reported from the Cub Bear.——Sacramento people have bonded the Miller mine at Indian creek.——A dredge is to be started at Oak Bar on the Klamath river.

SONOMA COUNTY

(Special Correspondence.)—The Culver-Baer quicksilver property of eight claims, and the whole area of 2800 acres, has been acquired by Walker Smith. Mrs. Ida Davis of Angels held an option on the mine. The transaction amounts to $100,000. Ten men are employed, more are to be added. Machinery for large-scale operations is being ordered. Some work has been done each summer in recent years. The mine has had a good past record, but was closed from 1879 to 1901. Cloverdale on the Northwestern Pacific line is the nearest town.

Cloverdale, July 20.

TUOLUMNE COUNTY

During the past 10 months seven sets of lessees (35 men) at the Jumper mine, near Stent, extracted gold worth about $10,000 per month. Only four sets of men made wages or over. A royalty of 25% is paid also $1 per ton for crushing ore.

COLORADO

LAKE COUNTY (LEADVILLE)

Station cutting proceeds at the Penrose pumping shaft. A stoppage of a few hours of one pump, the other working, allows the water to rise quickly, showing the large area to be drained. ——The zinc oxide plant is producing 150 tons of product per month. It contains 70 to 80% zinc, and realizes $100 per ton. Small mines find a profitable market here for their low-grade carbonate ore.——Six cars of over $100 gold ore has been shipped from the Lackawanna Belle. As the snow was late in melting in the Lackawanna district, mining is about four weeks behind.——A large tonnage of carbonate is being shipped from the Hayden shaft on Fryer hill.——In June the Ibex company produced more ore than in any month for five years. The C. & G. lease at the Ibex is mining 200 tons per day.—— The Fortune mine in Big Evan gulch is being re-opened in charge of J. McNeece.

IDAHO

CLEARWATER COUNTY

Transport facilities have retarded development in the county, but ore from several properties is now being sent to smelters at Tacoma and Butte by parcel post. The distance from Stites on the Northern Pacific line to Dixie and other centres is 75 miles by stage. About two tons of ore and concentrate is carried daily at $1.05 per 100 lb. to the smelters. The stage contractors receive 2c. per pound from the post-office, so that the Government is losing money. A highway to cost $100,000 is suggested for the Government. This would aid miners and farmers, and save money for the authorities. The Clearwater districts are busier than ever, according to J. T. Omo. At the South Fork mine at Ten-Mile, Mr. Omo and others have opened a good deal of ore. About $100,000 has been recovered by a 5-stamp mill. A power-plant and 25 stamps are contemplated, costing $25,000. The Buckhorn nearby, has 10 stamps crushing $20 ore. Good profits are being made from a small mill at the Center Star.

CUSTER COUNTY

The Lost Packer mine is working at full capacity, producing 300 tons of high-grade copper ore per day. This is sent to Garfield, Utah. In June 169 railroad cars of ore was shipped. A 50-ton flotation plant is being erected to treat the lower-grade ore. The local smelter is soon to be started. P. J. Boyle is superintendent.

The Lost Packer mine is at an altitude of 5600 ft. It is 110 miles from Mackay on the Oregon Short line. Two high peaks have to be crossed to reach the property. Coke costs $46 per ton. Haulage charges are 2½c. per lb., round trip. Water power is available. The vein is from 6 to 60 in. wide. It is a fissure in mica-schist, dipping 70° west, with a north-south strike. Flat dikes of porphyry and granite-porphyry, 5 to 60 ft. wide, cross the vein. The ore averages 4.5% copper, 0.5 oz. gold, and 26% iron. Ten adits and other underground work total 14,000 ft. A 100-ton hot-blast pyritic smelter has yielded gold worth $300,000, and $150,000 copper, in three campaigns, work being only possible in summer. Ore sent to Salt Lake City totals $50,000. The expense charged against one ton of ore delivered as matte at Mackay is $22. This is the most isolated smelter in the United States.

IDAHO COUNTY

Three mines in the Orogrande district are shipping six tons of ore per month by parcel post.——At Elk City the Mineral Zone and other mines are working. The dredge has been acquired by new people.——Washington, D. C. men have bought the Idaho Champion mill at Dixie. They are putting in 10 new stamps and other plant.

OKANOGAN COUNTY

Near Nighthawk the Caaba mine has been bonded for $40,000 for three years to H. W. Newton, formerly of Republic, and D. H. Jones of Spokane. The present output is 45 tons per day. This to be increased to 75 tons. The Nighthawk 20-stamp mill has been leased.

SHOSHONE COUNTY (COEUR D'ALENE)

The Interstate-Callahan company is to spend $25,000 on improvements. These will include a 200-men dry-house, 20 three-room cottages, 70-room addition to the bunk-house, and in-

creased boarding-house capacity. Shares of this company are now quoted around $20. Before the rise in zinc they were about $4.

The Mining Men's Club of Spokane is to get 200 to 250 representative men to visit the chief points of interest in the Coeur d'Alene about August 15.——It is reported that the Day interests have secured control of the Northport smelter, and that the Hercules mine is to be re-opened. Improvements cost-

INCLINE TRAM, 2½ MILES LONG, FROM STEWART MINE TO LOADING-STATION ON RAILROAD, WHENCE ORE IS HAULED TO THE MILL AT WALLACE, ABOUT 16 MILES.

ing $50,000 are to be made at the mine at Burke.——Helena people have secured a 60-day option on the Idora mine and mill on Sunset peak for $150,000.——The National Copper Co. is examining the Missoula copper mine for the purpose of buying it. The National shaft is being sunk.——A large shoot of copper ore has been opened in the Reindeer-Queen.——The H. E. M. company has purchased plant worth $10,000. The 100-ton mill will be ready in September. Development and plant will have cost $90,000 by then.

MICHIGAN

At the new Isle Royale mill the second stamp started last week. A third will be ready in a few weeks. The daily tonnage is now 1200.——The New Arcadian shaft is down nearly 1000 ft.——About 10 drills are working in the South Lake. Ore is to be sent to the Franklin mill.——At the Franklin 18 drills are working, mostly in Allouez conglomerate. When the electric haulage plant is installed, shipments will be from 1000 to 1200 tons per day.——The North Lake shaft is being sunk to 800 ft. at the rate of 50 ft. per month.——The Hancock has 30 machines at work, but the output is only 300 tons daily.——Prominent copper men have been visiting the White Pine district.

MISSOURI

Jasper County

Calculating that the Joplin district production was reduced by 4000 tons per week owing to the strike, the value being $385,000, the cost of this would be $200,000, of which labor would get $102,000. So the men were losers by this amount. All mines are again operating. The attempt at unionizing the men apparently failed.

Production of the Missouri-Kansas-Oklahoma district last week was 2502 tons blende, 175 tons calamine, and 662 tons lead, averaging $96.04, $53.54, and $59.79 per ton respectively. The total value was $289,170.

It is reported that a 700-ton mill is to be erected by the U. S. Smelting company at the Ravenswood lease of the Cornell land, three miles southwest of Sarcoxie. The greatest speed will be made in construction.

At the Missouri Lead & Zinc Co.'s land a 10-in 4-stage Texas pump has unwatered a number of shafts to 95 ft. depth. Many men are applying for leases at the drained area.

A 300-ton mill is to be constructed by W. Squires on a lease of the Cosgrove land, Duenweg.

A thorough geological investigation has been made of the Saginaw Mining & Leasing Co.'s lease of 746 acres of the Saginaw Investment Co.'s land at Saginaw. The object was to see whether they would buy the lease for $150,000. Good developments have been made.——A 150-ton mill is being erected on the Bert Flournoy land, near Aurora. Ore is found at 90 ft., continuing to 160 feet.

MONTANA

Cascade County

The Queen and Galt companies' properties at Neihart are being examined by C. J. Kelley and Reno H. Sales for the Anaconda company. The mines produce low-grade lead-silver-zinc ore. Treatment has been a difficulty, but flotation is expected to solve the problem.

Lewis and Clark County

A comprehensive map, 42 by 62 in., of the mining districts tributary to Helena, has been prepared by The Engineering Corporation of Helena. With it is a printed index of 32 pages giving the number of each claim, location by section and township, and name of present owners together with their post-office address. The price is $5 and $6 respectively for the two styles of maps with index. A great revival of mining is taking place in the district, which has produced a great deal of gold, silver, and lead. Zinc ore also occurs in commercial quantities.

Silverbow County

The county assessor values property of all descriptions at $39,516,795, plus $3,000,000 for railroads.

The Butte & Milwaukee property, controlled by the Butte & Superior company, is to be developed. By a cross-cut from the Black Rock claim, it has been opened to 1200 ft. A new hoist will be ordered for the Colonel Sellers shaft. In the Black Rock a station is being cut at 1700 ft. The shaft is progressing at 75 ft. per month. It is in zinc ore and is hard to break. The daily tonnage has been somewhat lower than in April, 1300 to 1400 against 1700 tons.

NEVADA

Esmeralda County

Thirty miles northwest of Millers is the Orizaba mine in charge of L. L. Patrick, from which 30 tons of ore is to be shipped. Past shipments totaled $50,000. Development is encouraging, and a mill is contemplated. The Diamondfield Black Butte Reorganized Mining Co. of Goldfield, controls the property.

F. A. Wheeler and C. W. Watson, lessees at the Cottonwood Canyon Mines Co.'s property at Silver Crows, formerly Stimler, 50 miles west of Goldfield, state that a mill may be erected after a suitable process is devised.

At the meeting of the Jumbo Extension company at Phoenix, Arizona, on July 19, Charles S. Sprague was elected president and general manager. This is a vindication of his past work, over which there was considerable controversy.

Nye County

Five companies and lessees at Tonopah last week produced 10,307 tons of ore worth $211,486.——Some June outputs are as follows:

Mine.	Tons.	Bullion.	Profit.
Belmont	14,693	267,830	$84,234
Jim Butler	4,680	.....	34,777
Tonopah	12,170	248,525	83,635

In the Extension new stopes are being opened at 1260 ft. The stope at 1170 ft. is 20 ft. wide, against 35 ft. previously.

——The Midway shaft is down 1300 ft. Lessees are opening new ore of good grade.——The diamond-drill at the Umatilla is down 1390 ft.——The West End mill treated 1071 tons last week.

STOREY COUNTY

Rapid progress is being made in the mines at the north end of the Comstock, according to W. W. Turney of San Francisco. At 2700 ft. and other points, work is nearing the time when the ventilation and drainage will allow prospecting to proceed to advantage. In the Ophir a good quartz lode has been followed from 1800 to 2500 ft. Work under way in the Mexican, Union, and Sierra Nevada is of great importance. In the first named, output last week was 135 tons of $8.36 ore, the Patton cross-cut has opened a vein at 2500 ft., west of the stope between that level and 2300 ft. which yielded nearly $1,000,000. In the Union at one point there is 9 ft. of quartz assaying up to $40 per ton. It is estimated that the east and Comstock veins will junction at 2700 ft. In the Central drift the Ophir continues to get favorable results. At 2700 ft. the Pumping Association is repairing the south drift from the Union-Mexican winze.

WHITE PINE COUNTY

The Princess Copper Co., composed of Salt Lake City men, is to start work at its property near the Nevada Consolidated. Some development has already been done, and ore shipped. C. W. Freed is president.

NEW MEXICO

In Bulletin 1 of the New Mexico School of Mines at Socorro, the mineral resources of this state are discussed by Fayette A. Jones, director of the institution. With a map it covers 77 pages. A catalogue of minerals gives 224 names, and the districts in which they occur. The mineral production of the state is expected to be $20,000,000 during 1915. The industry rivals the combined industries of cattle, sheep, agriculture, and horticulture. The mines of New Mexico employ more men than any other single industry, save farming. A historical summary of mining in the state is given, followed by general geology and distribution of minerals by districts and counties. The publication is a valuable résumé of the present situation of the industry in New Mexico.

LINCOLN COUNTY

At White Oaks last week the Wild Cat company's Wilson, Old Abe, Harrison, and Homestake gold mines were acquired by a company including W. M. McDonald, T. N. Stanton, and R. Wightman.

The Old Abe has produced over $1,000,000 to 1500 ft. depth, and the Homestake a large amount from 1000 to 1400 ft. A good deal of ore exists in the latter.

LUNA COUNTY

Los Angeles, California, and other men have bought the Grand Central mine in the Lake Valley district. This is a zinc-lead property. Enough ore has been opened to justify a 300-ton mill.

SOCORRO COUNTY

The Mogollon district is prosperous.——Good ore has been opened in the Pacific mine.——A dividend amounting to $50,000 is to be paid by the Socorro Mines Co., the first for 2½ years.——The Ernestine company has paid 2%, the first for two years. This company has been spending a good deal on development and equipment.

SOUTH DAKOTA

In the Palace of Agriculture at the Panama-Pacific Exposition the mines of this state are represented by three cases of specimens and pamphlets. The Black Hills region is essentially a gold producer, 95% of over $7,500,000 mineral production in a year being gold. The silver yield is about 100,000 oz., and sand and gravel over 1,000,000 tons. The exhibits include samples of gold ore from the Homestake, Wasp No. 2, Golden Reward, Hidden Fortune, Heidelberg, Treasure, Imperial, Ragged Top, Phoenix, Echo, Hidden Treasure, Bismarck, Two John, and Hailstorm. There are also displayed spodumene, cassiterite, Nigger Hill tin, sandstone, limestone, and sand-lime brick.

LAWRENCE COUNTY

The North Homestake mine, in the Maitland district, is to be re-opened. During a long shut-down an electric pump kept water at 200 ft. The shaft is to be unwatered.——Work has been resumed at the Hidden Treasure's 200-ft. level. The hoist, etc., was overhauled.——The Monarch has been leased, and pumping is under way.——The Homestake Extension is to be sampled as soon as the shaft is unwatered.

PENNINGTON COUNTY

According to C. H. Kamman, his company's Cowboy mine near Hill City contains tin worth over $40,000. The Mohawk mine will supply the 25 to 50-ton mill to be erected. This will be constructed mostly from the old Harney Peak tin mill.——The tin plant west of Hill City is busy, and tin bars are reduced from the concentrate.

TEXAS

EL PASO COUNTY

The A. S. & R. smelter at El Paso is receiving more ore than it can handle, so some contracts are being treated at the smelter at Hayden, Arizona.

UTAH

JUAB COUNTY

On July 16 the Iron Blossom company paid 5c. per share. The quarterly dividend is to be reduced to this amount, equal to $50,000, from the usual 10c., or $100,000. Present earnings will allow of the old rate before long.——On August 2 the Chief Consolidated will pay a 5% dividend.

An old tailing dump of 4000 to 5000 tons at the McIntyre ranch, southwest of Silver City, is to be shipped to the Garfield smelter.

SALT LAKE COUNTY

According to Charles Hayden, the Utah Copper Co. is operating now at full capacity for the first time. This means that it is in position to take full advantage of the present price of copper, and consequently is making large profits. Never before have operating conditions been so favorable for the property. Hitherto any increase in milling capacity would have been based upon the ability to increase the rapidity of stripping, but the stripping is now so far advanced that the mine can increase tonnage as rapidly as any increase in milling capacity can ever be constructed. Some idea of what the mine is doing may be gained from the statement that one day last week 28,000 tons of ore was treated in mills whose capacity was originally figured at 21,000 tons per day. It is thought that 30,000 tons per day is a possibility.

The Little Cottonwood district companies are very busy. Good developments may be expected.——In the Alta Consolidated about 8 in. of high-grade ore is being opened.——In the Columbus Extension the southwest drift is in softer limestone well mineralized.——At the Emma copper mine 4 to 6 in. of carbonate ore has been cut. Five to seven feet of silver-lead ore has since been cut.——At the quartzite-limestone contact in the Sells, 8 in. of good sulphide ore is being driven on.——The Wasatch continues to ship ore.——The Cardiff company reports $109,576 cash and ore sold on July 1.

At Big Cottonwood, the Alta Tunnel company's adit is in 1313 ft. More water has been encountered. Engineers of Salt Lake City have examined the property with the idea of using the water, estimating from 1,300,000 to 1,900,000 gal. per day.

SUMMIT COUNTY

Plans for a 500-ton mill, employing tables and oil flotation, to treat the dump of about 400,000 tons of zinc-lead-silver tailing acquired from the Grasselli Chemical Co., by the

Broadwater Mills Co. at Park City, are being prepared by Kirk & Leavell of Salt Lake City.——The 250-ton mill to treat 800,000 tons of tailing at Atkinson, seven miles north of Park City, started on July 16. Kirk & Leavell also planned this, for the Big Four Exploration company.

WASHINGTON COUNTY

Several mining men predict that Goldstrike promises to be an important producer. Results at the Goldstrike Con., Bonanza, Primers, La Vors, Bnll Valley, and Hassayampa are decidedly good. In the first named 30 in. of rich ore is being opened.

WEBER COUNTY

Abont 200 men are to be employed at the Promontory Point zinc mine, controlled by the Lakeview Mining Co., Lorenzo Farr, president. The company has leased its Carbonate Hill ground and No. 1 claim, at a royalty of $9 per ton shipped. Shipments have been made for some time. Auto-trncks are to be used to haul ore to Saline, three miles.

CANADA

BRITISH COLUMBIA

A smelting contract for zinc ore from the Lucky Jim mine at Zincton has been arranged with the Granby Mining & Smelting Co., at Neodesha, Kansas. Crude ore will be shipped first, concentrate from the Ivanhoe mill at Sandon later on. ——The Slocan Star mine and mill is employing 65 men. The vein was recently cut at 900 ft. Development is to start at 1000 ft. The daily output of the mill is 14 tons of zinc and 4 tons of lead concentrate.——The Surprise mine is shipping 300 tons of zinc concentrate, and some ore, to the Empire Zinc Co., New Jersey.——At the Rambler-Cariboo are 50 to 60 men. Lead concentrate is sent to the Trail smelter. Zinc product is being stored until a new contract is made.——At the Cork mine, between Kaslo and Zincton, 35 to 40 men are mining lead ore.——A good profit is made at the Utica with over 30 men.——In the Noble Five adit, a vein was cut at a depth of more than 1500 ft.——Fifty men are to be employed at the Ruth at Sandon.——Oil flotation at the Hewitt, Silverton, is producing zinc and lead concentrates. About 500 men are working.

ONTARIO

The June report of the Nipissing includes the following information: high-grade mill treated 180 tons; low-grade mill, 7670 tons; total net production, $186,791; and refinery shipments, company and custom, 764,559 oz. Two machines drilled surface veins exposed by hydraulic prospecting. Several produced some low-grade mill ore. Best results were obtained in the Keewatin formation. The best was 50 ft. long, 1 to 2 in. wide, assaying 2000 oz. per ton. The hydraulic plant is operating on conglomerate and slate formation. On No. 4 level, snaft 73, two branch veins opened well. One is 2 in. wide, assaying 2000 oz. Other interesting development was done.

During June the Dome mill treated 27,200 tons of ore averaging $4.45 per ton, a record.

The Alexo nickel mine shipped 989 tons of ore to the smelter at Coniston in June.

KOREA

The Seoul Mining Co., operating the Suan concession in Whang Hai province, reports the following for June, at the Suan mill:

Ore treated, tons	6,350
Mill operating, days	27.2
Bullion recovered	$42,300
Concentrates	26,500
Total	$68,800
Operating expense	$27,500
Net earnings	$41,300

Construction of the new 400-ton capacity mill at the Tul Mi Chung mine on the concession is progressing satisfactorily. It will commence operating in August.

PERSONAL

JOHN B. FARISH is here.

R. A. F. PENROSE is at Denver.

GEORGE E. FARISH is in New Mexico.

H. C. BELLINGER is going again to Chile.

HAROLD A. LINKE is visiting the Exposition.

J. DAWSON HAWKINS is here from Colorado Springs.

R. A. KINZIE was at Salt Lake City during the week.

H. VINCENT WALLACE has left Mexico and is now in New York.

E. P. MATHEWSON is expected in San Francisco on September 14.

THORVALD J. ANDERSON has returned to Boston from Valdez, Alaska.

F. LYNWOOD GARRISON is going to Arizona and will come later to San Francisco.

J. S. DILLER is at Drakesbad, Plumas county, studying the eruption of Mt. Lassen.

H. L. SULMAN has been elected president of the Mining & Metallurgical Clnb, in London.

C. J. KELLEY and RENO H. SALES are examining mines at Neihart for the Anaconda company.

H. R. PLATE passed through San Francisco on his return from British Columbia to New York.

WILLIAM B. PHILLIPS, of Austin, Texas, has been selected as president of the Colorado School of Mines.

GILBERT L. GUTHRIE, of the Butters company, was here from Russia and has returned to Atchison, Kansas.

ARTHUR C. TERRILL has been appointed head of the department of mining engineering in the University of Kansas.

E. C. TEMPLETON sailed on July 17 for Yokohama on his way to Siberia, to serve as geologist to the Ridder mine, in the Altai.

F. L. BOSQUI, in migrating from Johannesburg to London, has not resigned his appointment as consulting metallurgist to the Rand Mines, Ltd.

G. S. ROGERS, of the U. S. Geological Survey, is expected shortly to continue investigations in the water and oil problems of the San Joaquin valley.

H. M. DRAKE, son of Francis Drake, has been killed fighting as a second lieutenant with the British army in northern France. He had served previonsly in the Boer war.

Schools and Societies

The CANADIAN MINING INSTITUTE opened its meeting at Rossland, B. C., on July 15. Many well-known men attended.

The business sessions of the snmmer meetings of the GEOLOGICAL SOCIETY OF AMERICA are to be held as planned at the University of California and Leland Stanford, Jr., University, August 3-5, 1915, in affiliation with the American Association for the advancement of Science.

The AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will commence a meeting at San Francisco on August 2. This will be the first meeting of this organization west of the Rocky Mountains. The society has over 9000 members, representing all fields of scientific research. Over 20 other societies organized in various branches of science will also convene at the same time, or will participate in joint meetings during the week. The branches of science included in the series of meetings are: astronomy, mathematics, physics, geology, palaeontology, seismology, zoology, genetics, botany, psychology, anthropology, archaeology, education, and agriculture.

THE MARKET PLACE

Weekly Summary of Metal Prices and Notes on the Markets.

Metal Prices

San Francisco, July 22.

Antimony	35 —35¾
Electrolytic copper	20½—20¾
Pig lead	6.00— 6.95
Quicksilver (per flask)	$95
Spelter	24 —24¼
Tin	39 —40½
Zinc-dust, 100-kg. zinc-lined cases	38

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, July 22.—The copper market is lifeless; in lead, re-sale lots are active; spelter is quiet.

COPPER

Prices of electrolytic in New York, in cents per pound.

Exports of copper during the week ended July 3 totaled 10,579,720 lb., valued at $1,900,142. France took 3,265,477; England and Scotland, 3,373,410; Italy, 1,608,046; Russia, 1,120,381; Sweden, 672,727; Holland, 287,772; and Spain, 237,355 lb. Imports of all kinds amounted to 6,333,249 lb., worth $743,759. Chile sent 2,581,331; Peru, 1,860,311; and Canada, 1,826,194 pounds.

Stocks in Europe and afloat thereto from Chile and Australia on June 30 totaled 38,041 tons

The Amalgamated Copper Co. has declared a dividend of $1 per share, an increase of 50c. Arrangements have been made for the distribution of the company's assets. This will commence on August 30. Each holder of Amalgamated will receive share for share in the new Anaconda stock, par value $50, representing two shares of old Anaconda. Also a cash distribution which is estimated at about $3 per share.

Braden, Chile, produced 2,542,000 lb. in June. This was from 91,000 tons of 2.1% ore, with a recovery of 77.21%. The estimated cost is 8½c. per lb. The half-year's total is 15,238,000, an increase of 2,787,000 pounds.

SILVER

June	56.43	49 03	Dec	49.27	....

Notwithstanding an occasional burst into activity, the market has subsided into a condition of inertia, from which there is just now nothing in sight to suggest an improvement. Both India and China seem to be waiting on each other to determine at what figure to intervene, and this indecision naturally is against the interests of sellers. It might have been conjectured that the recent fall in price was in consequence of the large arrival of Mexican silver in London by a United States steamer at the end of June. Such an assumption, however, is incorrect, for, by a circumstance fortunate for the seller, a special demand, unconnected with India or China, happened to arrive exactly at the time of realization, and the bulk of this abnormal supply was absorbed without any pressure upon the market at all, according to Samuel Montagu & Co. The state of affairs in Mexico precludes the idea that further Mexican supplies can be anticipated for some time to come. On July 9 about 350,000 oz. left San Francisco for China. The Beaver company, Cobalt, reports a stock of about 360,000 ounces.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending			
June 23	95.00	July 7	95.00

Zinc-ore buyers in Utah are now bidding for carbonate ore as low as 30% metal.

Zinc mines in New Jersey in 1914 produced 148,506,500 lb. from 529,443 tons of ore. This was an increase of about 4,200,000 pounds.

The Interstate-Callahan zinc mine will pay $2 per share, $920,000, on August 10. This makes $1,160,000 for the year.

TIN

Prices in New York, in cents per pound.

On July 22 tin was firm at 36.75 to 37.25c. per pound.

Eastern Metal Market

New York, July 16.

The entire market in metals has been dull and uninteresting since the last report. Meanwhile the consumption for war purposes is going on at full tilt, and new factories are preparing for the manufacture of munitions. The activity of New England, the centre of the metal-working industry, is actually feverish, and the only fly in the ointment is labor trouble. This is not yet serious, but the indications are threatening at Bridgeport, Connecticut. In that city it is stated that the big work in the munition line at present is supplying the brass cases, one of which goes with each shrapnel shell. It is understood that the American Can Co. has taken a contract running into the millions for work of this character.

The steel business continues to flourish, as evidenced by the fact that the U. S. Steel Corporation's unfilled orders increased 413,000 tons in June. The Corporation is now working about 90% of its ingot capacity. It is buying large tonnages of billets from independent mills, and activity to the end of the year seems assured. Additional furnaces for making iron and steel have been started both East and West. Advances in iron and steel quotations are general. High-speed steel, now in much demand, is scarce and going to unheard of levels because of the scarcity of tungsten and chromium, both of which are supplied chiefly by foreign makers.

COPPER

Continued dullness has brought out concessions in prices, especially on the part of second-hands, although an easier tendency on the part of producers has developed also. Producers would consider offers of less than 20c., 30 days, delivered, for electrolytic. Second-hands offered the metal July 13 at 19.50c., and probably would have taken less. On July 15 sales were made at 19.12½ to 19.25c. full terms. The exact level of the market is difficult to place; in fact, there may be said to be no exact level in the absence of important transactions. On no side does there appear to be any disposition to take much copper. High-grade Lake has softened a little and 22c. is quoted, although a Bridgeport shell-manufacturer complains of the difficulty he encounters in getting it. An old New Haven manufacturer of hardware says that for the first time in his experience he has advanced the prices of his products in the face of a dull market for this material. Incidentally he remarked that with metal-prices where they are, he buys no further ahead than is absolutely necessary. Though prices are easier, the makers of brass and copper products, such as rods, sheets, tubes, wire, etc., are not issuing list-prices and all quotations are subject to immediate acceptance. The demand for brass, and its consumption in New England, continues on an enormous scale, which is to be expected with the ammunition plants working night and day. Members of the trade point out that great as consumption may be, halts in buying raw material are to be expected. Deliveries against contracts are good. A curious circumstance is related by a manufacturer of rolled-sheet copper and certain products. Apparently as a result of the prohibition wave that is sweeping over sections of the country he has not received, for months, even one order for brewers' kettles. Until lately they were a source of lucrative business. It happens, however, that the loss of this business has been more than balanced by an excellent demand from new sugar-plants in Cuba, while locomotive fire-box plates have been in excellent demand, largely for export. The circumstance, while not of great importance, illustrates how the alignments of trade adjust themselves. The exports this month (to July 17) total only 6288 tons. In the first 6 months of this year the exports were 136,527 tons, against 219,494 tons in the same period last year.

LEAD

The market has weakened and has shown much uncertainty. Certain dealers are of the opinion that higher prices may be looked for soon, and have shown their faith by buying lots at figures below the quotations of the A. S. & R. Co., namely, at 5.75c. New York. In the past few days there have been extremely large deliveries against the heavy purchasing in the excitement of a few weeks ago. At this writing the market is very dull, and is lower. The New York quotation July 15 was down to 5.60c. It is pointed out that a sudden change may be expected, inasmuch as the relation between supply and demand is closer than usual. Foreign buying has been lighter, as might be expected when London is below New York parity. The exports, to July 17, amounted to 1144 tons. Italian interests have made inquiry recently and their failure to culminate in orders leads to the belief that the demand was satisfied with Spanish lead. The unwillingness of England to permit the exportation from her shores of any of the metals is favorably regarded, as it may force other European nations to replenish their stocks direct from the United States.

ZINC

The demand has been irregular, and while prices were about to touch 23c., July 8, they soon weakened under a lessening demand and freer offerings. By July 14 prompt deliveries were quoted at 22c., and even this figure might have been shaded. London continued steady at £100 per ton for some days, but on July 15 dropped to £96. August spelter is stronger, relatively, than July, for the reason that most consumers are supplied for the first month and not for the latter. There were export inquiries and buying about a week ago, when quotations ranged from 22.50 to 23c. for prompt, 22c. for August, and 20c. for the last quarter of the year. On July 16, the quotation for prompt was down to 21.25c. Sales of prime western have been made in the past few days for delivery into next May. Brass-mill grades continue to command fancy prices, and for Bertha and Horsehead, made by the New Jersey Zinc Co., 40c. has been offered. The miners' strike in the Joplin district, which, strangely enough, seemed to have but little effect on the situation, was ended early this week. It is understood that no immediate concessions were granted by the employers. The exports, July 1 to 17, totaled 2073 tons.

TIN

For several days the market has been dull and uninteresting. The situation is due to consumers being well covered, the liberal supply and prospective arrivals, while speculation is at low ebb. The arrivals up to July 17 totaled 2639 tons and there was afloat on that day 5710 tons. Quotations have declined, until 38.90c. was reached July 9. That of July 12 was 38.62½c., that of July 13, 38.12½c. and of July 14, 37.75c. According to Metal Exchange figures the stock of unsold Banca tin stored in Holland, June 30 was 1146 tons, against 2861 tons, January 31.

ANTIMONY

Recent arrivals of Chinese and Japanese antimony and subsequent freer offerings have given an easier tone to the market, and 36c. has been shaded, although the general range of quotations is unchanged at 36 to 37c., New York. The market has been quiet.

ALUMINUM

Small lots of aluminum continue to command 31 to 33c. Sheets are quoted at 34 to 36c. per pound.

Oil production of the United States in 1914 totaled 290,312,535 bbl., a large increase. The average price was 80.6c. per barrel. California produced 99,775,327 bbl., at 46.7c. per barrel.

MINING DECISIONS

OIL AND GAS LEASE—ASSIGNMENT—WARRANTY

An oil and gas lease is a chattel real. But in case of an assignment by the lessee of all his "right, title and interest" therein, where the assignee has knowledge of a prior existing lease, the general rule applicable to sales of personalty that the act of selling is in itself an affirmation by the vendor that he is the owner, out of which arises an implied warranty of title, does not obtain.

Tupeker *v.* Deaner (Oklahoma), 148 Pacific, 853. May 11, 1915.

SUBSIDENCE OF SURFACE—MEASURE OF DAMAGES

Where, by reason of coal mining beneath certain land, the surface was caused to subside for lack of sufficient props to support the roof of the mine, the lessee who was operating the mine and not the mine owner was responsible to the owner of the surface for damages caused by the subsidence. The measure of these damages was the difference in value of the land before and after the subsidence.

Jackson Hill Coal & Coke Co. *v.* Bales (Indiana), 108 Northeastern, 962. May 28, 1915.

MINING PARTNERSHIP—DISTINGUISHED

Where a party is employed by another to look after certain mining claims and sell the same when opportunity afforded, his compensation to be one-half of the net proceeds after deducting expenses of sale and reimbursing himself for any personal advances theretofore made, his relationship is purely one of trust and he is not in any sense a 'mining partner' nor can he be sued for wages alleged to be due a watchman employed by his principals.

Peterson *v.* Beggs (California), 148 Pacific, 541. March 15, 1915.

EXTRALATERAL RIGHTS—INTERSECTION OF VEINS

In a suit brought for injunction to restrain trespass and damages for taking of ore at the intersection of two veins on their dip, the trial court found that the owner of the senior claim was within his extralateral rights on a vein apexing within his own claim. It follows, as a well established rule of law that he was entitled, by reason of his senior location, to the ore lying within the intersection of the two veins. Injunction denied the junior claimant.

Esselstyn *v.* U. S. Gold Corporation (Colorado), 149 Pacific, 93. June 7, 1915.

DAMAGES FOR TRESPASS—EVIDENCE

A judgment for the plaintiff in an action to recover the value of ore alleged to have been taken by defendant from two veins apexing in plaintiff's mining claim, but extending on their dip beyond its vertical side-lines beneath the surface of defendant's adjoining claim, rendered under a stipulation that only the issue of title and right to possession of the veins and ores in controversy should be tried, leaving the question of damages to be later disposed of, was construed to relate only to the title and right to possession of the ore in the two veins which were in issue in the first case. The defendant was entitled, on the subsequent trial of the issue of damages, to show that a portion of the ore taken from its claim within such claims was from other veins than those involved in the first suit. Hence the evidence offered by defendant to prove this point was material in that it might lessen the damages plaintiff was entitled to recover and should be submitted to the jury.

New Machines and Devices

Information based on letters and catalogues from manufacturers.

Cleaning Hollow Drill-Steel

With the advent of the Jackhamer and similar machines using hollow drill-steel, a new trouble developed which has been the cause of considerable annoyance and added expense. The hole in the hollow steel often becomes plugged with particles of cuttings and dirt. As soon as a 'steel' is clogged in this way it is useless until cleaned out, as the function of the hole in the steel is to permit passage of air to keep the bottom of the drill-hole clear; in water-drills, like the Leyner, to allow a thin stream of water to pass through by air pressure and wash out the cuttings. At times, however, as experience shows, the dirt will get into the steel and plug up.

PNEUMATIC DRILL FOR CLEANING HOLLOW DRILL-STEEL.

Perhaps the most frequent method heretofore employed, particularly when only a few drills are used, has been to heat the steel, after which it is an easy enough matter to remove the obstruction with a long thin wire, or by air pressure through a nozzle. As can readily be seen this method takes some time and labor. Also care must be taken when heating so as not to destroy the temper of the steel.

Another method of abstracting the dirt, which is far more economical and rapid, is to use a light pneumatic drill. The plugged steel is first laid out before re-sharpening the bits, and a jet of air is applied through a nozzle. In many cases this air pressure is sufficient to clean the steel, but if the obstruction cannot be removed with the air-jet, the pneumatic drill is employed. With the $\frac{7}{8}$-in. hexagon hollow Jackhamer steel, $\frac{1}{4}$-in. wire is used; with steel having a larger diameter hole, such as the $1\frac{1}{4}$-in. or $1\frac{1}{4}$-in. steel used with the No. 18 Leyner-Ingersoll machines, a correspondingly heavier wire can be applied. If the drill-steel is plugged about three feet from the shank end, a $3\frac{1}{2}$-ft. wire is long enough. If, however, the obstruction is, say, about 3 or 4 in. in from the shank end, a wire from 6 to 8 ft. long is required, working from the bit end of the steel. Of course the time required to remove the dirt depends on its depth and hardness. It usually takes from one to five minutes. Compared with the method described above, this represents a large saving in time, according to Coly M. Olson.

The pneumatic drill employed for this service is manufactured by the Ingersoll-Rand Co. and is known as the No. 44 Little David non-reversible drill. It weighs only 10 lb. It has a pistol-grip handle, is $15\frac{1}{2}$ in. overall, with a cylinder bore of $1\frac{1}{4}$ in. and a $\frac{3}{4}$ in. stroke. Air consumption is about 17 cu. ft. of free air per minute, at 90 lb. pressure. It is also equipped with a speed regulator by means of which any speed from 1500 to 3000 r.p.m. may be obtained. This drill can also be used for drilling up to $\frac{3}{8}$ in. diameter holes in metal. It has a simple revolving motor, is well-balanced and entirely free from vibration, so the operator has no trouble in handling it. It is admirably suited for the purpose above mentioned.

Electric Incline Railway

An incline railway, which might suit some mining companies, has recently been installed at Hamilton, Ontario, by the Hamilton Mountain Park Co., Ltd. It is used for transporting passengers, freight, automobiles, trolley-cars, teams, etc., up the mountain, the difference in elevation being 325 ft. The machinery was formerly steam driven. The electric hoist equipment, containing many novel features and automatic safety-devices, was supplied by the Canadian General Electric Co., Ltd., a connection of the General Electric Co. of Schnectady, New York. A double fixed-drum, double-geared electric incline hoist, built by the Lidgerwood Mfg. Co., New Lork, operates two 15-ton platform cars in balance, on an incline 800 ft. long, with a grade of 40.27%. The average load is 10 tons. Each trip takes 1.5 minutes. Attached to each car are

HAMILTON MOUNTAIN PARK ELECTRIC HOIST, SHOWING BOTH MOTORS AND GEARED CONNECTORS TO DRUMS, ALSO SOLENOID-BRAKES, CLUTCH, AND FLYBALL SPEED LIMITING DEVICE.

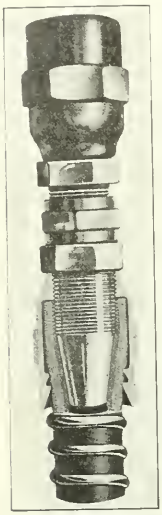
two $1\frac{5}{8}$-in. diameter ropes, one for hauling, the other for safety. The average rope-speed is 585 ft. per minute. Sheave arrangement, operation of hoist and safety ropes, safety appliances, automatic overwinding mechanism, overspeeding device, shaft, drums, gears, electric equipment, including the Electric Storage Battery Co.'s of Philadelphia battery, load-demand, etc., are all described in the paper sent us by the General Electric Company.

Motors for Flotation Agitation

Power consumption is an important item in flotation processes in which mechanical agitation is used to produce the froth. A direct-connected agitator has been devised by the engineers of the Westinghouse Electric & Manufacturing and the Utah Copper companies. The machine has given such good service that over 500 are now in use. The design has since been followed by other manufacturers. The agitator paddles are mounted on a short section of shaft fitted with a cup-shaped bushing, threaded on the inside. The shaft of the vertical-suspended motor is virtually a continuation of the agitator-shaft, and is threaded on the outside, the two being screwed together. The motor is 10-hp., 440-volt, 3-phase, 60-cycle, 12-pole running at 575 r.p.m. full-load speed. The special features of this motor are the heavy thrust-bearing at the top, and the heavy guide-bearing at the bottom. There is no step-bearing in the agitator cell, and the entire weight of the revolving part of the motor, the motor-shaft, the flange-coupling, the paddles, and the paddle-shafts, is suspended from the thrust-bearing in the top of the motor. The heavy guide-

bearing at the bottom of the motor-housing is made with large bearing-surfaces and heavy webs holding it to the bearing-bracket, so that it will absorb any lateral thrusts which might develop, due to a slightly unbalanced paddle revolving at such a high speed.

New Hose Coupling

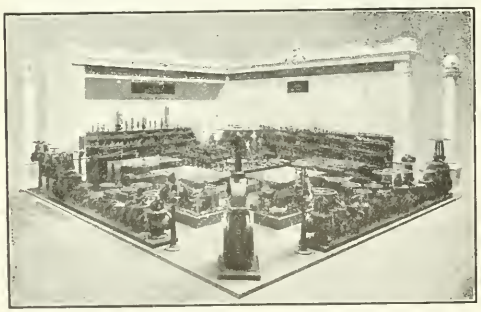


NEW HOSE COUPLING.

In its 'National' hose coupling the NATIONAL HOSE COUPLING Co., Peoples Gas building, Chicago, claims that for railway, shop, shop air-tool use, foundries, rock-drills in mines and quarries, hose connection to water-pipes, packing house steam hose connections, and everywhere that hose meets hard service nothing is superior to its hose coupling, as illustrated. No special tools are required for its use. The malleable iron hose socket is sufficiently corrugated on the inside to provide a positive grip when the hose is expanded, and simply screwing the steel taper expander into the socket forces the hose outward and into position. The hose readily enters the socket and may be cut and re-coupled as often as required in the same way. The edge of the socket and end of expander are smoothly rounded to prevent injury to the hose. The only pressure on the hose is from the inside. A price-list is given.

Valves, Lubricators, and Fittings at the Exposition

In the Palace of Machinery at the Exposition at San Francisco, the Lunkenheimer Co. of Cincinnati, Ohio, has an artistic display of its engineering appliances. In great variety are displayed bronze, iron, puddled semi-steel and cast-steel globe, angle, cross, check, gate, balanced-throttle, and non-



PIPE-FITTINGS AT THE EXPOSITION.

return safety boiler stop-valves; also bronze and iron pop safety, relief, and blow-off valves; water-columns and gauges; whistles, ground key-work, injectors and ejectors; bronze fittings and unions; cylinder lubricators, oiling devices, oil and grease-cups; automobile and motor-boat specialties, and many other fittings of high-grade quality.

In *Graphite* for July, the Joseph Dixon Crucible Co., New Jersey, describes a deep well pump at Bowie, Texas. The delivery from 500 ft. is 160 gal. per min. Main bearings have a pressure of 25,000 lb. Cylinder oil and flake graphite are used on bearings and gear.

Commercial Paragraphs

In seccion U-cuarta edicion, CHALMERS & WILLIAMS of Chicago Heights have described the Symons-disc-crusher in Spanish.

The DU PONT NITRATE Co., Wilmington, Delaware, is installing a Chalmers & Williams, Chicago, 24-in. and a 48-in. Symons disc-crusher at the nitrate works in Chile.

Truck catalogue F-3e of the THOMAS B. JEFFREY Co., Kenosha, Wisconsin, describes the "truck that solves all the problems in road transportation," the 'Jeffrey Quad.'

Ball-tread tractors made by the YUBA CONSTRUCTION Co., Marysville, California, are exhibited in the Palace of Agriculture at the Exposition. Those shown are No. 12 and 18 sizes. The gear is shown in a separate exhibit.

At a meeting of the directors of the AMERICAN LOCOMOTIVE Co., New York, held on July 14, W. Spencer Robertson was appointed secretary of the company to fill the vacancy caused by the resignation of C. B. Denny, effective this date.

The BURD HIGH COMPRESSION RING Co., Rockford, Illinois, reports that it is beginning the installation of machinery in an additional new factory building, containing 30,000 sq. ft. of floor-space. Waiting and new contracts have rendered necessary this increase in plant.

The VULCAN ENGINEERING SALES Co., Chicago, general agent for the Hanna Engineering Works, Mumford Molding Machine Co., and the Q. M. S. Co., sends us a short description and picture of the Hanna vertical suction-oiler. It is automatic in action, and gives the correct quantity of lubricant at the right time.

Bulletin 11D of the NATIONAL TUBE Co., Pittsburg, in 48 pages discusses the history, characteristics, and advantages of 'National' pipe. Bulletin 24 covers the rise in steel pipe. In 1905 wrought-iron pipe made was 452,797 tons, and steel, 983,-198 tons; in 1913, the respective figures were 312,746 and 2,-189,218 tons.

In a 42-page catalogue the LOCOMOBILE Co of America, at Bridgeport, Connecticut, illustrates and describes its 3 and 4-ton worm-drive trucks. These are lighter, more mobile, and more economical than the 5 and 6-tonners. The overhead type or straight worm drive is used. The worm is of nickel-steel, hardened, and the teeth ground after hardening. These trucks are suitable for all kinds of work, including carrying coal, water, oil, pipes, ore, and concrete materials.

The frontispiece of a 30-page booklet of the MINE & SMELTER SUPPLY Co., Salt Lake City, Denver, El Paso, and New York, shows No. 86 in the erecting-shop, one of twenty Marcy ball-mills for the Inspiration copper mill, Arizona. This machine is gaining favor in many centres. It is designed and built to sucessfully take the discharge of jaw and gyratory-chusher, 2 or 4 in., and with 'One Easy Step' produce a non-selective product of 10, 20, 40, or 80-mesh, all passing the meshes given. An article on the practice and design of wet-crushing ball-mills is giveu by F. E. Marcy. Both plain and herring-bone gear is made for these machines.

The MORSE BROS. MACHINERY & SUPPLY COMPANY, of Denver, Colorado, has purchased the entire power plant recently erected at Wilkenburg, Arizona. This plant was built to furnish power for the Octave Mining Company, 14 miles distant. The power being generated at the railroad and transmitted to the mine. The plant consisted of 200 and 550 kw. Westinghouse generators driven by Corliss engines. The steam plant consists of B. & W. boilers, fired with oil. The transmission line was operated at 22,000 volts, and is fourteen miles long. All of this material will be dismantled and sold, or removed to their Denver house. The smaller unit was in use three weeks, and the larger one was never used.

EDITORIAL

T. A. RICKARD - - - - Editor THOMAS T. READ - Associate Editor

JAPANESE copper is arriving in London. Japan produces about 75,000 tons of the metal per annum.

THE index to volume 110 of this journal has been prepared and will be sent to any of our subscribers, on request.

STEEL is the barometer of industry. Conditions in the steel industry are reflected in the quotations for United States Steel Corporation shares. The rise is significant.

EXPORTS of zinc from Australia to the United States have been sanctioned by the British government to the extent of 50,000 tons of concentrate, averaging about 47%. It remains to be seen whether that amount can be marketed here.

DECLARATION of war by the United States would be followed by the intensified manufacture of munitions and an insistent demand for copper, lead, zinc, and antimony. Yet we hope that no such declaration may prove necessary.

NOTHING has come of the investigation into the alleged spelter trust. Officials in Missouri have been able to find no evidence to justify the allegation that the price of ore was fixed by the buyers at Joplin. We considered it a mare's nest from the start, although always wishing well to the producers of ore in Missouri, and elsewhere.

CONDITIONS in Mexico are discussed in special correspondence from Mazatlan and London. We also give some notes on the currency problem in Sonora. The National City Bank of New York estimates that paper money to the nominal value of 1,000,000,000 pesos has been forced upon the population of Mexico during the last 18 months.

GAMBLING in war stocks has been the chief characteristic of Wall Street dealings for several months. It is exciting, and fully as dangerous as dancing on the edge of a volcano. Eventually there will be a lurid day of reckoning. Meanwhile it makes the market highly professional, for the public is, we are glad to think, abstaining from the orgy.

IMPORT of a single shipment of 300 flasks of quicksilver from Italy into New York two weeks ago is accompanied by the explanation that the embargo on exports of quicksilver from that country has not been relaxed, but the single shipment was allowed to proceed, as it had been contracted and paid for before the embargo was declared. No further shipments will be permitted.

HAVING been through the ordeal of fire ourselves, we sympathize with our vigorous contemporary the *Valdez Daily Prospector,* which was burned out of house and home on July 15. However, on the same day a single printed sheet was issued just to show that it is not paper and machinery that make a newspaper, but the spirit that gives life to the printed word. We congratulate our friend in the North.

ACCORDING to current statements the loans issued by the belligerents in Europe make a total of $16,000,000,000; it is estimated that the casualties to date in the War (that is, dead, wounded, and prisoners) amount to 10,000,000 men; we estimate the horror and suffering caused by the War at $1,000,000,000

ton. An operating cost of 64 cents per ton is reported, as against the estimate of 75 cents. Even allowing for a small addition to cover depreciation and overhead charges, this is a notable achievement.

PROSPERITY is warming the hillsides and canyons of the mining districts tributary to Salt Lake. On the first day of August the increase in wages granted voluntarily by the mine operators goes into effect. From 15 to 25 cents more per working shift is to be paid; this means that $750,000 more per annum is to be distributed in the region as a whole. The new wage-scale affects 7000 men.

LITIGATION is much in the air. While the Emma Copper company, in the Little Cottonwood district, Utah, may escape an apex-suit, said to be threatened by the owners of the Cabin claim, it is a fact that two suits have been started by the North Star Mines Company against the Empire Mines & Investment Company at Grass Valley, California. This promises to be a complicated case, involving geological and legal evidence of a most interesting character. However, it relates to the ownership of a magnificent orebody, of which the larger portion remains yet to be extracted.

ON another page we publish a copy of the contract under which Bolivian tin concentrate is sold to European smelters. We are indebted for this to Mr. Luis Abelli, commissioner for Bolivia to the Panama-Pacific International Exposition. Much attention has been given during the past year to the possibility of smelting Bolivian tin concentrate in this country, and, in thus making public the terms under which the business is usually negotiated, Mr. Abelli renders timely assistance to the firms that are considering a venture in the smelting of South American tin ores.

IN Mr. T. J. Hoover's book—the only book—on 'Concentrating Ores by Flotation,' he gives the average royalty levied by the process-owners as 25 cents per ton. The combined capital of all the companies exploiting the flotation patents is about $5,000,000. Therefore royalty at 25 cents per ton must be paid on 20,000,000 tons of ore before the capital is returned. These companies have been in existence for over 10 years, so that if they return 10% per annum, as they should, they must treat 20,000,000 tons more. As yet they have done about half of this total requirement of 40,000,000 tons. As Mr. Hoover suggests, this simply indicates that they have been overcapitalized and burdened with the cost of litigation.

The Mexican Impasse

Mr. Roosevelt, in his speech at the Exposition, referred to Mexico and said: "Conditions in Mexico are such that, unless the Mexicans themselves come to their senses and unless we are content to see foreign powers undertake the regulation of Mexico, we may ultimately have to intervene. Such intervention would not represent real war, but a work of pacification and police." From Washington it is reported that "a definite step toward settling the Mexican problem will be taken by the United States government in the near future." It sounds familiar, but we believe it to be true. Indeed the Mexican habit of mañana characterizes all things Mexican, even the vital problem of restoring law and order. It is said the graver responsibilities of the President in regard to the European position prevent him from proceeding with his efforts to help the Mexicans in obtaining some sort of government. On the contrary, we venture to surmise that the Mexican trouble may prove a timely safety-valve for the belligerent spirits in this country. If some expression of activity is required it would be well to direct it across the Rio Grande rather than over the Atlantic. Events continue to have what seems to us a favorable trend. Zapata and Villa are in a weak military position and show a willingness to co-operate with the peace-makers. Carranza talked big for a time, but his affairs also look none too promising. Important defections from both sides are reported and several leading men not too closely aligned with the existing factions are making a move looking toward some form of co-operation. Felipe Angeles, Eduardo Iturbide, and Eulalio Gutierrez are mentioned, besides Maytorena and some of the Madero family. This looks promising. Meanwhile both the Mexican people and the South American governments are becoming reconciled to the idea of American assistance in restoring a national government in Mexico, for it has been shown beyond a doubt that the United States has no sinister designs on its neighbor's property.

The Amateur Miner

A few days ago we received a visit from a gentleman who came to ask our advice in regard to the best way of taking an active share in the business of mining. That probably was not the way he would have phrased it when he handed his card in the outer office, but that assuredly was the idea at the back of his head. He was the type of quiet-mannered and well-educated New Yorker, with plenty of money and time on his hands, prompting him to a financial adventure on the romantic frontier of mining. He said that in New York he had met a man named Blank, who was an experienced miner and was willing to set out in search of a mine, if provided with $125 per month and allowed a half-interest. The New Yorker—let us call him Mr. Gray, for that was the color of his habiliments—asked us if we knew anything about Blank; to which we replied in the negative. We advised him that the proposal was an ordinary 'grub-stake,' which was excellent when the contracting parties knew each other, but inadvisable when one of them had all the money and the other all the experience. Thereupon he asked us what we considered the best way of participating in mining. That was a large question. We asked him several in exchange and ascertained that Mr. Gray did not care to buy shares; he thought it foolish and highly uninteresting to become a minority shareholder, for he wanted to take part in the actual organizing and

operation of a mine. Thereupon we suggested that before he committed himself financially to any scheme, he should visit a number of mining districts. If he cared to ride, he might take a horse and go from Mariposa to Plumas county, the whole length of the Mother Lode, stopping at the various mines on the way, so as to obtain information, not only at the mines, but by conversation with the people he would meet in the course of his pilgrimage. However, it appeared that he was more of a yachtsman than a horseman, so that idea did not bite. Then we suggested a motor-car and a tour through Amador, Grass Valley, Reno, Tonopah, Goldfield, and Ely, assuring him that three months of intelligent observation would open his eyes so that he could proceed with more safety on his proposed mining venture. After such a preliminary canter, we thought he should return to New York and discuss the matter with one or two mining engineers of his own social stratum, members possibly of his club, the name of which he divulged. We mentioned two engineers who themselves were looking for possible mines, men of experience and technical training, as well as of capital, who might be willing to admit him to a participation in a venture with a risk much less than that to be incurred by him if he played a lone hand. He rather liked that suggestion, and politely accepted one or two names and addresses. If he had the necessary capital and was seriously bent on sane speculation in mining, he would, we felt sure, obtain a run for his money under the guidance of the men mentioned. Having obtained preliminary experience in their company, he would acquire a first-hand knowledge of the mining business, sufficient to warrant him in proceeding on his own initiative, provided always that he took, and paid for, the advice of an experienced mining engineer before committing himself heavily.

That, frankly, was our advice. Perhaps some of our readers can suggest a better method of starting an inexperienced man on the difficult road of an intricate business. We shall be glad to publish their views.

About Flotation

In this issue we publish a few interesting details concerning the application of the flotation process to copper ore at Engels, in California. Mr. T. T. Read describes how an ore not amenable to ordinary wet concentration is being treated by flotation, yielding a concentrate rich enough to warrant shipment to the Garfield smelter, in Utah. This is not the only flotation mill in California, for the Mountain Copper Company is operating a Minerals Separation flotation plant having a capacity of 250 tons of ore per day, using an acid solution. The little mill at Engels, however, is notable because it represents a single treatment, not a mere supplement to older methods. At Miami, for instance, 40% of the ore is submitted to wet concentration only and is never touched by froth, while 30% is treated by flotation only, leaving another 30% that undergoes successive treatment, first by water and then by oily froth. At the Butte & Superior, on the other hand, while 40 to 50% of the concentrate made in the mill is the result of tabling and jigging, there is no discard except from the flotation department.

In all of these cases the metallurgical treatment is not completed; it stops at the stage of producing a concentrate, without attempting to extract the metal itself. This will suffice for copper ores, particularly in districts tributary to established smelters, but the concentrate from a gold and silver ore will invite further reduction on the spot, to the point of an extraction expressed in terms of bullion.

Our own information leads us to conclude that trials are being made with the new process—'new' in its latest phase—in localities all over the country. The intelligent curiosity of the mining public has been aroused to the importance of this method of concentration and every wide-awake millman or metallurgist is applying it tentatively to his own ore. Tests can be made easily because the process requires no elaborate apparatus. For instance, in the case of many ores mere shaking of pulp with a little oil in a bottle will suffice to make a separation, as is indicated by the simple tests made by the California University students, whose amateur but intelligent research is recorded on another page of this issue. Again, an ordinary soda-water siphon can be used, if only the cap of the bottle is strengthened so as to permit of the pressure within the bottle being raised by a bicycle-pump to, say, 30 pounds per square inch. A charge of 4 ounces of powdered ore, 12 ounces of water, and a few drops of oil (say, in the proportion of half a pound of oil per ton of ore) is introduced into the bottle, which is then shaken vigorously so that the air will dissolve in the mixture. Then the lever is depressed and the foaming contents discharged into a beaker, where separation ensues, the froth remaining on top, with its burden of mineral, while the particles of gangue sink to the bottom. The operation is essentially one of separating valuable mineral from valueless gangue by means of the selective action of the froth on the particles of the former. Another simple type of apparatus for a small test is the separatory funnel used in ordinary analytical work. As for oil, the coal-tars, creosotes, and pine-oils can be used, the thicker tars being thinned by the addition of a little turpentine. In some parts of the world, eucalyptus oil will be easiest available. The siphon method and other simple devices for making tests are described in Mr. T. J. Hoover's book on 'Concentrating Ores by Flotation.' This is the only book on the subject and has a timely value it would be difficult to exaggerate, for the information available on the process is singularly small. In various technical publications the student will find references to the various patents and to the litigation incidental thereto, but to the average man most of this information is vitiated by prejudice, and therefore confusing. The tax on knowledge imposed by patent litigation has never been more unpleasantly manifest than in this department of metallurgical work.

The making of tests, of course, does not involve the payment of royalty to anybody, but with the first at-

tempt to operate the process on a commercial scale there rises the bogey of the patent-owner. Just now the principal patent is the subject of litigation, so that it is not known who, if anybody, has the right to collect a royalty, but the uncertainty may be cleared, in some degree, at an early date, by a decision in the cases now pending. That of Minerals Separation *v.* Hyde was won by defendant on appeal and then by writ of *a certiorari* it was brought before the Supreme Court, where it now rests. Meanwhile the more recent suit of Minerals Separation *v.* Miami, supported by several other important copper companies, will be adjudicated by the District Court at Wilmington in October and will then go to appeal, of course. The decision in the one case may affect the other, but the present litigation will not be settled until the court of last resort has given its opinion. Indeed, the real scope of a patent is not defined until it has passed through the ordeal of successive lawsuits. Then it emerges in the form of a chastened statement sufficiently definitive to warn infringers of their legal limitations. It is a pity that the legal machinery should be so cumbersome as to necessitate years of expensive litigation in order to determine the relative rights of the inventor and the public. These rights could be adjudicated in a single hearing if brought before a court constituted to try such issues only. It is regrettable that the owners and the users of metallurgical ideas or devices should have to descend into the dusty arena of the law-courts. The performance is always expensive and usually unsatisfactory. Before the critical case between Minerals Separation and the Miami company went to trial, several sincere efforts were made to compromise the difference. These efforts failed, as similar previous efforts in London had failed likewise to find an adjustment of conflicting claims. Oil, it is said, stills the troubled waters; but it has a curiously belligerent, if not vindictive, effect upon inventive metallurgists and their patrons. Perhaps it is the acid that causes the acerbity; then we may hope for gentler feelings when the alkaline treatment is generally adopted. In truth, much of the trouble is due to ignorance of human nature; or the ignoring of it, shall we say? For instance, we ask a metallurgist what royalty he would demand if a device of his enabled a mine to save an additional 40 cents per ton; he replies, 5 cents. That is an eighth. When we inquire what royalty the Miami is expected to pay Minerals Separation, we are informed that it is at the rate of $\frac{3}{8}$ cent per pound of copper, but never less than 12 cents per ton of ore treated by the process. That seems not unreasonable, but on a big tonnage, over many years, it is considered oppressive. An extra saving of 10% on a 2% copper ore, with copper even at 15 cents, represents 60 cents per ton. To pay a fifth of the saving may not appear excessive to the onlooker, but to the payer it looms unpleasantly large. The latter would prefer to pay a lump sum and get rid of the incubus. The restrictions imposed on the licensee are apt to prove irritating and the effort to monopolize knowledge is bound to provoke resentment. As a matter of fact, the money made from metallurgical improvements usually is not derived from royalties so much as from the manufacture of the plant and the engineering services that go with it. If a patentee or a company owning a patent has devised an effective process or a successful machine, it is wise to employ his or its experience in the application of the process or the machine, and, provided the royalty charged is not oppressive, it is advantageous for the operator to go to him or it for engineering services in the erection of a plant of which the process or the machine may form only a part. This is the story of the successful work done by Charles Butters, J. V. N. Dorr, H. W. Hardinge, Alfred James, C. W. Merrill, E. A. C. Smith, and other inventors. The average man has a natural dislike to looking down the barrel of a pistol—even if it is not loaded.

Oil Films on Water

Students of the physics of flotation as applied to ore-dressing will do well to familiarize themselves with the researches of M. Henri Devaux, professor in the University of Bordeaux, who has for the past fifteen years been engaged in investigation of the phenomena exhibited by oil-films on water-surfaces. A résumé of his papers on this subject was published in the Annual Report of the Smithsonian Institution for 1913. Among the most significant discoveries of M. Devaux is that when oil is dropped on the surface of water it spreads out into a film one molecule thick. In carrying out his investigation he used a dilute solution of tri-oleate of glycerine in benzol; when this is dropped upon water it spreads out and the benzol evaporates almost instantly, leaving behind a thin film of oil. Knowing the area covered by the oil and the volume of the oil used, he was able to calculate the thickness of the film, finding it to be one-millionth of a millimetre, or approximately one-twenty-five-millionth of an inch. This corresponds very closely to the known value for the diameter of a molecule of tri-oleate of glycerine. M. Devaux further determined by experiment that if a larger quantity of oil than that required to yield a film of this thickness is used a thicker film is not formed, but the excess of oil gathers together in drops, leaving the film elsewhere at its normal thickness. The data gathered in this and other investigations have been employed by M. Devaux in the study of molecular phenomena, but it serves as a good example of how research of apparently the most academic character may serve to throw light upon industrial processes. If films of oil on water are only the thickness of a molecule, it is no longer puzzling that a small fraction of a pound of oil per ton of ore is so effective in ore-dressing by flotation, nor that the use of larger quantities of oil does not improve the results attained. No doubt many other facts learned by workers in the field of pure science can be applied to elucidate the phenomena of flotation. We recommend investigators in this new branch of metallurgy to familiarize themselves, so far as practicable, with the work of investigators in related fields of research.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more vaulable than casual compliment.

Mining Claims in National Forests

The Editor:

Sir—In the July 10 issue of the PRESS is an article on 'Mining Claims in the National Forests' that on its face is beyond criticism, but, like all such articles, it ignores the principal objection to the administration of the Forest Reserves, namely, that while Congress authorized the establishing of Forest Reserves for a specific purpose, that purpose has been used as a blind under cover of which forest reservations have been established not only in disregard of the purpose of Congress, but in absolute defiance of the express provisions of the statute. One section of the Act of June 4, 1897 is as follows: "No public forest reservation shall be established, except to improve and protect the forest within the reservation, or for the purpose of securing favorable conditions of water flows, and to furnish a continuous supply of timber for the use and necessities of citizens of the United States; but it is not the purpose or intent of these provisions, or of the act providing for such reservations to authorize the inclusion therein of lands more valuable for the mineral therein, or for agricultural purposes than for forest purposes." A President of the United States, at the request of the Forester, set aside as Forest Reserve mineral land in Colorado above timber-line, mud-flats in Alaska that are washed by the tide every day, sage-brush deserts in Arizona and New Mexico, and treeless table-lands in Colorado. These reservations were made, not to protect timber and watersheds, as Congress directed, but to control the location of mining claims, to levy a tax on the livestock industry in the case of grazing lands, and in the case of the mud-flats on the border of Controller bay in Alaska probably for the purpose of obtaining revenue by leasing to shipping interests. But whatever their object, these reservations were not only gross usurpation that are not entitled to be treated with respect, but are deliberate violations of the statute. When mining men object to having their mining locations controlled by Forest Reserve officers, it is usually because the forest reservations have not been made in accordance with law, and because the law makes the Secretary of the Interior the person who is to decide whether an applicant is entitled to a patent for his claim and not the Secretary of Agriculture. It is, I think, beyond question that Congress authorized the establishing of forest reserves for the sole purpose of preserving the forests on the watersheds of our streams. It is equally beyond question that the Forest Reserve system has been extended over portions of the public domain, not for the purpose of protecting forests, but as a scheme of commercial landlordism for revenue, for which there is no authorization in the law, and it is this usurpation of authority that causes the clashing with mining interests.

H. W. REED.

Salt Lake City, July 15.

The Editor:

Sir—That Mr. Reed is in error regarding the facts is shown by the very wording of the statute the provisions of which he asserts to have been defied. While the Act of June 4, 1897, as Mr. Reed points out, declares that "it is not the purpose or intent of these provisions, or of the act providing for such reservations, to authorize the inclusion therein of lands more valuable for the mineral therein, or for agricultural purposes, than for forest purposes," the same Act in a later section makes the following provision:

"Upon the recommendation of the Secretary of the Interior, with the approval of the President, after sixty days' notice thereof, published in two papers of general circulation in the State or Territory wherein any forest reservation is situated, and near the said reservation, any public lands embraced within the limits of any forest reservation which, after due examination by personal inspection of a competent person appointed for that purpose by the Secretary of the Interior shall be found better adapted for mining or for agricultural purposes than for forest usage, may be restored to the public domain. And any mineral lands in any forest reservation which have been or which may be shown to be such, and subject to entry under the existing mining laws of the United States and the rules and regulations applying thereto, shall continue to be subject to such location and entry, notwithstanding any provisions herein contained."

In other words, Congress recognized that in establishing National Forests covering the main mountain ranges of the West for the purpose of conserving water and growing timber, mineral lands would of necessity be included, and therefore the law made definite provision for such cases. This provision was of two kinds. The law provided that the existing mining laws of the United States should apply in National Forests to any mineral lands "which have been or which may be *shown to be such.*" It also authorized (but did not command) the Secretary of the Interior to restore to the public domain any lands which might be found better adapted for mining or for agricultural purposes than for forest

usage. It is to be noted, however, that in authorizing this action Congress was careful to stipulate a procedure providing many safeguards against ill-advised action or insufficient information, the result of which might be to defeat the purposes contemplated in the creation of National Forests. How, then, can Mr. Reed hold that the reserves were made in violation of the law?

It is surely unnecessary for me to point out that the assertions in the letter to the effect that great reservations were made, not to protect timber and water-sheds, but to control location of mining claims and for other purposes not authorized by the Act, are entirely baseless. While many persons formerly accepted without question sweeping statements of this kind, increased knowledge of the facts regarding the National Forests and the methods and purposes of their administration makes discussion of such appeals to public credulity superfluous. The mere lapse of years since such charges began to be circulated, without effect, in the form of legislation to remedy the alleged wrongs done, should suffice to show that these wrongs are non-existent. Otherwise action would have been taken long ago.

L. A. Barrett,
Acting District Forester.

San Francisco, July 23.

Timber on Mining Claims

The Editor:

Sir—I note in your issue of July 10, 1915, under the title 'Concentrates,' the following paragraph:

"Where two contiguous claims, one having timber on it and the other none, are held by one owner he may take the timber from one claim and use it for development work on the other."

It is believed that this statement does not go far enough in indicating the right of a miner to take timber to support his improvements on a group of claims. This right to take timber is governed by Section 49 of the Penal Code, Act of March 4, 1909 (35 Stats. 1098), prohibiting the cutting of timber on public lands of the United States. This section also provides:

"Nothing in this section shall prevent any miner or agriculturist from clearing his land in the ordinary working of his mining claim, or in the preparation of his farm for tillage, or from taking the timber necessary to support his improvements, or the taking of timber for the use of the United States."

It has been established from the wording of this section and by decisions under it, that if timber is cut from one claim of a group and used upon another, the taking of the timber must tend to develop the claim from which the timber is cut as well as the claim on which it is used. In other words, claims cannot under the law be located merely for the purpose of securing the timber upon them. The intent of the law was to secure to the miner the right to use the timber upon a claim for its development. If a timbered claim is located but no development of it is contemplated or attempted and the timber on it is used on other claims in the vicinity, such use would not be authorized.

L. A. Barrett,
Acting District Forester.

San Francisco, July 21.

Mining Machinery Buyers

The Editor:

Sir—I have read Mr. McDonald's article on 'Mining Machinery Salesmen' with keen appreciation. The selling of mining machinery is more than a mere occupation, it is an art, and therefore allowance must be made for the display of temperament on the part of its many exponents.

Responsibility for such display of temperament must in part, at least, be borne by the buyer, who is often "coy, uncertain, and hard to please." Many learned books have been written with the avowed aim of enabling the reader to arrive at a rational understanding of the psychology of sales. Nevertheless, they have failed to reduce the business to a formula.

Many buyers of machinery regard the salesman and his employers as legitimate game for which there is no close season. Here is a case in point: Some years ago, a well known mining company purchased a large hoisting-engine. Shortly after its arrival on the ground, a claim was made by the mining company for the replacement of the drum, on the ground that the casting was defective. The company was a large and important one, and, what is even more to the purpose, an extensive buyer of machinery and supplies. The manufacturer, in consequence, did not question the truth of the claim, and obligingly supplied a new drum at its own expense, the cost amounting to several hundred dollars. At a visit to the property several months after, the writer learned to his disgust that the reason for the breaking of the drum was that by careless handling, it had been dropped over a bank and cracked beyond hope of repair. The mine superintendent had actually boasted of his shrewdness in thus obtaining a new drum without cost to his employers.

When the day of judgment comes, and the just and unjust are duly separated one from the other, I have no doubt that the majority of mining men will be classified with the former. But there are some who will not.

Here is another irritating trick that has been played on the selling fraternity time and time again, and, I suppose, with some modern improvements, is still being worked in one form or another.

One fine morning, an inquiry for a 20-stamp mill came in through the mail from a small Middle-West town. It bore all the earmarks of genuineness; the specifications had been skillfully prepared, and, in short, it appeared to be a prospective sale worthy of attention. In due course, figures were prepared and submitted by mail, and the result awaited with eager expectancy. Several weeks had elapsed when a telegram was received from the prospective buyer reading something like this: "Bids will be opened for stamp-mill on the tenth. We hope

you will arrange to be represented." Joy pervaded the salesman's office. The prices must have been favorable; if not, why the telegram? However, in order to make assurance doubly sure, a reply was telegraphed to the buyer, who then responded: "Your prices among the most favorable received. Look forward to seeing you." Then followed a visit to the cashier, a rush to the train, and a 1500-mile journey across the continent, during which sweet dreams of anticipation were accompanied by the clicking of the wheels as the miles fled past.

Upon arrival at his destination, the salesman, in the dark of the evening, picked his way from the depot to the one hotel, opened the door, took a look within, and then, tableau!

Nothing but machinery salesmen; salesmen, salesmen, everywhere and not one drop to drink. It was a 'dry' town.

Upon comparing notes, and there is a certain community of spirit among salesmen, even with the deadliest of rivals, it soon developed that precisely the same telegrams had been exchanged between the prospective buyer and all of the others present.

The object of such tactics is simple. It is merely to get as many salesmen as possible together on a single quest. Then by pitting one against the other and permitting an unlimited number of revisions of the bids, to say nothing of letting any one know what all the others have bid, the buyer takes advantage of the reluctance of the hunter to going home without any game, and buys what he wants at a figure close to the limit of endurance of the manufacturer.

Eight of the salesmen present withdrew their bid and declined to take part in the auction. Two remained and bid against one another until one reached the low-water level, and left the victor in possession of the field, triumphant, perhaps, but facing a problematic gain in prestige at the cost of a contract taken at a sure loss. The total expense account for those present aggregated about $1500, which had to be charged against the high cost of selling.

The real buyer of mining machinery, especially when taken in his native habitat, is another man altogether. These exceptions, for exceptions they are, are as opposite to him as the two poles. A busy man always, with a weight of responsibility on his shoulders, nevertheless he is ready with a courteous and hospitable greeting to the visiting salesman. He will permit himself to be bored by the loquacious, irritated by the man who knows nothing but 'talking points,' and will suffer in silence from the typical story-teller. Nevertheless when the dinner bell rings, his invitation to "join us" will have lost none of its heartiness thereby. He is receptive to new ideas, but is conservative with the Missouri tendency that asks to be 'shown.' I count among the pleasantest experiences of my life the men I have met in this way and have since learned to call 'friend.'

Here's to the machinery-buyer, God bless him. I wish there were more of them.

C. T. Hutchinson.

San Francisco, July 15.

Rare Chances

The Editor:

Sir—Apropos of the story of the Columbia student in the editorial 'A Rare Chance,' in the Mining and Scientific Press of July 3, I should like to tell a similar one. I was at Cobalt in 1910 and visited what is now the Seneca-Superior mine, then being operated under another name. Mr. Jackman, the manager, invited me to dinner in the combination office-and-dwelling where he 'bached.' The mining territory consisted of a tract under a lake with the customary strip of 33 ft. along the shore for buildings and shaft. The mine had never done much. After spending a fair sum of money in sinking and driving, all then disclosed was one or two little bunches of high-grade ore that scarcely served for more than samples to show to visitors. Before the company could make any money it had obligated itself to pay 25% of the ore-returns to the owners of the mining rights, and 25% more to Mr. Jackman and his partner, Mr. Segsworth of Toronto, who had sub-let the property to the mining company. The latter was financed by somebody in Rochester, N. Y. It seemed that the most one could say for the mine was that it was near the big Nipissing; a doubtful compliment at Cobalt, since a whole string of properties near real mines had proved valueless.

Later, when I was in Michigan, Mr. Segsworth wrote me explaining that the company had been re-organized, and offering me some of the new stock at a very low price per share. He enclosed blue-prints showing what had been found underground, etc., and wished me to try to interest Lake Superior people in buying some of the stock. I talked to several mining men about it, explaining that I had been at the mine, etc. One man in New York state seemed interested, and said "There might be something in this thing," but he was a friend of mine and I advised caution. Finally nothing came of it, and other things arose to divert my interest. As opposed to this do-nothing course, an engineer at Syracuse, N. Y., put all his savings into the same stock, Seneca-Superior. The mine immediately after struck it rich; the stock went up rapidly and he cleaned up a fortune.

P. B. McDonald.

Boston, June 10.

The gold-bearing areas of Turkestan have been little prospected. Gravels on several rivers are washed in a primitive manner. Dredging and hydraulicking are possible. Lode mining deserves attention. Transportation facilities are not good at present.

Manganese ore production of the United States last year was only 2635 tons, a decrease of 1413 tons. Imports totaled 283,294 tons. India, Russia, and Brazil supplied most of this.

Gypsum production of the United States in 1914 was 2,476,465 tons, a decrease of 123,043 tons. The marketed value totaled $6,895,989. New York is the largest producing state of this mineral.

Froth and Flotation

An Early Recognition of the Importance of Froth in the Flotation Process by Three Students at the University of California

In the issue for November 1903 of the *California Journal of Technology* there appeared an article describing the experimental work done on oil-flotation by three senior students in the University of California. The article is entitled 'Experiments on the Elmore Process of Oil Concentration' by W. F. Copeland, Drury Butler, and Jas. H. Wise.

At the outset they state:

"The process depends upon the fact that minerals with a metallic lustre, when treated in the form of a wetted pulp, adhere to oil, while earthy minerals do not. Two distinct operations are involved; first, the separation of the metallic mineral from the gangue by means of oil; second, the extraction of the mineral from the oil.

"The ideas underlying the first operation were patented by John Turnbridge of Newark, N. J., in 1878. In 1886 Carrie J. Everson, of Chicago, contributed the idea that the concentration was aided by the presence of an acid solution, and patented the same. But the absence of a successful method of separating the mineral from the oil prevented the practical application of these early patents. Burning the oil was tried, but this left a difficult residue to treat, and the large consumption of oil made the method too expensive. Settling the mineral out by thinning the oil with gasoline, ethers, carbon-bisulphide, etc., also proved too expensive, and it was not until July 1900 that this difficulty was overcome, when Mr. Francis E. Elmore, of Leeds, England, accomplished the separation by means of a centrifugal machine, similar in most respects to those used in sugar factories and in milk and cream separation. This contribution by Mr. Elmore, then, made the process feasible."

[They give an illustration of the plant designed by the Oil Concentration Syndicate and describe the operations. Their own apparatus is shown in photographs and they give details of the tests made on various ores. In brief, they obtained the following results:

Character of ore	Extraction %
Gold-quartz ore	86
Silver ore	75
Copper-schist tailing	90
Molybdenite ore	75

They describe the nature of their experiments and comment on the facts disclosed in a most intelligent way. We quote the salient paragraphs.]

"In making a test, the ore is first crushed to the desired fineness, and the proper charge is thoroughly wetted in the solution to be used (usually water), thus forming a thin pulp. The oil is next added and the whole charge thoroughly mixed. This mixing, or agitation, can be done in two different ways: The charge may be agitated very gently, the oil being kept in a single lake, and broken up as little as possible consistent with a thorough contact of pulp and oil; or the charge may be agitated so violently as to dash the oil up into a foam or froth, full of air bubbles; thus a very thorough contact of oil and pulp is obtained. * * * * * *

"Three methods of mixing may be used.

1. By inverting the tube several times, thus allowing the ore to fall through the oil.

2. By rotating the tube in a horizontal position, thus throwing the pulp up on to the surface of the lake of oil.

3. By violently shaking the tube, thus producing the *foam effect*,* or at least shattering the oil into small globules."

* * * * * *

"The solution used in the concentration is a matter of some importance. Water is, of course, used whenever possible, but certain other solutions have important advantages. As before stated, an acid solution is found advantageous. It cleans the metallic surfaces by dissolving the metallic oxide coatings that may have formed on them. It increases the specific gravity of the solution, and it aids in producing *the foam effect*, which is due to the generation of certain gases.

As before stated, the specific gravity of the average oil used is about 0.9 and water 1.0†, leaving a difference of about 0.1 for buoyancy or carrying capacity of the oil.

The idea at once suggests itself that if a denser solution be used, the carrying power of the oil will be increased correspondingly. A salt (NaCl) solution, for instance, gives excellent results. A saturated solution of NaCl at 20°C., containing about 27% NaCl, has a specific gravity of 1.204. This gives a difference of 0.3 between the specific gravities of the oil and of the solution, and a carrying capacity of the oil threefold greater than with water alone. Not only does it give a greater bouyancy to the oil, but *it also aids materially in producing the foam effect*, and probably aids in brightening the metallic surfaces."

* * * * * *

"As a conclusion to the above experiments, the following suggestions and inferences are appended:

1. As Regards the Wetted Pulp.—As far as could be determined, particles with either metallic or non-metallic surfaces, when in the dry state, alike adhere to the oil. Furthermore, there is no affinity of oil for water, as is shown by the fact that an oiled surface cannot be wetted. Hence if a metallic particle be thoroughly

*[The italics in all these quotations are ours.—Editor.]

†[In the original it is .1.—Editor.]

wetted, a water surface and not a metallic surface is exposed to the oil; and the former, as before stated, has no affinity for the oil. It is evident then that the water film must first be displaced before the oil and mineral can come in contact with each other. This displacement is hardly probable if the water film is in intimate contact with the particle, and it seems more probable that the differentiation is due to the fact that non-metallic surfaces are, and metallic surfaces are not, actually wetted. If this be the case, a careful study of the relative wetting of different surfaces would be an important line of investigation.

2. The ratio of the exposed surface to the weight of the particle should be as large as possible, because the total adhesive force is increased with an increase of the surface exposed to contact with the oil. This condition is best realized when the mineral breaks up into thin flakes. It is evident from this that a knowledge of the fissile character of the minerals in question is important.

3. One fundamental difficulty involved in this process is that it undertakes to concentrate and float a heavy metallic mineral, and sink the lighter gangue minerals, but this point is not necessarily fatal to the process. It is evident, however, that the heavier the gangue and the lighter and more fissile the metallic minerals, the better the ore is adapted to this method of concentration. This is a direct reversal of the ideal conditions for jig or vanner concentration.

4. Another characteristic of the proces is the fact that the ratio of concentration is usually small, due to the large amount of gangue occluded by the oil and carried into the concentrates. This difficulty is increased by sliming the gangue minerals. Sliming of the metallic minerals is no disadvantage.

Foam Effect.—*The foam effect is produced by a violent agitation, especially in acid or salt solutions. This throws the oil into a froth, which is heavily charged with air or other gases. This gas, of course, gives a greatly increased buoyant force. The oil in this condition assumes a certain load of mineral and holds it in a very stable condition. The charge does not settle and overload on standing* as in the case of the lake effect. The foam effect is best adapted for light flaky minerals, such as molybdenite.

The work above outlined suggests many lines of further investigation, and as these come to be worked out, the process will become more valuable and of more general application."

[It is clear that they had a good idea of the usefulness of the froth, and how to make it. In the employment of salt and acid, they anticipated G. D. Delprat, for his British patent for the use of salt and sulphuric acid was taken out on December 11, 1903, that is, two months after this article was published. The early work of C. V. Potter (patented on January 14, 1902) and G. D. Delprat (beginning with a patent dated November 28, 1902) did not involve the use of oil, but the generation of gas in the pulp to form bubbles. Alcide Froment (under patent dated June 4, 1902) connected the oil and bubble ideas, and it is his patent that forms the basis of the Minerals Separation process, to which in 1905 (and particularly November 6, 1906) were added several patents obtained by H. L. Sulman, H. F. K. Picard, and John Ballott, for the agitation-froth process. Thus these three students at the University of California had touched upon an idea destined to be of the greatest importance in metallurgy, but they did not know it. In the very same issue of their *Journal of Technology* there appears an article on 'The Method of Obtaining Letters Patent.' The irony of the juxtaposition is evident now. We note that the manager of this student publication was Arthur H. Halloran, then a junior in the University. He became a member of the staff of the Mining and Scientific Press after graduation and for some time after his father, J. F. Halloran, sold the control of the paper to the present writer. However, it may not be so surprising that these young fellows failed to appreciate the importance of the suggestions obtained in the course of their experimental work, but it is truly remarkable that a keen investigator like their professor, the late Samuel B. Christy, should have overlooked it, at a time, too, when he himself was at work on kindred research, more particularly in cyanidation. It may have been his absorption in the one part of the subject that prevented him from obtaining the right focus on these—now, to us—deeply suggestive experiments.—Editor.]

Removal of Selenium and Tellurium in Copper Bullion Assays

By GEO. L. HEATH

When selenium and tellurium elements are the principal impurities present in a copper bullion they may be successfully removed by a very simple scheme which takes care of the objection that these metals, under certain conditions, form compounds with silver, or copper, when reduced with sulphur dioxide.

The nitrate solution is evaporated with an excess of sulphuric acid until the dry residue is white. Dissolve in 60 cc. of water and wash into a lipped beaker, placing the tall beaker under a funnel fitted with a 3-cm. filter. Heat the solution to boiling, remove from plate, and charge with SO_2 gas for 10 min. Gas, free from chlorine, is generated by slowly dropping a saturated solution of C. P. sodium sulphite from a separatory funnel into a large round-bottom flask half filled with concentrated C. P. sulphuric acid. After settling a few hours, at least, filter into the original electrolytic beaker, and wash free from acid with hot water. Boil gently to remove most of the sulphur dioxide gas. Ignite the filter in a porcelain crucible at a red heat until the residue is oxidized, to volatilize the harmful elements.

Re-dissolve the residue in 1.5 cc. of nitric acid and add to the main solution, and electrolyze in the usual manner. A little more nitric acid and 10 c.c. of ammonia may be added, if necessary, to hold back antimony and bismuth. —*Trans.* A. I. M. E.

Notes on the Metallurgy of Zinc

By E. H. LESLIE*

During the past few months spelter has been the subject of no little discussion. While the unprecedented market conditions have given rise to much speculation as to the future of the zinc industry, the technology of the subject is also being placed under scrutiny and smelting problems are being investigated. In the past, the United States, although in the forefront of zinc-producing countries, has never held a prominent position as an exporter of spelter, the home production being but little in excess of the requirements of domestic industries, so that the foreign market offered no particular attractions to the American producer. Today conditions are changed; the domestic consumer has been forced to close his doors, in a great many instances, on account of the high cost of metal, and the European demand has advanced prices to an unprecedented figure. There is a decided shortage in retort capacity and to meet the demands of the market every effort is being made to increase the efficiency of existing plants.

In presenting these notes it is impossible, through lack of space and fear of triteness, to more than touch upon a few aspects of the subject and point to the experience of some of the representative producers who are doing their share in the development of the metallurgy of zinc. While the practice in different parts of the world varies as to cost and technical details, the information available shows a marked degree of standardization of practice and general uniformity of metallurgical results.

The ores of zinc are generally grouped under blende and calamine, the former being the sulphide and the latter including the more common carbonates and silicates. Since the price of zinc has advanced so astonishingly the smelters have refused to buy ore containing less than 40% zinc, with a preference for the ores and concentrates that are free from lead. High-grade concentrate averaging 51% and upward is in demand, while the 46% concentrate of the Australian mines and the products of lower-grade producers are finding it difficult to find a market, as under present conditions a maximum output of spelter is most desirable. The most deleterious elements, from a smelting standpoint, in ores and concentrates of zinc are lead, iron, manganese, and fluorspar. If the ore contains over 3% lead the latter is distilled in appreciable amounts with the zinc, making it an inferior commodity. The iron and manganese, if in excess, form fusible slags; hence not more than 10% of these elements is permissible in a concentrate. The fluorspar not only forms a very fusible slag, but also deteriorates the lead-lined chambers as employed in the process of sulphuric acid manufacture. The more common minerals of zinc are shown in the following table together with the loss in weight by complete calcination. Comparatively dry ore contains about 10% moisture.

Mineral and formula.	Percentage of zinc.	Percentage of loss in weight by complete calcination.
Blende, ZnS	67.2	16.4
Franklinite $(FeMnZn)O.(FeMn)_2O_3$	21.0	...
Hemimorphite, $2ZnO,SiO_2 + N_2O$	53.7	7.5
Hydrozincite, $3ZnO,CO_2 + 2H_2O$	57.1	24.7
Smithsonite, $ZnCO_3$	52.0	35.2
Willemite, $2ZnO,SiO_2$	58.1	...
Zincite, ZnO	80.3	...

	Lead, %	Iron %
American high-grade spelter contains	0.01–0.02	0.01–0.02
Vieille Montagne spelter contains	0.01–0.02	0.01–0.02
U. S. Western spelter contains	0.4 –1.0	0.02–0.05

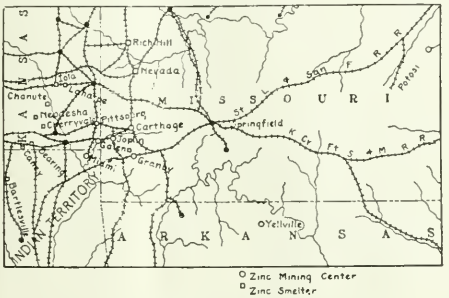
Electrolytic spelter is slightly inferior to the high-grade product. Silesian spelter contains a slightly greater amount of impurities than the U. S. Western brand.

The zinc-smelters of the United States, generally speaking, are lacking in calcining and roasting facilities. In the treatment of calamine hand-rabbled furnaces have been generally employed, and in English practice five men in 24 hours are able to calcine 20 tons of calamine, using 15.1% of Cardiff coal. The loss in weight amounts to 23% of the charge. A mechanically-rabbled reverberatory furnace in 24 hours will treat 12 tons of concentrate, using 12.4% of Cardiff coal and requiring two men per shift. The loss in weight by the mechanical method is about 28%. The mechanical furnaces therefore show a greater efficiency than those that are hand-rabbled. In European practice waste-heat from the distillation furnace is sometimes used for roasting. In treating hard calamine the fuel consumption is equivalent to 10 to 20% by weight of the charge.

Where it is not desired to use the gases from the roasting-furnaces for acid-making, the ordinary type of reverberatory is usually employed. In this connection the Zellweger, the Cappeau, and the Ropp type have found wide application. It is seldom that the gas from these furnaces contains over 2% of sulphur dioxide by volume. These types of furnaces have found wide application in Middle-West zinc-smelters. In Upper Silesia the Hasenclever furnace, which is a hand-rabbled muffle-furnace, has been used generally. Such a furnace with a hearth-area of 300 sq. ft., using 25% of the weight of the calcine of poor coal for fuel, will roast 17¼ lb. per square foot of hearth-area per 24 hours per man. The gas from this furnace ordinarily contains 7% sulphur dioxide. In the roasting operation the sulphur content

*Representative of this paper at Chicago.

is reduced from 30 to 1% with a loss of ¾% of zinc. In Westphalia the same type of furnace with a hearth-area of 325 sq. ft. will treat 17¼ lb. ore per man per day, using 15% of fuel. This type of furnace was built originally with three hearths, each having 12 doors for rabbling, and an ordinary fire-box underneath. Two furnaces are usually built in pairs with a common dividing-wall and are somewhat similar in general construction to the Hegeler furnace.* The Hegeler furnace is generally constructed with seven hearths and has a capacity of about 50 tons per day. The consumption of fuel is about 20% and the sulphur content is reduced to ½ to 1%. These furnaces are mechanically rabbled and particularly adapted to the manufacture of sulphuric acid. The Browne horseshoe furnace has a capacity of about 12 tons per 24 hours and the product contains from ½ to 1% sulphur. This type of furnace has been



SOUTH-WEST MISSOURI.

used in zinc-smelting in the United States, but at present it is not enjoying the same favor as other types of reverberatory. A great many styles of roasting furnace have been developed for use in zinc-smelting, but in large part they may be classified under the ordinary reverberatory furnace and the multiple-hearth muffle-furnace. Mechanical rabbling devices have generally replaced the hand-rabbled furnaces. This is especially true in American practice, the latter type having almost disappeared in zinc-smelting. Many modifications of the old MacDougall furnace have been developed. Among these may be mentioned the Wedge, the Herreshoff, the Hass, the Pearce, and the O'Brien. This type of furnace has been successfully used in the manufacture of sulphuric acid from pyrite, but has not found much favor with zinc metallurgists.

Various types of distillation furnaces have been developed, but all of them belong to what may be considered a type of reverberatory furnace, in which the charge is placed in enclosed muffles or retorts for the distillation of the zinc. The Belgian furnace is generally looked upon as standard and is almost universally employed. The charge is made up of roasted concentrate and fuel, which usually is mixed mechanically. The roasted blende requires from one-half to one-third its weight in fuel as a reducing agent, as does also the calcined calamine. The average charge would contain from 40 to 50% fuel and weigh 60 lb. per retort, although this varies with different types of retort and muffles. While retorts are ordinarily hand-charged, a mechanical device known as the Saeger charging-machine† has been successfully employed for this purpose, especially in Europe, where the arrangement of the furnaces in series has made it particularly adaptable.

In the operation of a distillation furnace, if conducted at a comparatively low temperature, but little lead is volatilized; but in order to get the maximum recovery it is necessary to use higher temperatures, and when the ores contain an appreciable amount of lead it often is distilled with the zinc. A typical charging mixture would be:

	Weight, lb.	Composition, %	
Roasted blende	450	Zn	65–70
Calcined calamine	410	Zn	40–50
		Pb	6– 7
Refuse	140	Ag	0.005 and gangue
Total	1000	Fe	15–18
		S	1– 1½
Coal	400	Ash	9.0
		Volatile	8.5
		Fixed C.	82.5
Residue or cinder	680	ZnS	4.0
		Zn	0.1
		PbO	1.9
		Pb	3.1
		Ag	0.006
		Fe	5.7
		FeS	2.5
		FeO,Fe_2	0.03–15.6
		C	18.1

The zinc loss in Upper Silesia when treating 25% roasted ore is 25 to 35%, while the loss at the Belgian and Rhineland plants, treating 45 to 50% roasted ore, is from 10 to 15%, which is good practice. The residue is generally about 60 to 70% of the weight of the charge and assays from 4 to 7% zinc. In treating ores containing an appreciable amount of silver it has been found profitable to re-treat this residue. The process was developed by the Jones brothers at Bartlesville.‡

The 'blue powder' produced is generally equivalent to 10 to 15% of the spelter. This oxide of zinc is usually re-charged into the retorts. In European practice 'prolongs' are generally used in conjunction with the condensers, but in American practice they have found but limited application. The object of the 'prolong,' of course, is to effect an increased saving by collecting the fume that escapes from the condensers. However, the use of these has certain objections that throw doubt on their real efficiency. Practically all the distillation furnaces today are gas-fired, using either natural gas, where it is available, as in Oklahoma and Kansas, or producer-gas, as is generally used. The direct-fired furnaces have practically disappeared, because a saving in fuel of 10 to 20% has resulted from using producer-gas, and by

*'The Rose Lake Smelter of the Granby Company,' E. H. Leslie, Mining and Scientific Press, September 12, 1914, p. 394.

†'The National Zinc Co., Bartlesville,' E. H. Leslie, Mining and Scientific Press, July 25, 1914, p. 136.

‡'Zinc Smelting at Bartlesville, Oklahoma,' E. H. Leslie, Mining and Scientific Press, July 11, 1914, p. 44.

using a regenerative furnace the saving in fuel amounts to as much as 50% over the old direct-fired furnace. While the modern distillation furnace is far from an efficient device from the thermal standpoint, it is nevertheless, a decided improvement over the old type of furnace.

The distillation process is the most expensive feature of zinc smelting, and has been the subject of no little criticism by metallurgists in other departments. However, no satisfactory substitute for the present retort-furnace has been evolved, although numerous attempts have been made in this direction. Considerable attention has been given to electrolytic recovery during recent years, but it has yet to find a recognized place in the smelting of zinc ores. Generally speaking, the cost of distillation increases as the zinc content decreases. The recovery of zinc improves as the zinc-content in the roasted ore increases, approximately as follows: a roasted concentrate containing 70% zinc on being treated in a distillation furnace under normal conditions will result in an 85% extraction of the zinc and 42% of the charge will remain as residue. Under the same conditions, a concentrate containing 50% zinc on being treated will result in an extraction of 84% of the zinc and 69% will remain as residue. The cost of distillation is a variable one, depending upon the cost and quality of the fuel, clay, labor, and supplies.

On the Continent, the following is a rough summary of the distillation practice. With a Belgian type of furnace, using concentrate + 50%, there is charged about 63 lb. per retort. With a Belgian-Silesian type of furnace, using from 40 to 50% roasted ore, there is charged about 75 lb. per retort. With the Silesian type of furnace, using 20 to 40% roasted ore, there is charged about 225 lb. per muffle.

The coal, retort, and zinc losses at various plants are shown in the following table:

Place.	Coal per ton of spelter.	Zinc loss, %	Retort loss per day, %
Vieille Montagne Angleur	3.5–4.5	15	3.5
Bergen Point, N. J.	7.4	25	7.1 (high Fe)
Passaic, N. J.	5.8	20	6.4
Lehigh Zinc, Pa.	6.2	18	3.7

In European practice the following is illustrative:

Place.	Coal per ton of roasted ore, %	Per ton of spelter, %
Upper Silesia	1.1	...
Rhineland	1.2	...
12 Belgian works	1.65	5.2
Swansea	2.45	5.81
Crown Spelter	...	5.5

Data supplied by Mr. Jones on coal consumed per ton of blende in American practice:

	Tons.
For roasting	0.25
For reducing	0.60
For gas	1.20
Total	2.05

The operation of distillation furnaces at different places, as regards the number of retorts per furnace, and retorts per man-shift, and the retorts per man-maneuver, is shown in the following table, as compiled by W. R. Ingalls:

Locality and firing.	Retorts per furnace.	Retorts per man-shift.	Retorts per man-manuever.
Kansas (direct)	224	19	28
Collinsville (direct)	256	18	26
La Salle, Ill. (producer-gas)	864	27	33
Iola, Kansas (natural gas)	620	29	36
Indiana (natural-gas)	200	26	33
Indiana (natural-gas)	424	22	30
Belgium (producer-gas)	400	22	28
Belgium (direct)	140	18	23

MAP OF OKLAHOMA.

Labor is an important item; it varies materially in different localities. Using direct-fired Belgian furnaces, in Kansas, containing 224 retorts and treating 5 tons of roasted ore per 24 hours, two furnace-men are required at $4.70 per day, two smelter-men at $3.80, four helpers at $1.40, making a total of $22.60 per day. Thus the cost of operation is from $4.52 to $4.71 per short ton. At Iola, Kansas, 21 men-shifts are to be had for $40, the two foremen get from $2.75 to $3 per day and the chargers $2.30 to $2.35 per day.

The cost of roasting and distilling, as estimated by W. R. Ingalls, is shown in the following table and will serve to give a general idea of the cost of operation in different localities.

	A.	B.	C.	D.	E.
Labor	$4.25	$4.52	$4.80	$3.20	$3.24
Fuel	0.80	1.69	0.80	3.75	3.32
Reducing	0.80	0.80	0.80	0.67	0.55
Clay	0.44	0.40	0.44	0.50	0.72
Supplies	0.20	0.20	0.20	0.20	0.20
Repairs and renewals	0.48	0.75	0.41	0.65	0.64
Administration	1.00	1.10	1.00	0.70	0.60
Totals	$7.97	$9.46	$8.45	$9.67	$9.27

A. A well-designed gas-plant (gas at 2c. per 1000 cu. ft.) using mechanical roasters.

B. Well-designed Illinois coal-gas regenerative plant using roasters. Use 2¼ tons of coal at 75c. per short ton.

C. Ordinary Kansas natural-gas plant equipped with roasters.

D. Rhineland, Germany, well-designed hand-roasters, regenerative gas-fired furnaces, coal at $2.50. Uses 1½ tons of coal per ton of ore.

E. Same plant using 1¼ tons of coal at $2.50 per ton.

Cost of distillation in Upper Silesia as summarized by Max Liebig in 1910, is shown in the following table:

	Per ton of roasted ore.
Coal at $2.86	$3.427
Flux coal at $1.90	0.857
Retorts	0.595
Condensers	0.18
Sundry materials	0.236
Tools	0.155
Repairs	0.774
Labor, superintendence, and general expense	2.678
Total	$8.90

It is apparent that these costs are exclusive of mixing and roasting. The cost of labor is said to be about 16.33 marks, which brings the total to 42.32 marks ($10.25). The recovery of zinc was 87 to 89%.

The cost of distillation in Belgium per metric ton of roasted ore as compiled by M. Guillet is as follows:

Coal at $1.95 to $2.40	$2.92 to	$3.41
Flux	0.63	0.73
Retorts	0.68	0.79
Condensers	0.24	0.29
Materials	0.18	0.27
Sundries	0.59	0.67
Total wages	4.49	5.84
Total	$9.73 to	$12.00

The cost of mixing was probably included in these figures. The recovery effected was 84.2 to 92% of zinc. The cost of roasting was not included, and was probably covered by the acid produced. These figures are compiled from the results of the operations at the Angleur, Corphalie, Engis, and Bleiberg plants.

The best practice in the United States, as conducted at two of the largest plants, is shown in the following table, which was compiled by Archibald Jones, manager of the Bartlesville Zinc Co., Bartlesville, Oklahoma.

Roasting Cost Per Short Ton of Blende Concentrate

	Natural gas.	Coal.
Labor	$0.327	$0.428
Fuel	0.852	0.956
Power	0.045	0.060
Repairs	0.116	0.130
Total	$1.34	$1.574

Smelting Costs Per Short Ton of Raw Blende

Mixing	$0.35	$0.35
Furnace labor	3.50	3.85
Fuel	2.036	4.70
Flux coal	1.73	1.73
Clay	0.035	0.035
Retorts	0.90	0.90
Condensers	0.258	0.258
Tools, repairs, etc	0.319	0.319
Total	$9.128	$12.142

The pottery department of the modern zinc smelter is of considerable economic importance and a great deal of care and experiment is devoted to producing retorts and muffles that will stand under the rigid requirements of distillation furnaces. A variety of mixtures have been compounded at various plants for the purpose, and the amount of clay used per ton of calcine treated varies considerably. The chemical analysis of the clay does not form a satisfactory guide as to its utility in the furnace, as the life of the retort is largely dependent upon the method of fabrication. A few representative retort-mixtures are as follows:

Belgium—1 part of coke, 2½ parts of burnt clay, 3½ parts raw clay, 3 parts sand.
Morriston—1 part Belgian clay, 1 part Stourbridge clay, 1 part bricks, 1 part burnt clay.
Rhineland—2 parts burnt clay, 1 part raw clay.
America—1 part burnt clay, 1 part raw clay.

The method of weathering the clay and of pugging it varies at different plants. Upon the care given to these operations depends on large part the service obtained from the retorts. With modern equipment, a hydraulic retort-press of the Mehler type has a capacity of about 250 retorts per shift of nine hours. The retorts, as they come from the press, are placed in drying-rooms that are kept at a temperature of about 110°F. There they remain about 60 days before being used. Before being used in the furnace they are placed in an annealing-oven, where they are kept for about 12 hours and given the final tempering. At some plants the retorts are given a protective coating, but this is not the general practice. The average life of a retort is 35 days.

Condensers are usually made of a composition of ½ clay and ½ crushed old retorts. The material is mixed and pugged in a small mill and subsequently molded in a condenser-machine of the Vannatti type. This machine is usually operated by two men and has a capacity of from 1000 to 1200 condensers per shift. When taken from the machine, they are allowed to stand about 24 hours and are then crimped, placed in the drying-rooms for about a week, and then burnt for use at the furnaces.

The cost of plants in various parts of the world is given in the following table:

Belgium and Rhineland	$14.50	per 2000 lb. annual capacity
Canada and United States	$17–$18	
American practice, using natural gas	$10	Per ton of annual capacity in a plant treating 25,000 tons per year.
American practice, using coal and regenerative	$16–$18	
Kansas, using natural gas	$7– $8	

Sulphuric acid works cost $5 to $6 additional per ton of ore. In Europe, roasting is generally done in a separate plant.

It will be noted that the natural-gas plants are by far the cheapest in that a great deal less equipment is required, owing to the total absence of fuel-handling apparatus, producer-gas plants, and accessories. These plants, however, are not built as permanent structures, as the fuel-supply cannot be depended upon. In determining the cost of a plant there are many important

factors to be considered, chief among which is the site of the smelter. Generally speaking, it has been found to be more economical to transport the ore and concentrate to places where cheap fuel is available; that is, where natural gas is to be found in abundance, or to the coal-fields. The present tendency in America is to build smelters in the coal regions of the East. The natural-gas supplies are uncertain and plants erected in districts dependent upon this kind of fuel are necessarily of a temporary nature.

Within the past year the zinc-smelting situation has undergone considerable change by reason of the War,

leading to the suspension of activities on the part of a great many European smelters, and the consequent increased demand on the American producers. This has resulted in a greatly increased American output, the rehabilitation of inactive furnaces, and plans for enlarged operations on the part of a great many producers. The treatment of the Broken Hill concentrate is one of the problems that has confronted the zinc smelter-men, and a movement was launched last year in London to erect a smelter in England for its treatment. While it was deemed inadvisable to proceed with this project, it is not unlikely that a plant will be erected in England to treat the Australian concentrate formerly smelted on the Continent. An estimate of the cost of treating Broken Hill zinc concentrate in Wales is shown in the following table:

Factors Used in Making Estimate of Treatment Cost

Assays:	
Zn	47%
Pb	8%
Ag	10.5 oz. per ton
Recoveries:	
Zn	85% = 40 units
Pb	60% = 48 units
Ag	50% = 5.25 oz.

Costs

Concentrate at Broken Hill, per ton	$12.66
Transportation to Europe, per ton	9.98
Lighterage at English works, per ton	0.35
Heating coal	3.05
Fluxing coal	1.83
Roasting, per ton of concentrate	1.83
Furnace labor, per ton of concentrate	3.17
Cost of plant, per ton of annual capacity, without sulphuric acid recovery	20.00
Sulphuric acid plant figures, on its own basis, assumed to effect a benefit amounting to half the cost of roasting ore, per ton	0.91
Cost of treating residue, per ton	3.05
Price of silver, per ounce (assumed)	0.49
Price of lead, per ton (assumed)	73.00
Heating coal consumption, per ton roasted ore	1.25 tons
Fluxing coal, per ton roasted ore	0.60 "

The cost of treating Broken Hill concentrate in England or Wales will be approximately as follows:

Roasting	$0.91
Furnace labor	2.92
Fuel	3.80
Flux coal	1.10
Clay and retorts	0.97
Condensers	0.16
Repairs and tools	0.28
Administration	0.12
Overhead charges, including insurance and taxes	0.37
	$10.63
Add cost of concentrate delivered at the works	22.95
	$33.58
Deduct value of the residue:	
Recovery of silver	$2.56
Recovery of lead	3.51
	$6.07
Less treatment	3.03
	3.04
Cost of ⅔ tons of spelter	$30.54
Cost per ton of spelter	$76.34

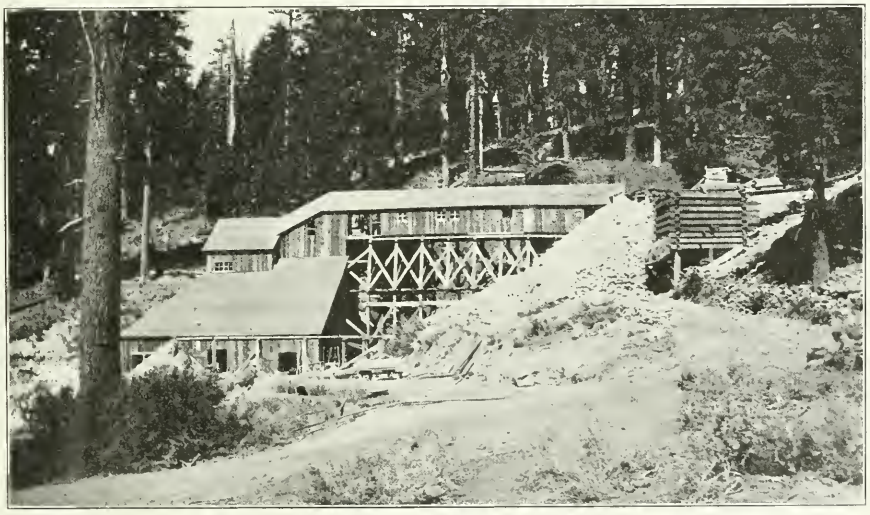
Treating 90,000 tons of concentrate per year at 40% zinc per ton, there would be about 36,000 tons of spelter recovered. At $104.67 per ton the Zinc Corporation balance-sheet shows just about an even break according to the Hirsch contract. With spelter at $104.67, and with a production cost of $76.34 the profit as per the above estimate would be the difference, or $25.93 per ton, and on 36,000 tons it would make a total of $933,480.

In presenting these notes on the metallurgy of zinc, I am indebted to numerous authorities on the subject for a great part of the statistics presented. While I have tried to give credit where due, I would ask forbearance for any oversights.

The Engels Mine and Mill

By THOMAS T. READ

Introductory. The mine and mill of the Engels Copper Mining Company, in Plumas county, California, are among the most interesting to the visiting engineer of any in the United States. The mill is the only one yet built in which no other process than flotation is used for the recovery of copper; the ore deposit exhibits unusual features, as will be described later, and it is extremely instructive to observe how, by mining skill, additional ore reserves have been found, and by the choice of the proper metallurgical method a property that labors under the disadvantage of a situation 26 miles from railroad transportation has been enabled to make a substantial operating profit.



UPPER TERMINAL OF WIRE-ROPE TRAMWAY, ENGELS MINE.

The Mine. The situation of the mining property, at an elevation of 5000 ft. above sea-level, is shown on the accompanying map. There are two groups of claims, aggregating 2800 acres. The Superior group, lying 2½ miles south of the other near a place called the Lower Camp, is as yet largely undeveloped, though the ore found in the outcrop is of higher grade than that found at the surface in the property now being exploited. During the gold rush to California prospectors made their way into this district as early as 1850. Both alluvial and lode mining for gold was done. In 1865 rich copper ore was discovered and a small smelter, which ran intermittently for four years, was built in the Genesee valley.

Copper ore was discovered here by the late Henry Engels some thirty years ago. At that time there was no railroad nearer than Reno, 150 miles away, and mining in such a remote locality was difficult, though a fair tonnage of rich ore was mined from the Superior group of claims and shipped to Swansea. The discoverer and his sons, Henry and William Engels, who have been largely responsible for the later development of the mine, were courageous and persistent, however, and the assessment work necessary to hold the property was so directed as to block out constantly increasing amounts of ore.

The building of the Western Pacific railroad through the canyon of the south fork of the Feather river, in 1909, brought main-line transportation within 26 miles of the mine, and soon after it was decided to construct a 1½-mile aerial tramway and erect a 100-ton smelter at a point at 1800 ft. lower elevation than the mine to treat the higher-grade ores. This scheme proved impracticable, as the mine is in a National Forest, and the company was restrained by an injunction from starting the smelter. Water concentration and shipment of the concentrate is not practicable, as the ore contains too much magnetite. Finally the problem was solved by the construction of a 150-ton flotation plant (now treating over 200 tons daily) that is able to make a 40% copper concentrate from a mill-feed averaging slightly less than 4% copper, the magnetite going into the tailing. Recent

development has doubled the ore reserves and the mine has at once taken a place as a property of unquestioned merit.

The Geology of the mine was studied by G. H. Garrey some years ago for the Engels Company; more recently H. W. Turner made an examination for the Minerals Separation, Ltd., which at that time had the property under option. The result of his study has been published elsewhere*: I have drawn freely on this paper in what follows. Edmund Juessen, the engineer in charge of operations, was kind enough to go with me personally through the workings and point out the significant evidence, so that it was possible to secure in two days a degree of comprehension that would have required weeks of unaided effort and I wish to express my obligation to him.

The important primary minerals in the ore are bornite and chalcopyrite, with associated magnetite. From these minerals the secondary chalcocite and covellite have been derived by upward secondary enrichment, according to the opinion of Mr. Rogers, after microscopic study. Near the surface the ore has been oxidized, chiefly to malachite, though azurite, cuprite, and native copper are also found.

Two rocks are found in the mine, a dark-green one, usually fresh, and a light-colored one that is more decomposed where so far found. The microscopic study by Mr. Rogers reveals the dark rock as a norite-diorite, varying from a fine-grained plagioclase-hypersthene variety to a coarse-grained plagioclase-hornblende rock. The light-colored rock is a grano-diorite, consisting essentially of plagioclase, microcline, quartz, and biotite, the last being variable in amount and often altered to chlorite. For convenience these two will hereafter be referred to as the basic and acid rocks. The ore occurs chiefly in the basic rock, often at a distance from the acid one; it has nowhere yet been found in the acid rock except near its contact with the basic one, and then only in subordinate amount. The microscopic study by Mr. Rogers revealed the ore minerals as later than the associated silicates, but the authors of the joint paper consider that this does not necessarily indicate a time interval of any magnitude, and that the basic and acid rocks and the ore are all differentiation products of a single magma. Since the examination on which this opinion was based exploratory work has resulted in developing double the quantity of ore then exposed and has brought to light fresh evidence that apparently points to the Scotch verdict of "not proven." It may well be true that the three products have differentiated from a single magma, but, in my opinion, the following reasons indicate that further consideration must be given to the possibility that they were in that case differentiated elsewhere and brought into their present relation separately. This would lead to the concept of the acidic rock having intruded the earlier consolidated diorite, and the formation of the orebodies as resulting in some way from this intrusion.

1. The ore is not found in the acid rock except near its contact with the basic one. In the basic rock it occurs near the contact, also along the joint-planes. It is not disseminated throughout the basic rock, which in some places contains no copper and in others exhibits fair-sized bodies of rich ore. Some explanation is necessary for the concentration of the copper minerals in ore-shoots.

2. The physical structure of the acid and basic rocks is markedly different; so much so that in most places a stranger can, after a couple of hours underground, easily perceive whether he is in the one or the other, without breaking a fresh surface, merely by the aspect of the walls. The most striking feature of the basic rock is a nearly horizontal jointing that is so prominent that a casual observer might easily suppose himself to be regarding a sedimentary rock of low dip. Other joint planes at 60° to 90° cause the face to break in a rough blocky way that is quite characteristic. The acid rock does not show this horizontal jointing, it is much more fissured by thin seams of gouge, and veinlets, in which calcite, analcite, and chlorite are present. These are regarded by Messrs. Turner and Rogers as pegmatite. It breaks to a much smoother surface. Where the two rocks are in contact the structure of one does not pass into the other, as shown in Fig. 1.

3. The acid rock is found in wedge-shaped and tongue-like bodies such as might have resulted from its intrusion into the basic rock, but which are less easy to explain as a product of segregation.

4. Where the two rocks come in contact the transition is never more gradual than might be the result of intrusion. On the other hand the relations shown in Fig. 1 can scarcely be regarded as produced by segregation.

5. Development work based on the theory that the ore-body is the product of intrusion of the acid rock into the basic ore has resulted in finding double the amount of ore previously exposed. This argument will naturally appeal most strongly to the mining engineer.

6. The neighboring Superior orebody, which I did not visit, is described by Mr. Turner as consisting of the same ore-minerals in apparently the same rocks, but occuring along joint-planes, and he states (p. 369) that the ores are distinctly later than the country-rock. While this is only collateral evidence, it indicates the necessity for exhaustive study of all the evidence now available before rejecting the hypothesis that the ore at Engels is also later than the rock in which it occurs.

It is thus seen that there are two horns to the dilemma. If these reasons for considering the hypothesis that the ore deposit is the product of intrusion of the acid rock into the basic ore are accepted, it is difficult to explain how the copper minerals could have been introduced without alteration of the silicate minerals having been produced. On page 387 of the paper quoted, Mr. Rogers states: "About the only conceivable way in which the replacement of silicates by the ore-minerals could have taken place and still leave the silicates unaltered is by means of gaseous solutions. The ore-bearing solutions

*'A magmatic copper sulphide deposit.' By H. W. Turner and A. F. Rogers, *Economic Geology*, June, 1914.

were probably rich in mineralizers." And on p. 385 he says: "Chlorite is probably a pneumatolytic mineral. It is an alteration product, but so is the hornblende." The theory of the mine foreman is that where the basic rock is coarsely crystalline and characterized by hornblende ore will be found not far off. These suggestions may perhaps serve to cover this point. On the other hand, if the magmatic segregation theory is accepted adequate explanation must be found for the phenomena noted above. To establish definitely either view further study seems necessary, and the purpose of these remarks is to stimulate discussion of this interesting phase of the subject.

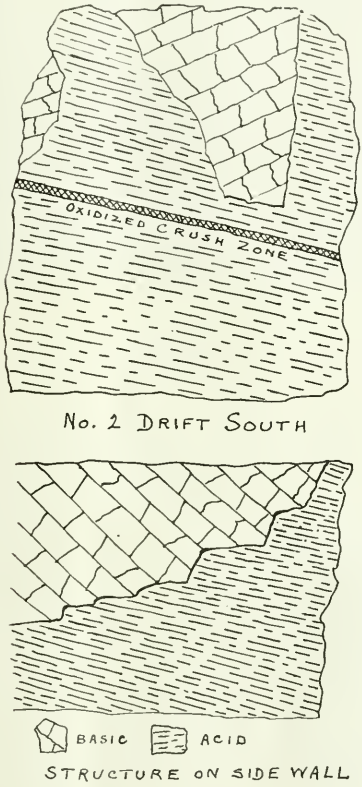


Fig. 1.

The deposit is opened by five adits and a shallow shaft. The lowest adit has a length of 1800 ft., the total length of workings being about 5000 ft. The adits have recently been connected by raises and all the ore is sent to the mill through the lowest. The ore occurs mostly in the basic rock, either paralleling the jointing of low dip, or at right angles to it. The theory of the underground foreman is that when he encounters coarsely crystalline basic rock containing a little chalcopyrite he has reached the foot-wall of the ore. This theory has proved eminently successful, for by turning off in the right direction in the old workings and driving for 15 or 20 ft. good bodies of ore have been found in a number of instances. Development work, including diamond-drilling, now in progress is uncovering considerable quantities of ore.

Near the surface a considerable quantity of oxidized ore has been found, but at present this is not useful as the oxidized copper minerals are not suitable for recovery by flotation. In the later stages of mining operations when larger quantities of oxidized material have been blocked out it may be profitable to erect a leaching plant to treat it.

The Mill, designed and built under supervision of C. B. Allen of the Minerals Separation staff, is on the hillside about 800 ft. southwest of the lowest adit. Horses are used to haul trains of 7 one-ton Koppel cars from the adit to the mill and also to haul the empty cars into the mine, as the adit was driven on a wheelbarrow grade. The cars are dumped into a storage bin of 120 tons capacity, from which it feeds over a grizzly to a No. 5 McCully gyratory crusher, crushing to 1½-in. ring. The crushed product goes to a 16-in. belt-elevator, which discharges into a 200-ton mill-bin. The ore is drawn from this by a Challenge feeder and sent through a trommel having ¾-in. holes. The oversize goes to a set of 36 by 16-in. Superior crushing rolls and the crushed product is returned by an elevator to a trommel, so that all the ore eventually passes through the trommel and thence to a pair of 36 by 16-in. Superior rolls. The crushed product from these goes to a No. 2 duplex Dorr classifier. The

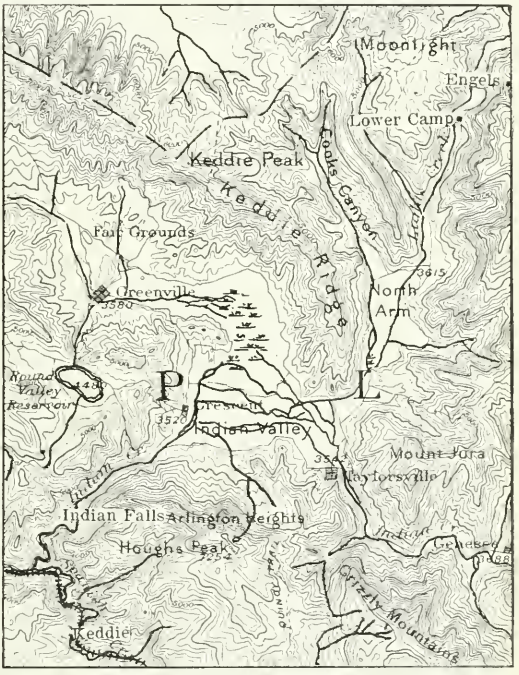

Fig. 2. Map of Engels District.

classifier feeds a 7 by 10-ft. tube-mill, which discharges into the same Dorr classifier, the amount of ore in circulation through the tube-mill amounting to 400 to 500 tons per day, so that the classifier is heavily loaded. The crushing equipment was built by the Power & Mining Machinery Co. The flotation equipment was built for the Minerals Separation Co. by Meese & Gottfried of San Francisco.

The mill-feed averages 3.8% copper and the tonnage treated amounts to 180 to 225 tons per day, depending on the hardness of the ore, as the present capacity of the mill is limited by that of the crushing and grinding machinery. The ore as mined varies a good deal in copper content and the desired average feed is maintained by sending to the bins the requisite proportions of higher and lower grade ore. As in most mines, there is more low-grade than high-grade ore available, the low-grade also being the harder. The capacity of the mill will probably be increased soon and one of the first considerations therefore will be the securing of increased crushing and grinding capacity.

The overflow from the classifier has been crushed to such a fineness that only 5% remains on 100-mesh and 65% of it will pass 150-mesh. This goes to a 12-cell standard Minerals Separation flotation machine. The oil added amounts to 0.4 lb. per ton of ore, half of which is fed to the tube-mill and the remainder to the different cells. The froth from the first three cells is drawn off as a finished concentrate. The froth from the remaining cells is returned to the first cell for re-treatment. The present total extraction averages 84%. The soluble (in dilute sulphuric acid) copper ranges from 0 to 0.4%. About two-thirds of this is recovered, the variation in the amount present leading to a corresponding variation in recovery.

The concentrate froth is sent to a settling-tank outside the building and the thickened froth then goes to an 8-ft. diam. by 6-ft. face Oliver filter, which produces a cake averaging 10 to 12% moisture. As this concentrate has to be shipped to the Garfield smelter, near Salt Lake City, it is desirable to reduce the moisture down to the point (5 or 6%) at which loss by dusting begins to occur. For this purpose an unused drag-classifier is being modified so that a fire can be built beneath it. The dried concentrate is packed into canvas sacks of convenient size to handle and loaded into the buckets of the tramway from a platform built out from the end of the mill. At the lower end of the tramway the sacks are loaded upon trailers drawn by a 75-hp. Holt caterpillar tractor. This hauls them to a transfer station at the edge of Indian valley. From this point to the railroad at Keddie the roads are better and the grades easier, and the transport is effected by Mack trucks, which, of course, travel at a much higher rate of speed than the tractor. At the railroad the sacks are emptied into railroad-cars and the concentrate sent to the Garfield smelter.

As already indicated, transportation is an important factor in the mining operations, and the making of a high-grade concentrate to reduce transport charges is an important item. The success attained by flotation is therefore partly due to the ability to make a concentrate containing 40% copper, as compared with the low-grade product made from this ore by ordinary water concentration. One of the most interesting features is the low cost of construction of the mill, amounting to less than $250 per ton of daily capacity. Through the kindness of E. H. Nutter the detailed figures are given below:

Factory cost of equipment	$22,227
Clearing millsite	101
Grading	1,847
Foundation excavations	164
Concrete aggregate	421
Contract for construction	11,800
Force account labor	244
Sundry labor	223
Sundry building material	24
Rail freight (about)	3,400
Auto trucking (about)	830
Teaming	1,461
Lumber, (148.25 M in place)	1,674
Engineering and general expense	2,716
Total cost	$47,132

Before starting operations, the following additional expenses were incurred:

Operating tools and appliances	$ 495
Operating supplies (oils, pebbles, etc.)	2731
Spare parts	251
Total	$3477

Owing to the fact that the mill equipment was shipped in mixed car-lots with other equipment for the power-plant, charges for rail-freight and auto-transport can only be approximated. The contract covered the cost of all labor employed in erecting the building, preparing the foundations, installing and adjusting all equipment, as well as the cost of corrugated iron roofing, all cement used in the foundations, building hardware, doors and windows, electric wiring material, and structural iron.

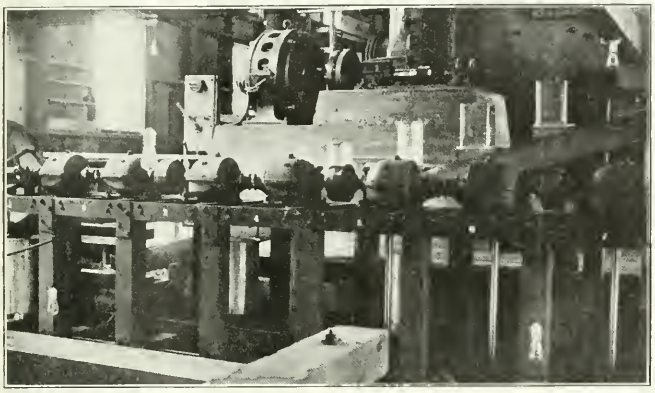
Hydro-Electric Power has been secured by diverting the waters of nearby creeks, which pass through a 4-mile flume to a power-house at the Lower Camp, 2¼ miles from the mine. Here a 485-ft. head is developed and about 450-hp. generated, which is transmitted at 2300 volts over a 10,000-ft. copper-wire transmission-line to the mine. From the middle of August until January the flow is not sufficient to generate all the power required, so two Samson distillate engines are provided for service during that period. The increasing output of the mine makes a larger and more assured source of supply necessary and arrangements have therefore been made to secure direct service from the system of the Great Western Power Co. This will furnish power sufficient for all probable future needs available at a reasonable rate, while the present plant will serve to carry peak-loads and will also provide a reserve in case of interruptions to the power service.

Working Conditions. As will have already been perceived, transportation is an important factor in operations at this property, situated as it is 26 miles from the

railroad and at an elevation of 5280 ft. Fortunately, good roads have been constructed by the county authorities and are kept constantly in repair. To within 2½ miles of the mine the grades are moderate, but in that distance the road climbs 1800 ft. The tramway handles all supplies over most of this steeper portion. I had a good opportunity to see during my visit an exhibition of the skill and ingenuity that are essential to success in all mining enterprises. The frame of an Ingersoll-Rand compressor, to provide additional air for drilling, weighing 13,000 lb., had been brought from the railroad to Lower Camp on a 5-ton Packard motor-truck, one of two that have been engaged, under contract, in hauling the concentrate that was stored earlier in the year. The truck could not proceed up the steep grade from that point to the mine, so it was necessary to transfer the heavy frame from the truck to the trailer of the tractor. The trailer was put into position directly behind the truck, and a similar truck was connected in front by a chain to aid in pulling. The chains holding the frame in position on the truck were loosened and the frame was tied to a convenient tree by a strong piece of wire rope. The two trucks were then started and, the wire rope holding the frame in position, it was gently slid from the truck to the trailer, the whole operation taking only a few minutes. The tractor ascended the steep grade without any difficulty and the frame was safely landed at the desired point.

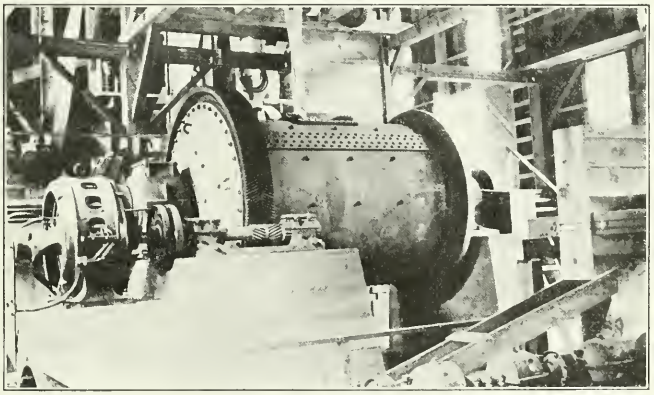
Difficulties sometimes have their bright side. During the rainy season of the early spring the roads were heavy and it was decided to store the concentrate in the smelter-bins, instead of going to the expense of having it hauled to the railroad by teams. In this way about a thousand tons of concentrate was accumulated. Meanwhile the price of copper rose so rapidly that by the time shipment was practicable the value of the concentrate had increased about $35 per ton.

Operations are hindered, as is frequently the case in mining, by the necessity for utilizing structures and arrangements already in place. The tramway connects with the adit above the present working adit, making the delivery of supplies inconvenient. This will shortly be remedied by moving the terminal to the point where the tramway crosses the track to the mill and constructing the storage warehouse and general office at this point. In designing the mill the funds available did not permit the building of storage-bins of the size otherwise desirable for equalizing operations. Underground development has not yet reached the stage where the stopes can be utilized for storage, so that work underground is unduly dependent on the daily fluctuations in the operations of the mill.

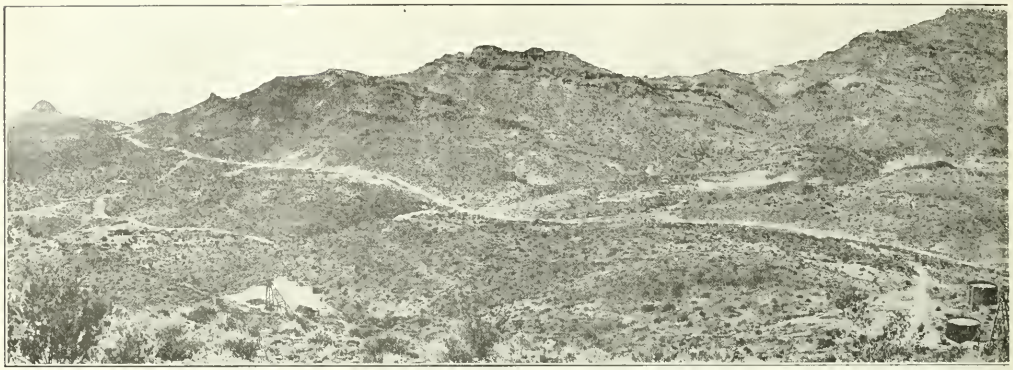


FLOTATION CELLS AND BASE OF TUBE-MILL.

There is abundant supply of timber on all the claims. Yellow and sugar pine, Douglas fir, and cedar trees of good size are at hand. A saw-mill has been erected and all the timber necessary for new construction and mine operations is sawed on the spot. As the property is in a National Forest a small stumpage charge is made for all timber cut for purposes other than the working of the mine itself. The cutting of the timber also serves to lessen the danger from forest fires. Henry Engels is president of the company, Elmer E. Paxton general manager, Edmund Juessen engineer in charge of operations, Henry Hanson mill superintendent, and John Reinmiller mine foreman. To all these gentlemen I wish to express my obligation for many courtesies.



MOTOR-DRIVEN TUBE-MILL.



United Western. Main Road to Gold Road.

PANORAMIC VIEW OF A

The Oatman District, Arizona

By HOWARD D. SMITH*

A recent mining discovery has revived interest in the Oatman district. Therefore some notes gathered during a recent short inspection may be of interest.

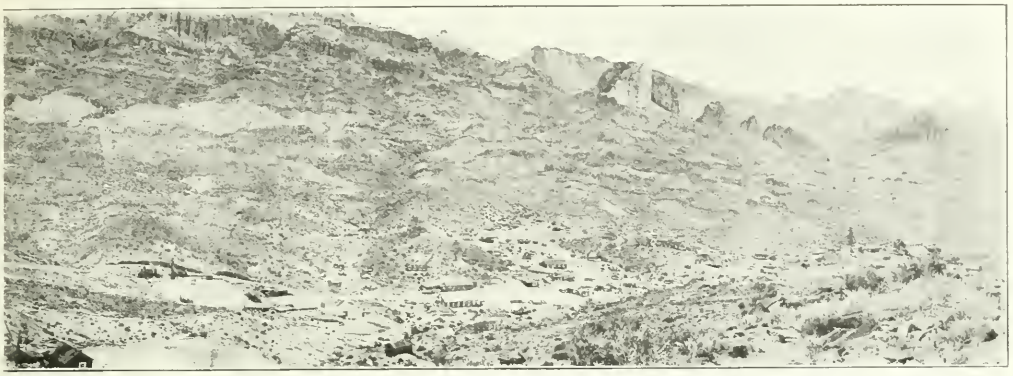
This district is situated in the Black Mountains, in Arizona, but only 20 miles north-east of Needles, in California. Passengers from the west, now that the Colorado river is low, can cross in a launch at Needles and proceed thence by regular motor-service. Heavy freight is hauled from Kingman or Topock, both in Arizona, the first named being the best railroad station for Eastern passengers. A railroad to serve the Leland property, a few miles south-west of Oatman, was constructed in 1903, but what remained after severe floods was hauled away. Even the ties are now being used for timbers in the United Eastern mine. There is little likelihood of this railroad being re-built, as all the ore produced in the district is treated locally and motor-trucks will probably prove economical for freight.

About 1863 John Moss discovered what has continued to be known since as the Moss mine at a point four miles north-west of the Gold Road mine. Some $200,000 was produced shortly after the discovery from a small hole on the surface. This showing attracted prospectors to the district. After the rush of the first-comers, little was done until 1902, when the Gold Road mine was opened up. Shortly afterward that picturesque character, Col. Thomas Ewing, promoted a number of properties. While some rich material was produced, his enterprises on the whole were not profitable. Fresh work is to be done, however, on his Victor and Virgin property, now owned by the Orion Mining & Milling Company.

*Mining Engineer, Kohl Bdg., San Francisco.

The prevailing country-rock is chloritic andesite, occurring both as intrusions and as flows, according to F. C. Schrader in U. S. Geological Survey Bulletin No. 397. This intrudes or overlies an older andesite, which in turn overlies a gneissoid granite. In the north-eastern part of the district, extending toward the Gold Road mine, the chloritic andesite is covered by undifferentiated flows of andesite, rhyolite, and other volcanic rocks. Overlying, and intrusive into the rocks heretofore mentioned, are prominent dikes of rhyolite, and finally more andesite and basalt, both as sills and dikes.

For those without the technical knowledge possessed by the geologists of the Survey, the official report, although highly interesting, is difficult of comprehension. As far as I can ascertain, the miners in the district have got little out of it except the idea that the flows of chloritic andesite would have a maximum thickness of 800 ft. and that, as the veins are not likely to be profitable in the underlying older andesite, the maximum depth for successful exploration would be 800 ft. The reported existence of $20 ore in quantity on the 1075-ft. level of the Tom Reed mine, where the collar and bottom are both in the chloritic andesite, is held to discredit Mr. Schrader. If, however, the chloritic andesite, is considered as an intrusion at this point, which is not unlikely, then this find of ore at 1075 ft. is not out of harmony with Mr. Schrader's expressed views. I hope to gain some additional knowledge at first-hand in the future, but at present I doubt whether the formation of ore-shoots can be shown to be controlled by the particular andesite serving as the wall-rock. As a constructive criticism it might be pointed out that if the learned geologists of the Survey would keep in mind the fact



United Eastern. Town of Oatman. Tom Reed.

PORTION OF THE OATMAN DISTRICT.

that they are writing such bulletins primarily for those without technical advantages, more benefit would be derived from their writings.

In general, the veins are strong, persistent, and readily followed. Some, it appears, have been traced for miles. Widths of over 20 ft. are common. Where a more complete substitution of quartz for calcite is observed, the outcrops have resisted weathering and can be seen for miles.

The prevailing strike is SE-NW, with dips at high angles NE, but occasionally SW. Veins are commonly frozen to the country-rock, and the hanging wall is usually the best defined.

The gangue consists in large measure of altered rock cemented by calcite and quartz. Schrader mentions adularia, a variety of orthoclase free from sodium, as another gangue-mineral. The ore is well oxidized. The value of the ore is due almost exclusively to its gold content. Silver is present in small proportion. According to my information the belief seems justified that more gold is found where the quartz replacement of calcite is most nearly complete. Experience in both the Tom Reed and Gold Road mines indicates that the richest orebodies are found from about the 300-ft. level down to around the 500-ft. level. Below that a marked diminution in richness is noted. While rich quartz is often found near the surface, the masses are usually small and irregular. The presence of vugs and manganese oxide in the upper portions of the veins suggests that leaching may have brought about a secondary enrichment at about the 500-ft. level in the mines.

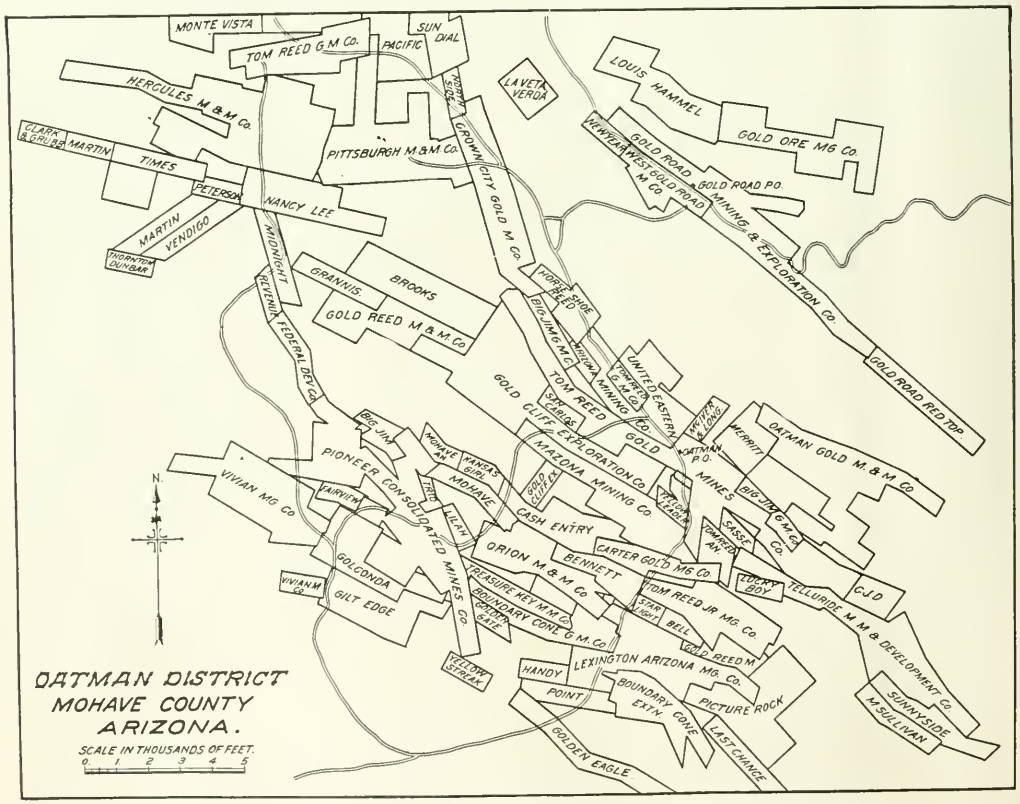
At the present time, the most interesting territory is that shown in the accompanying panoramic photograph. For some years past the Tom Reed company has operated successfully. Three ore-shoots on a vein striking 50°W and dipping 75°NE have been exposed. The workings extend north-west from the main shaft, which is now 800 ft. deep. The longest shoot in the upper levels had a pronounced rake to the north-west, but when followed by a winze about 1200 ft. north-west from the main shaft, the major axis and the north-west limit of the stopes became nearly vertical. This limit is reported to be about 240 ft. south-east of the United Eastern end-line. It may be mentioned that the Tom Reed company heretofore has pursued a policy of secrecy, at least in regard to the underground workings, no visitors being allowed access thereto. The absence of authentic information gave birth to many rumors. Messrs. Long and McIver, then working in the Tom Reed mine, became erroneously convinced, it appears, that the Tom Reed westerly ore-shoot was passing into the ground now owned by the United Eastern. They accordingly obtained an option on this ground, and started a shaft approximately 365 ft. north-west of the Tom Reed end-line. After working slowly for some time, owing to limited means the co-operation of Frank S. Keith and associates was obtained, and the shaft sunk to the 565-ft. level. According to the management, at the 307-ft. level a cross-cut shows 4 ft. of ore assaying $14 per ton; at 460 ft. a corresponding cross-cut 22 ft. long exposed ore assaying $22 per ton, and on the 565-ft. level, the vein shows 22 ft. of ore assaying $35 per ton. On the foot-wall side of the vein on the 460 and 565-ft. levels, there is, in addition, 15 to 16 ft. of material assaying about $3 per ton. On the 460-ft. level about 100 ft. of development north-west on the hanging-wall side has exposed low-grade ore, better ore being found, presumably, on the foot-wall side of the drift, as indicated in the cross-cut. Drifts 28 ft. north-west and 120 ft. south-east on the hanging wall at the 565-ft. level show an average of approximately $50 per ton for the width of the drift. Thus it appears that the concealing of information by the Tom Reed company was a powerful factor in bringing about the development of this promising property. Much difference of opinion exists as to whether the United Eastern vein, with a hanging-wall strike in the south-east drift of the 565-ft. level of approximately N 14° W and a dip 75°NE, is a continuation of the vein exploited by

the Tom Reed company, which has a strike of approximately N 50° W and a similar dip. Going N 50° W from the main shaft of the Tom Reed leads in the direction of the Oatman shaft of the Tom Reed. This, together with the information that a level follows the vein continuously between these shafts, would indicate the contrary. The course followed in the United Eastern workings thus far, provided it persists, will cause an intersection shortly with the Tom Reed workings. The use of air-drills at the United Eastern will hasten the connection suggested.

The property of the United Western is situated about a mile north-west of Oatman. W. H. Weed states that, in his opinion, this is a continuation of the deposit of the United Eastern. A shaft is being sunk a few hundred feet from the eastern boundary of the property. Extensive lateral development is proposed when the 400-ft. level is reached. Mr. Weed expresses the opinion that the geologic evidence is just as favorable for the occurrence of ore as that observed in the United Eastern. It is to be hoped that the venture here will also result favorably.

The Gold Road mine, now operated by the United States Smelting, Refining & Mining Co., is about a mile and a half north of the Tom Reed property. It is included in the Oatman district. The vein, though occurring in the undifferentiated volcanic rock overlying the chlorite andesite, is similar to the Tom Reed as regards width, extent, and character of the gangue. The gold content is lower, however. One of the orebodies cropped strongly, so that large open stopes can be seen for some distance near the No. 1 shaft. Although the metallurgical treatment is similar, namely, crushing in cyanide solutions, without amalgamation, followed by treatment in Pachuca vats and Dorr thickeners, the color of the Tom Reed tailing is much darker. This indicates a difference not apparent in the untreated ore. It is interesting to note that Dorr thickeners appear to be particularly suited to conditions in this district, where little silver is present, weak solutions are used, and slime settles quickly.

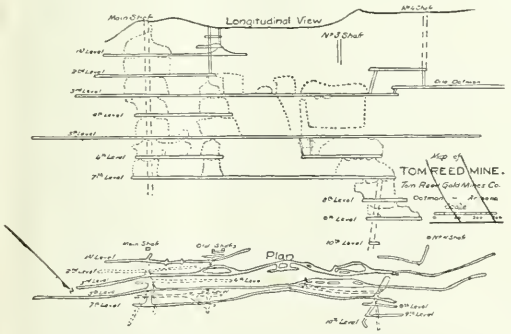
The old Moss mine, where the original discovery was made, is now to be developed under option by the owners of the Gold Road mine. A mining boom now being well under way, development is proposed and is actually being started on many other properties. Oatman itself has outgrown, almost overnight, its site in the vicinity of the mining plant of the Tom Reed property. A new town, Old Trails, located a little over a mile down the *arroyo*, is projected. A wide avenue in the dry bottom is already



MAP OF CLAIMS IN THE OATMAN DISTRICT. PREPARED BY HAFF & COLWELL, LOS ANGELES.

cleared of rocks. The district, to one familiar with boom camps, has a subdued air, particularly after dark. This quiet may be credited in part to prohibition. Let us hope that the energies formerly so prodigally wasted in dissipation will here be expended on actual work underground. A touch of human interest was given to the daily work of Oatman by the coming of Joe Parrizo with two motor-loads of relatives. He had recently received a payment for his interest in what is now the United Eastern property, and insists on having his relatives, whom he had not seen for 20 years (so the story goes) enjoy his success with him. Thus even prohibition does not wholly kill the romance of mining.

Many other properties are either doing development work, or propose to do so. No other bodies of material sufficiently valuable to justify the erection of a treatment plant are known to exist besides those already mentioned. The local slogan is "Gain depth," the inference being that this will ensure finding a mine. The United



PLAN AND SECTION OF TOM REED WORKINGS.

Eastern is instanced as conclusive evidence on this point. As against this, it may be mentioned that development on the United Eastern is at present limited, and the experience of the Tom Reed may be repeated, which followed with a stope to within fifty feet of the surface, a shoot discovered at depth. Further, there is the fact that a considerable number of shafts have been sunk, in some cases over 500 ft., without success. Inadequate lateral development therefrom is reported, however.

The problem in this district is not so much the finding of veins, as the discovery of ore-shoots in them. Nothing sufficiently tangible was brought to my attention to use as the basis for a theory to guide operators in the search for ore. That considerable areas in the veins without ore must be expected is certainly to be inferred from experiences in the Gold Road and Tom Reed mines. Consequently, sufficient capital should be provided for adequate lateral exploration before shaft-sinking is started. It remains to be proved whether the large amount of work now under way in the district will demonstrate that there are signs sufficient to make the successful search for ore something more than a fortuitous gamble.

Copy of a Contract for Tin Ores Between European Smelters and Bolivian Miners

DG
Copy.

TERMS OF SALE OF A. & C. TIN ORE FOR ACCOUNT OF MESSRS. ABELLI & Co.

The whole of the shipments of Bolivian Tin Ore to your consignment of the mark:

A. & C. A. to the extent of about 80 (eighty) tons monthly during the months of March–August, 1914, both inclusive, without guarantee of quantity.

Sellers to have the option of supplying any shortage in any month from surplus shipments in subsequent months, provided such shipments are made not later than the last months mentioned in the preceding clause. Bill of Lading date to be decisive as to the period of shipment.

The maximum quantity tenderable under this Contract is 576 (five hundred & seventy-six) tons, say 96 (ninety-six) tons per month per six months.

WEIGHING, SAMPLING, AND DELIVERY in bulk in ore-yard. Liverpool, at Sellers' expense.

TIN ASSAYS TO BE EXCHANGED by same post, to two points of decimals, and agreed between buyers and Mr. A. H. Knight, Liverpool, acting for Sellers. Should these results differ to the extent of more than half of one per cent, then either Buyers or Sellers to have the option of claiming non-agreement, and a reference sample to be sent to either Messrs. W. H. Christoe & Sons, Truro, or Messrs. F. Claudet, Ltd., London, and their result taken as final if between the results of the original assays, but if otherwise then the original assay of either Buyers or Sellers nearer thereto to be taken as the agreed assay, losers paying cost of reference.

MOISTURE LOSS to be also agreed between Buyers and Mr. A. H. Knight, on sealed bottle samples drawn at time of weighing.

TIN PRICE REGULATING THIS CONTRACT to be the Mean of the Cash and Three Months official prices of Standard Tin, as quoted by the London Metal Exchange on the market days comprised in the period of 14 (fourteen) days following the day on which each steamer bringing Ore under this Contract is reported in Liverpool Customs Bill of Entry.

Broken prices to be regulated and agreed as follows:

2s.6d.	and under	7s.6d.,	5s.
7s.6d.	" "	12s.6d.,	10s.
12s.6d.	" "	17s.6d.,	15s.
17s.6d.	" "	2s.6d.,	20s.

ORE PRICE TO BE ARRIVED AT by the agreed produce of Tin, after deduction of unitage allowance as per following scale:

74% and over	2.00	units	64% and over	3.40	units
73% " "	2.125	"	63% " "	3.55	"
72% " "	2.25	"	62% " "	3.70	"
71% " "	2.375	"	61% " "	3.85	"
70% " "	2.50	"	60% " "	4.00	"
69% " "	2.65	"	59% " "	4.15	"
68% " "	2.80	"	58% " "	4.30	"
67% " "	2.95	"	57% " "	4.45	"
66% " "	3.10	"	56% " "	4.60	"
65% " "	3.25	"	55% " "	4.75	"

being multiplied by the agreed price of Tin, and divided by 100. The result thus obtained is subject to a further Returning Charge of £6 (six pounds) per ton of Ore assaying down to 60%, plus 2s.6d. (two shillings & sixpence) for each unit below 60%, and pro rata for fractions of a unit, down to a minimum assay of 55% Tin.

PENALTY. Should Antimony, Copper, and Bismuth contents combined of any lots exceed ¼%, Sellers to allow Buyers on such lot or lots 2s.6d. (two shillings & sixpence) per ton of Ore, net dry weight for each one-tenth of one per cent of Antimony, Copper, and Bismuth combined in excess of ¼%. Total contents of Antimony, Copper, and Bismuth combined not to exceed ¾%.

STRIKES. In the event of differences with Workmen, Accidents to Machinery and interference caused by Revolution, Insurrections, or intervention of Constituted Authorities, or other contingencies beyond control of Buyers or Sellers, hindering Sellers from delivering or Buyers from receiving or smelting deliveries under this Contract shall be suspended during such time on written notice being given of such inability to deliver or receive by the Contracting Parties, when Sellers shall have the option of withdrawing any Ores so affected and disposing of them elsewhere.

FIRE INSURANCE. Should delivery not have been taken within 14 days from last day of landing at Liverpool, Fire risk to be for Buyers' account. Contract to be canceled for any material damaged by Fire within the time when the Fire risk is for Sellers' account.

SHOULD STEAMER BE LOST. Contract to be void for the portion carried by that steamer, but should the Ore, or any portion thereof be saved and come forward for Sellers' account, Contract for such portion still to hold good.

PAYMENT. Say 90% of the approximate value to be paid in London against delivery order on the day the Ore is sampled in Liverpool, and balance on settlement of assays and receipt of Invoice.

ANY DISPUTE on this Contract to be settled by arbitration, in accordance with the Rules and Regulations of the London Metal Exchange.

London, 17th March 1914.

These ores are of medium quality. They have not been roasted nor treated through magnetic separators.

THE ACCURATE DETERMINATION of radium in radium-bearing ores is generally conducted by the emanation method. With proper care the method is both certain and delicate. It is based on the fact that the gaseous disintegration product of radium, the emanation, can be completely separated from radio-active materials, and that the equilibrium quantity is proportional to the content of radium. The minute quantities of radium emanation concerned in quantitative determinations of this kind are capable of exact measurement by electrical methods, according to H. Schlundt, in *Radium*. The emanation is introduced into an air-tight electroscope or an ionization vessel connected with an electrometer, and the saturation current produced, under proper conditions, is proportional to the quantity of radium in the specimen from which the emanation was separated.

ACCIDENT RECORD at the Anaconda company's mines in the year ended March 31, 1915, was as follows: there were 1,697,814 shifts worked, during which there were 185 accidents incapacitating men from working for a period of 30 days or over. This works out at 10.896 per 100,000 underground shifts.

Concentrates

Readers of the Mining and Scientific Press are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

Three properties desirable in a wire-rope are strength, toughness, and flexibility.

Cedar blocks, on end, have been laid in a 2600-ft. sluice-box at Round Mountain, Nevada.

Three-quarters of a horse-power per ton of ore treated is all that is required at the Alaska Gastineau mill at Juneau.

A kink in a wire-rope can never be taken out. The life of a rope can be greatly lengthened by the use of a proper lubricant.

Pneumatic tools should be part of every mine equipment. So should thermit for welding, and an oxy-acetylene blow-pipe for cutting steel.

Balata, used in canvas belting, is the milky latex obtained in the same manner as rubber, by tapping trees, in the Guianas and Venezuela, South America.

Timbers framed into mitred sets with beveled surfaces are not suitable for use underground, as it is impossible to block them rigidly enough to stand the shock of blasting.

Celluloid is one of the strongest artificial materials, possessing a tensile strength of 10,000 to 12,000 lb. per square inch. It consists of a mixture or solid solution of cellulose nitrate and camphor.

Lead-wool has several advantages over cast-lead in making joints in pipes. It is more quickly placed in a joint, a fire being necessary to melt the pig-lead. On big jobs a pneumatic-hammer is best for caulking.

Electric furnaces generally use the heat of the electric current at an efficiency of 4 to 10 times the efficiency with which the heat generated by fuel is utilized, so that a comparison on the basis of thermal units is not exact.

Air-compressors make a greater output in winter than in summer. Water-jackets on air-compressors sometimes become coated with sulphate of lime from the circulating water, especially if the water gets considerably heated. By washing out the jacket with hydrochloric acid, the scale will be removed.

Zinc oxide, besides its use in paint, is employed in the making of enamels, the manufacture of rubber, the fabrication of linoleum and oil-cloth, the manufacture of printing inks, and in making toilet-powder and pharmacists's preparations. For most of these purposes oxide prepared by the French process is preferred.

Metal roofs are more easily applied and the first cost of installation is, therefore, considerably lower than that of any other type of permanent roof construction. This prevents the passage of flames from below and thus will for a considerable time retard the spread of a fire started from within.

Miners in danger are often resourceful. At Cripple Creek some time ago, John Laughlin saved his life in spite of an explosion of 86 sticks of dynamite within 20 ft. of him. He lay flat on his stomach and hung his head and shoulders down a winze while 19 holes went off. He was almost buried with rock, but extricated himself, walked to the shaft, rang for the cage, and went to the surface. He was uninjured.

Weight is often overlooked in designing a roof. This is an important advantage of tin roofs. For instance, 100 sq. ft. of IC tin laid with standing seam weighs about 65 lb. as compared with 400 lb. for wooden shingles, approximately 400 lb. for 3-ply slag, 500 lb. for 4-ply slag and 650 lb. for slate. Thus it can be readily seen that the lower cost due to lighter construction necessary in the frame-work and supporting walls to bear a sheet metal roof must be taken into consideration.

Purity of Lake copper, according to geologists, varies somewhat with the position of the lode in the series of interbedded igneous flows and conglomerates, which make up the Keweenaw series. Lodes near the base of the series seem to contain more arsenic and impurities than lodes higher up, (the dip of the Keweenaw series varies from 30 to 70°) as though the impurities had tended to settle. Another factor making for impurities in a lode is cross-veins, as in the Mohawk mine.

Mine foundries are a source of accidents. Men step into hot metal in pig molds when they are arranged on the floor; also open sand pig-beds. The turn-over mold, fitted to a stand, lessens danger from this source. To prevent any material being thrown upon a man repairing a cupola, a screen of heavy wire is suspended above him, just fitting the upper part of the furnace. A shield of sheet or cast iron, hinged to the slag-spout frame of a cupola, prevents slag from splashing over the furnacemen. Safety goggles, foundry leggings, and boots should be worn for protection against molten metal.

Sublimed sulphur is obtained by heating the crude material in hermetically sealed retorts, and condensing the vapors in large air-tight chambers. Some of the sulphur is deposited in these chambers in a finely divided state, which form is known as flowers of sulphur. The lightest and best flowers are obtained in the part of the chambers farthest away from the vapor-inlets. The proportion of this grade being small, such sulphur commands the highest price. The test of fineness in sulphur, especially of the sublimed, is its bulkiness. The more finely it is divided, the larger the space a given weight of sulphur will occupy. Flowers of sulphur should not be confused with flour sulphur.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

NOME, ALASKA

Nome Today.—Automobiles, Dredges, Lode-Mining, Tungsten, Cinnabar, Platinum, and Beach-Miners.

The Nome of 1915 is not the wild and wooly mining camp of 1899 and 1900, when the second stampede of the Klondykers from up-river points and the States, rushed into the adjacent creeks and crowded Nome beach for 20 miles with every kind of mining device. The 'chechaco,' or new-comer, who arrived by steamer from the outside this spring, found a quiet municipality free from gambling-halls, hurdy-gurdys, and quasi-amusement resorts. In fact, excepting the ordinary saloons, which constitute about the only meeting-places for those who come to town for business purposes, the 'lid' is down, secure and tight. But there is a hustle and bustle of trade apparent in the open stores and on the streets that gives the Nome of today a thorough business aspect. Stores are open from 6 a.m. to 10 p.m. and why not, since it is daylight. At this time of year the sun is always visible, making almost a 24-hour day. Busy autos and delivery wagons are about all the time, and not uncommonly, even at midnight, one can see heavy freighters moving machinery, lumber, and supplies out to the mines of the interior.

DECEMBER 21 (SHORTEST DAY) AT NOME; SUNRISE, 10:25 A.M.; SUNSET, 1:35 P.M. THE WHITE SPOTS SHOW FIVE POSITIONS OF THE SUN DURING THE DAY.

The first automobile appeared at Nome in the spring of 1904, when malamutes and reindeer beat a quick retreat. Today nearly a dozen autos may be always seen 'honking' their way through Nome's busy thoroughfares. Even in winter, with dreaded blizzards and snow, we are told of 'spoony sourdoughs' who catch tom-cod and seal to take to their squaws in an automobile. The efficiency of automobiles in this region of the vast north land, like the jitneys in the States, has here been proved, having actually supplanted the Arctic and Seward Peninsula railway, which suspended all traffic in 1910. Government road-building throughout the interior has paved the way for automobiles, caterpillars, and traction-engines, while 75 miles of railroad have gone into decay and disuse.

Development of the vast resources of Seward Peninsula however, has continued and where railways have stopped other means of transportation have kept up communication between coast and interior. The output of minerals also keeps steadily growing. Evolution from the individual miners with pick and pan, long-tom and rockers, to hydraulic-mining methods marked the periods of work from 1899 to 1910. About that time, after millions had been spent in ditches and dams for water-storage, developments disclosed a condition that foretold another change, because of uncertain summer rains. Then came dredges, and today there are about 50 of these machines working in the region. Thus the gold content of a great area of virgin territory is being steadily developed.

While the change from hydraulic mining to dredging has somewhat reduced the population, as one of the boats with eight men will handle more gravel than 150 men with shovels, it is a fact that this summer there are more beach miners than any time since 1900. For 10 miles west of Nome there is a continuous line of surf-washers, long-tom operators and sluicers, all intent on making a 'grub-stake for next winter.' The faces one sees at this work along the coast both east and west from Nome, are with few exceptions, old-timers who came in years ago and failed to make their 'piles,' so the beach affords the most inducement for remuneration, and a temporary grub-stake for winter pospecting.

The next natural phase of Alaskan mining evolution is one of quartz development, which already has received a surprising impetus. For several years placer or stream tin has been produced from sluicing operations on Lost river, and the creeks adjacent to Cape York, Tin City, and tributary to Port Clarence. A recent U. S. government report cited the fact that in 11 tons of supposedly high-grade tin concentrate, there was discovered a large proportion of tungsten. Investigation later has revealed the source of these placer deposits to be in the surrounding hills which are of granitic-schist formation. The ore is wolframite, and early development of the deposits is said to be progressing favorably. From Twin Mountain, about 15 miles from Nome, come reports of scheelite placers, associated with gold.

A recent U. S. government report cited the fact that in 11 tons of supposedly high-grade tin concentrate, there was discovered a large proportion of tungsten. Investigation later has revealed the source of these placer deposits to be in the surrounding hills which are of granitic-schist formation. The ore is wolframite, and early development of the deposits is said to be progressing favorably. From Twin Mountain, about 15 miles from Nome, come reports of scheelite placers, associated with gold.

In the windows of Nome's leading hardware-store is displayed a ton of steel-gray graphite. This comes from the Sawtooth range about 30 miles from Nome. It is accessible only in winter by teaming over the ice.

Cinnabar deposits along the Kuskokwim river, first reported in 1904, are also receiving some attention this summer. Two outfits have gone there for systematic development. Some of the ore is rich in mercury. At Topkok, about 55 miles east of Nome, come reports of native quicksilver which is said accounts for amalgam found in virgin ground tributary to Daniels creek.

From the Kougarok river, about 70 miles north of Nome, and once the terminus of the Seward Peninsula railway, are exhibited several large samples of telluride associated with pyrite.

An immense deposit of hematite has been discovered on the plateau above the mouth of Cripple river by a former assayer of Nome. Several engineer's have examined these deposits, but their accessibility is so unfavorable that considerable road construction must be done before the ore can be transported to tide-water for shipment. The present cost of fuel and labor for reduction at the mines is almost prohibitive.

In many clean-ups of the beach-sand and gravel are found traces of platinum. No special effort has apparently been made to save this metal. Like stream-tin, the concentrate is shipped to the States without the platinum being taken into consideration. The source of this platinum is occupying the attention of at least three prospecting parties who are now in the country.

Governor J. F. A. Strong and wife visited Nome on July 7.

GOLDFIELD, NEVADA

The Silver Crown (Stimler) District Development.—New Shoot in Atlanta.—Booth, Sandstorm-Kendall, Kewanas, Great Bend.

The attention of local mining men has been attracted to the Silver Crown district, formerly known as Stimler, situated 50 miles west of Goldfield. Good-grade ore, containing gold and silver in approximately equal value, has been discovered by lessees at a depth of 75 ft. at the property of the Cottonwood Cañon Mines Co. The incline shaft of the Wheeler-Watson lease has been sunk 75 ft. on the vein and a drift has advanced 60 ft. along the footwall, in ore that has lately been yielding average assays about $80 per ton. The district has been but little prospected. Some eight years ago it was the scene of a small stampede, but the little amount of work then done was devoted to searching for high-grade gold ore near the surface. One shaft was sunk to a depth of 450 ft., but was started at the outcrop of the lode. It is a vertical shaft, and no lateral work was done. The district covers an exceedingly rough mountainside, with deep canyons and precipitous bluffs. The walls of the canyons show many veins, offering favorable opportunities for working by means of adits. Although a few locations have been made lately, a large area, containing many of these exposed veins, remains open for location. At several places in the main gulch, adits could be driven to gain depths on the veins of from 100 to 400 ft. in a short distance. There is sufficient water in this gulch for 20 stamps or more during the dryest season. The country-rocks are granite, shale, dolomite, sandstone, and some silicious porphyries. Each is present in large masses and showing little fault disturbance. The Wheeler-Watson vein is readily traced by outcrops for over eight miles, and a number of parallel veins are equally persistent in continuity. F. A. Wheeler and C. W. Watson, the lessees, are planning the early building of a mill. They have located water in the canyon, and this can be brought to the mill-site by gravity. The ore is a white, translucent, friable quartz. Tests indicate that it can be treated at low cost. There is ample wood for domestic use and excellent spring water in the canyon. The latter contains many large cottonwood trees, and piñon-pine timber for stulls can be obtained within a mile or two. The camp is 16 miles from Blair, from which point a branch railroad connects with the Southern Pacific. Some exploiting by 'wild-catters' in the early days, following the discovery, gave the district a bad name, but it now seems destined to make good.

A discovery that is regarded by A. I. D'Arcy as important, has been made on the 1660-ft. intermediate level in the Atlanta mine, and over 300 ft. south of the workings from which the main stope was opened, near the Grizzly Bear boundary. Stoping is now in progress on the new shoot, which assays from $35 to $41 per ton for the width of the drift, 5½ to 6 ft. Almost the entire metal content is gold. This ore is nearly above the point where 6 ft. of $27 ore was exposed by the first cross-cut that penetrated the vein on the 1750-ft. level. The Atlanta and Florence companies have entered into an agreement, the terms of which provide that the Florence shall work through the Atlanta workings, on the 1750-ft. level, to develop its territory, and in return the Florence will grant a side-line agreement to the Atlanta. This will benefit both companies, as it will materially reduce the overhead expense of the Atlanta and will result in important economies for the Florence.

New work has just been started at the Booth, on the 350-ft. level, to explore the vein north of the shaft, in virgin ground. ——The winze of the Sandstorm-Kendall has been sunk 100 ft. below the 500-ft. level, on the incline of the vein, and is yielding assays up to $70 gold, but no commercial body of ore has been found, the rich material appearing only in narrow seams. ——The Kewanas is developing on the 840-ft. level, where the latite-shale contact is being explored.——The Merger is making good progress in driving its east drift at a depth of 1775 ft., following the shale, and A. I. D'Arcy hopes to find the extension of the Jumbo Extension ore within the next 100 ft. A raise and cross-cut will be driven shortly to make a much-needed air connection between this drift and the 1017-ft. level of the Jumbo Extension.——Great Bend has nearly completed the unwatering of the main shaft.

LONDON

Mexican Companies and Their Troubles.—Metal Market.—Tin and Tin Geology.—St. John del Rey.

Mexican news is read with keen interest in London despite the distractions of the great war. Reports of various Mexican mining, railway, and industrial enterprises in which British capital is concerned for the past year are now being made public. They tell a uniform tale of disaster with no hope of relief except as order may be established from outside. Even the companies that have done best in Mexico, all things considered, have enough of which to complain. Santa Gertrudis has succeeded in making one shipment of bullion recently, and has got in a limited amount of supplies. The mill is, however, running at less than half-capacity, and with no certainty as to the future. La Fé has been abandoned to the Mexican staff and no reports are received at London. Buena Tierra has been unable to do much on account of lack of men and transportation. Mr. Bayliss' remarks at the meeting of June 30 may be quoted as typical: "The condition throughout the year was one of utter demoralization. During the months of January, May, and June we were to all intents and purposes dispossessed of our property, and nothing was done. In July and September we were only able to ship 284 and 393 tons, respectively, to the smelter for treatment. In four other months of the year our shipments did not reach 2000 tons; and in no instance have we been able to dispose of the 4500 tons per month which the smelter company is under contract to receive. During the whole of the period labor of any sort has been difficult to obtain and very inefficient. Transportation by rail has been suspended for long periods, and it has been impossible to secure a constant delivery of supplies to the mine; and even when we have been successful in filling our requirements, coal and other commodities have been commandeered by the Constitutional and other forces. On the top of all this the general economic condition of the country has been deplorable, and the rate of exchange has now fallen from the normal rate of two shillings (48 cents) to something like three to four pence (6 to 8c.) as the value of the Mexican dollar, and it is purely nominal at that." Despite all this the staff has stuck to the mine and has been busy developing additional ore reserves though as Mr. Bayliss says "one sometimes feels that it is useless" when it is only possible to sell in "driblets" from the 300,000 tons already waiting to be taken out. The year closed for this company with a profit of £5908 in the place of the £40,000 that might reasonably been expected under normal conditions in that any profit was shown.

The American metal market has also been watched with the greatest interest in London. The phenomenal rise in price of the principal base metals has been very disturbing to local industry. As in the United States galvanizing plants have been largely forced to suspend production because of the high

price of metal. Another and more serious factor is the shortage of skilled labor. This affects all the metal trades and industries and until recently there were even munition plants that could not be operated at capacity for want of men. Correcting this particular evil has, not unnaturally, left other trades in even worse condition for the moment. Sellers of base bullion have been notified that no more lead can be desilverized and this was one factor in the recent rise in the price. In general, it is felt locally that while there is undoubted shortage in metal, prices have been manipulated in America and, in part, with the deliberate purpose of placing the Allies at a disadvantage. The tendency towards lower levels manifest late in June was welcome. Tin is a metal that has been affected less than might have been anticipated and until substitution of one metal for another goes farther prices seem fairly stable. The local trade papers have commented severely on the fact that large contracts for tin-plate have been going to American manufacturers at prices materially lower than those of Welsh tin-plate makers. The announcement too that the A. S. & R. Co. will erect a tin smelter in New Jersey for Bolivian concentrate, has seemed to presage changes. While Straits tin is considered necessary in the manufacture of tin-plate, it is not certain that resolute experimental work would not show this to be a fallacy and at any rate the proportion of the metal used in making tin-plate is much smaller than commonly assumed, being in fact but 15% of the total production. The Cornish tin mines are in a bad way owing to the increased costs and labor shortage. It is quite possible that many will not be able to keep up production and the great war may possibly end Cornish mining on a large scale. In the Malay States tin mining has not recovered from the effects of the fall in price of last autumn. Many Chinese have gone home, leases have been abandoned, and new capital is of course unavailable. Incidentally it may be mentioned that there is a new view, or rather a return to old views, of the origin of Malayan tin. At a recent meeting of the London Geological Society, W. R. Jones of the Geological Survey of the Federated Malay States, presented the results of three years study of the Kinta valley. He totally disagrees with J. B. Scrivenor who, it will be remembered, believed the tin-bearing beds to represent ancient glacial deposits and correlated them with the Gondwana series. Mr. Jones presents strong evidence that they were in fact merely the metamorphosed and weathered equivalents of ancient phyllites and that all, in place of part of the tin, owed its origin to the nearly Cretaceous granite. His paper was accepted as conclusive by the geologists present including Watts, Tellus, and others. It seems likely that his hypothesis, which greatly limits the area of possible tin-bearing ground, will hereafter guide prospectors.

That evergreen mine, the Morro Velho, of the St. John del Rey, in Brazil, has just issued a yearly report showing that the orebody still responds handsomely to the efforts of George Chalmers and his staff of engineers. Developments on the 18th horizon, 5226 ft. vertically below the outcrop, indicate no sign of impoverishment with depth. The internal shaft 'G' has been sunk 600 ft. lower, to 5826 ft., and cross-cuts are being driven toward the lode simultaneously at 5526 and 5826 ft. Until the orebody is proved at these horizons, it is hardly permissible to say that this gold mine is 5826 ft. deep, for until that time arrives, the workings below the 5226 ft. horizon are merely the proverbial 'holes-in-the-ground.' A cheerful aspect is given to the operations by the fact that scarcity of labor no longer harasses the manager, and that it has been possible to keep the output and development at the normal level. Thus during the 12 months ended February 28, 1915 the tonnage milled was 191,500, compared with 174,000 the year before. The yield per ton remains practically constant at 47s.7d. ($11.42). Revenue was £455,927, and £64,262 was distributed as dividend, being at the rate of 10% on both preference and ordinary shares. In addition, £60,000 was transferred from profits to capital account. Many American engineers wonder that so small a proportion of the revenue is available for dividends. The chief reason for the high cost is the arrangement of internal shafts and connecting levels. This method of development was devised by Mr. Chalmers when he undertook the position of manager in 1888. Before his time the workings had collapsed and the problem of re-opening presented many difficulties. Subsequently when the workings were down to 3000 ft., the grade of the orebody fell seriously and the prospects at depth were not sufficiently hopeful to warrant large capital expenditure for the re-arrangement of the system of development. Another factor in high costs is due to the undependable nature of the walls, entailing careful rock-filling. Moreover, the nature of the ore gives metallurgical trouble, as the gangue is largely arseno-pyrite and pyrrhotite. Amalgamation is impossible and roasting too wasteful of gold. In spite of these disadvantageous conditions the recovery is as high as 93%. At the present time ore is being drawn from all the levels between 3424 and 5226 ft. The ore reserves above the latter level is sufficient to supply the mill for 3½ years. For a long time the limit of profitable or possible working at depth has been the subject of study. The immediate factor, beyond the persistence of the ore, to be taken into account is the temperature of the workings. By an elaborate system of measurement of rock-temperature, and fall in air-temperature after ventilation currents have been flowing for a short time, Mr. Chalmers is lead to expect a rock temperature of 116°F. at horizon 22, or 6426 ft. vertical, and an eventual air-temperature of 95°F. This lowering of the temperature involves the cooling and drying of the incoming air, and the subdivision of the currents so that the same air shall not pass through too many stopes in series. It should be remembered that the average temperature of the outside air during the hot season is 75°F. so that its power for cooling is small. The effectiveness of artificially cooling the incoming air appears therefore to be considerable. Altogether the St. John del Rey promises to give interesting studies relating to the limit of endurance of the miner in depth.

CRIPPLE CREEK, COLORADO

Ella W., Molly Kathleen, Vindicator, Mary McKinney, Independence.—Drainage-Tunnel.

The discovery at the Ella W. property, which was mentioned in last week's letter, continues to be the talk of the district. Six carloads have been shipped from it. In each the settlement is reported to be slightly less than $20 per ton. The boundary of the ore has not yet been found. It is said that as depth is gained the ore seems to be more solid and to carry better gold-values.

The recent excitement on Tenderfoot hill has caused considerable prospecting to be done lately in that area. On the Molly Kathleen property, which lies just southeast of the Ella W., a rich ore was recently reported at a depth of 730 ft. These two developments, so close to one another, have caused a small boom in that part of the district.

The flow of water from the portal of the Roosevelt drainage-tunnel is now 11,100 gal. per minute. As this is the largest flow recorded for several months, it would seem that the breast is approaching that ground in which a much larger area may be drained. The water in the Elkton shaft is reported to be receding so fast that sinking of the shaft may soon be resumed. At the present rate of progress the tunnel should be at the Elkton shaft in about five or six months.

Several sets of lessees on the Vindicator property are reported to be making large shipments of ore. It is of better grade than the average.

The new electric compressor and hoist recently installed at the Mary McKinney mine is about ready to start. This machinery will allow mining operations to be carried on at a depth of 2000 feet.

There is considerable activity at the Independence mine.

There are about 20 sets of lessees at work. Many of these are breaking a fair grade of ore. On company account development is steadily going on at several different points. On the tunnel-level, arrangements are being made for the installation of a storage-battery locomotive to haul the low-grade surface ores to the mill. A night shift on this level is busily engaged in replacing the old 12-lb. with new 20-lb. rails. The mill is running at full capacity on ore supplied partly from old dumps and partly from the mine.

MAZATLAN, SINALOA

Conditions at the San Luis, Candelaria, San Vicente, Estaca, Negociacion Minera, Tajo, Panuco, Los Arcos, Quiquitlan, Potrero, Bacis, and Tominil Companies' Mines.—Mazatlan.—Currency.—Bandits.—Food Supply.

In the San Dimas district, Durango, several companies have been breaking and cyaniding ore and developing right through the revolution, although all have been raided many times and held up for big 'loans' by bands belonging to the different factions. The superintendents and foreiguers have stuck to

MAP OF MEXICO.

their posts and deserve great credit for the way they have kept things going in spite of almost insurmountable difficulties in securing materials and supplies, and the constant molestation from revolutionists.

The San Luis Mining Co. at Tayoltita, treats about 100 tons of rich ore daily. Their Socavon mine is the richest in this part of the country. They have high-grade ore developed for several years.

The Candelaria Land, Mine & Power Co., at San Dimas, is working the old Candelaria mine, treating about 100 tons of mine and dump ore daily. The grade is much lower than in former years.

The San Vicente Mining Co., near San Dimas, but in Sinaloa, is mining and treating about 75 tons of medium-grade ore daily.

The Estaca Mining Co., also at San Dimas, a new company formed last year, is putting in a 10-stamp mill and cyanide plant and hydro-electric power-plant, all of which ought to be working by the end of the year.

The Negociación Minera de Guadalupe de los Reyes, owned by Spaniards, was raided in October 1913 by Maderistas under Mariano Arrieta-an *arriero*. They stole and destroyed about 75,000 pesos worth of merchandise, supplies, and bullion. The superintendent and staff (Spaniards and Mexicans) had to hide and flee to the coast. Work was suspended until May 1914. The mine is working again and the 20-stamp mill is operating at half-capacity. They are having almost constant trouble with bands of "istas" holding them up for money or supplies, and stealing their mules and horses.

The Tajo mine at Rosario is working, but not at full capacity. Work was suspended for several months in 1914.

The Panuco mine, owned by Spaniards, was confiscated about a year ago by the Carranzistas and is being worked for the good of the cause, or rather, for the benefit of a few of the chiefs. They are ruuning the mill to pieces and ruining the mine. One of the superintendents, a young Mexican, was killed a few month ago. Evidently he had been putting too much away for his own account. Another superintendent decamped with a tidy bit of bullion. I hear even their present superintendent is under suspicion.

The Butters Copala mines are in charge of a caretaker, no work has been done for a long time. Olaff Zetterlund, the superintendent of the Los Arcos company, near Copala, commenced development, but he had to leave owing to trouble from raiders. Charles Thomas sold his Palos Verdes mine near Sta. Lucia. The new owners have not been able to commence work yet owing to the unsettled state of the district. Some Los Angeles people are developing the old Quiquitlan mine, north-west of Tepic; they sent in a 5-stamp battery and a prospector's outfit last December. Some rich gold stringers are being worked by *gambucinos* on their extension of the Tigre claims. There must have been about 2000 people in there at one time last year, gophering the stringers.

E. H. Hoag is developing the Chirimoya mine in the district of Topia, in western Durango. He has a fine shoot of shipping ore.

S. K. Bradford is developing the Campanillas mine, in the Cosalá district. He has been working right along for two years, and has commenced to ship a little high-grade.

Both the Potrero Mining Co. and the Palmito Leasing Co., in the district of Mocorito, Sinaloa, have been treating ore throughout the revolution, with the exception of a few months in 1913. They had great difficulty in getting supplies and machinery to their mines.

The San José de Gracia mine, owned by Mexicans, was confiscated by the Carranzistas and is being worked by them. There is not a mine, owned by Mexicans being worked in the district. Don Herculano de la Rocha, Colonel, is on the warpath with the Carranzistas. He is owner of the rich Copalquin mines. Evidently he sided in with them to prevent the mines and other property being confiscated.

The Bacis Mining Co. was raided in May 1913. The manager and staff had to flee at night, leaving the mill running. Since then no work was done until quite recently, when they commenced to make repairs.

The Tominil (Mexican) Mining Co.'s plant and mine have been shut-down since August 1912, when there was a lot of trouble with strikers aided by Maderista soldiers. E. L. Shera has been doing a little prospecting, off and on, in the mine during past two years, but orders have been received from the directors to suspend all work until conditions improve.

Some good little mines, in the Cosalá district, owned by *casiques* were confiscated by the Carranzistas and were worked to supply fuuds for the Government, or better, the Governor. The man in charge "picked the eyes out," turned in about 25% of the bullion to the Government, and made away with the balance. He is now a Villista chief and threatens to confiscate all the claims and mines on which taxes have not been paid to the Villista government.

The Mazatlan water-works, owned by English and Spaniards, was confiscated last month and is now being operated by the Ayuntamiento for the benefit of the poor. They also threaten to confiscate the electric-light plant, which is owned by an American. Many houses, factories, and businesses, owned by

Mexicans (*casiques*) have been confiscated. One of the best residences is occupied by a Brigadier-General, formerly a charcoal peddler. In February they seized a gasoline yawl and cargo worth $7000. The boat was owned in Seattle and was flying the U. S. flag; cargo was owned by an Englishman. Owing to the efforts of the British Vice-Consul the boat was returned, but the cargo was confiscated and sold, the proceeds being distributed among a few of the leaders.

Exchange is now 20 pesos = 1 dollar. There are all sorts and conditions of filthy paper money in circulation, bills patched up with bits of newspaper, rags, wrapping paper, stuck together with wax and sewn. Those that will pass in one district are no good in another and so on.

All imported goods are extremely scarce and dear; it is almost impossible to buy them in Mazatlan or other towns. Even the ordinary Mexican food-stuffs and dry goods have gone up in price in many cases 1000% and are now almost out of reach of the poor. In many parts the people will suffer great want and actual starvation, between now and the maize harvest in November.

The bands of revolutionaries, infesting the country, are like locusts. They occupy a village, kill a few beeves, eat all the corn and beans, then move off to another village when there is no more grub in sight, and do the same there, leaving the people to suffer and starve. If the U. S. Red Cross Society is going to send food to the starving Mexicans, it ought to be very careful about the distribution or all will go to feed the lazy scoundrels who carry the guns, or enrich some of the leaders.

PORCUPINE, ONTARIO

Hollinger, Dome, Hollinger Reserve, Dome Lake, Vipond, Porcupine Crown, and Shumacher.—Kirkland Lake.

The regular gold yield of the district, active share market, and prospect of new properties being opened, combine to make a feeling of confidence in this district.

Profits at the Hollinger mine for the period ended June 17 were $125,920 against $139,187 in the previous period.

At the Dome the rich orebody cut by diamond-drilling is now being opened by drifts.

The Dominion Reduction Co. of Cobalt has taken an option on the Hollinger Reserve. Work is now under way to clean out the shaft and make the mine accessible for sampling. Considerable development was done on the property prior to closing down. A. G. Kirby, of Cobalt, represents the Dominion Reduction Co., and H. Poirer is consulting engineer.

The Dome Lake Mining Co. has asked for tenders for sinking its two shafts 100 ft. farther each. The company wishes to reach the 600-ft. level, as at this depth the ore which has been opened in the Big Dome and other properties in the vicinity seems to increase in value.

A steady production is being maintained at the Vipond. Both units of the mill worked most of the time in July. In cutting a station at 400 ft., prior to sinking to 500 ft., very rich ore was opened.

In the Kirkland Lake area important gold discoveries are reported from two miles north of Swastika, on the property of Harry Oakes. It is reported that several properties will start operations in this district as soon as they are able to secure electric power. A United States electric power company is investigating the field.

At the Porcupine Crown mine several thousand tons of old mill tailing is being re-treated. This material is from milling operations before the cyanide plant was erected. It assays about $2.50 per ton. The tailing is hand shoveled into a 1000-lb. self-dumping car, hauled up an incline-track to a storage-bin, and after mixing with cyanide solution is pumped to the tube-mill classifier, and then enters the mill-circuit with the mine ore.

Rumors are current of the discovery of rich silver ore about 50 miles north of the trans-continental railroad and 450 miles west of Cochrane. Prospecting parties are leaving here for the new district.

At the Shumacher mine, work is progressing favorably on the new cyanide plant. Continuous decantation will be used. The equipment will consist of a Hardinge ball-mill, tube-mill, Dorr classifier, thickeners, and agitators, and zinc-dust precipitation. The mill is expected to treat 150 tons per day.

MORAN, TEXAS

Wells, Production, Quality of Oil, Drilling Cost, Formation and Prospects of New Fields.

A recent investigation of some new oilfields in this state resulted briefly in the following conclusions:

In the Moran field, southeastern corner of Shackelford county, north-central Texas, the depth to oil is approximately 2000 ft.; thickness of sand 15 ft. (average) to 40 ft. maximum; largest initial production of individual well is 350 to 400 bbl.; and average production 5 to 25 bbl. per day each. The product is a paraffin base green oil of 36 to 40°B.

Eleven wells were yielding oil on June 7, totaling 400 bbl. per day. The sand is not highly saturated, consequently many of the wells make considerable water. The cost of drilling is high, due to considerable under-reaming necessary. Wells cost approximately $10 per foot to complete.

The field is spotted, dry holes being almost surrounded by producing wells. The structure is a low anticline or terrace on the general west-northwest dipping monocline. The general dip of the rocks is 40 ft. to the mile westward.

In the Strawn oilfield, southwest corner of Palo Pinto county, north-central Texas, the depth to oil-sand is 800 to 1000 ft.; thickness of sand 15 ft. (average) to 38 ft. maximum; largest initial production of individual well is about 100 bbl.; average daily production 20 to 25 bbl. each. The product is a paraffin base green oil 34 to 37°B. Twenty-six wells on June 5 gave a total of 560 bbl. per day. Oil sells at 35c. per bbl. at the well. The sand is not highly saturated. It usually contains oil at the top and water in the bottom, consequently most wells are being drilled too deep to make considerable water with oil.

Drilling conditions are good. The cost of wells in proved fields complete to 1000 ft. is not over $2000. Drilling can be contracted in the field for $1 per foot, the operator supplying fuel, water, and casing. Portable rigs are used.

The oil and gas fields in this part of Texas are small and spotted. The oil is of excellent refining grade, but the production of separate wells small, consequently the wells must be shallow, and cost little to complete if they are to 'pay out' in a reasonable time.

The oil in the Thrall field, near Taylor, is found at a depth of from 800 to 1000 ft. The initial yield of individual wells has been as high as 1000 bbl. per day. The average initial output is less than 500 bbl. per day. The cost of drilling is cheap, being shallow wells with good drilling formations. The product is a green paraffin base oil of about 40°B. of good refining grade. The unique feature of this area is the fact that the oil-sand at Taylor is really an old buried lava-flow that has been altered to what appears to be serpentine. This 'oil-sand' is probably a fragment of what was once a rather large lava-flow. This is shown by the fact that numerous dry wells drilled adjacent to the producing district have not found the sand.

That other portions of the same flow may exist in the district is probable, but there is no surface indication by which such buried fragments can be located. Consequently drilling for the same pay horizon in adjacent districts must be considered rank 'wild-catting.' Such exploitation is justified to some extent because the sand found at Thrall lies at shallow depth, is highly saturated, and the oil is of excellent quality.

THE MINING SUMMARY

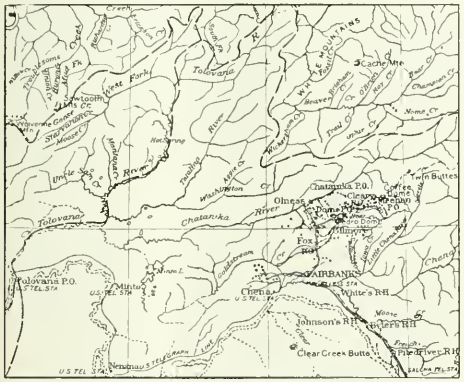
The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

Fairbanks

Early in June a shortage of water was reported from all the creeks in this district, excepting Chatanika, which is supplied by a ditch from the Chatanika river. Sluicing had been suspended. Cleary, Fairbanks, Pedro, Dome, and Vault Creek mines are very short.

In Water-Supply Paper 342 of the U. S. Geological Survey, C. E. Ellsworth and R. W. Davenport discuss the surface



SOME OF THE CREEKS IN THE FAIRBANKS DISTRICT.

water supply of the Yukon-Tanana region. The work covers 343 pages, and is complete with maps and illustrations. Briefly it discusses the general features of the area, Yukon River drainage basin, and the numerous creeks.

A tube-mill is being constructed to grind tailing from the Rhoads-Hall mine. J. H. Patterson expects to make a profit in treating the dump.

ARIZONA

Metal production of this state in 1914 was as follows, according to final figures of the U. S. Geological Survey:

Cochise County

On the north vein, at No. 7 level in the Commonwealth mine at Pearce, a good shoot was cut last week. The average assay last week was $37 per ton, mainly silver. At 150 ft. in the Commonwealth Extension shaft, 30 ft. from the south side-line of the Commonwealth, 5 ft. of $25 ore is being driven on. This is encouraging for the Commonwealth.

Gila County

(Special Correspondence.)—Four furnaces have been in blast each day at the Old Dominion smelter during July. The copper output was about 50 tons per day. The old converter is still working, now over two years. The mill has averaged over 600 tons of ore per day. Pneumatic flotation is being tried. A large ore-pocket on No. 16 level was completed. It relieves the congestion on No. 15.

Interesting work is being done by McClure and Miner at their lease at the base of the Sleeping Beauty range. They are opening a conglomerate (fine-grained monzonite) well impregnated with copper. The face averages 5%, but assays have returned 8%. The deposit can be mined by open-cut. A large tonnage is available. A railroad spur has been constructed within two miles of the mine. From there the ore will go three miles to the International smelter at Miami. Fifteen men are employed, this number to be soon increased.

Miami, July 24.

Maricopa County

In *The Wickenburg Miner* of July 8 are discussed the mining areas and opportunities contiguous to Wickenburg. Until recent years mining has been confined close to the Hassayampa river, as water shortage elsewhere has retarded development. Water, found by churn-drilling has extended the field. Gold production is growing steadily, and new plants are being constructed. Copper properties are promising. Among the mines briefly described are the Grijalva, with 24,000 tons of gold ore ready for the new mill; Monte Cristo, opened to 950 ft.; Golden Eagle, a promising mine; Copper Creek district, Bagdad being the centre; Vulture, a well-known gold producer; Unida, gold-copper ore; Arizona Copper Bell mine at Constellation, Yavapai county, copper-gold; Hite gold mine in the Blue Tank district; Yavapai county; Black Rock, near the Monte Cristo, gold-silver-copper, equipped with mill, to be re-opened in October; Red Picacho Mountain gold district with some interesting mines; Hub gold mine, 12 miles from Wickenburg; the

*Includes placer production.

Constellation district with various minerals occurring in commercial quantities; Hillside mine on Boulder creek; Wonderful gold-silver-copper mine; and the property of the Monarch Mining & Smelting Co., 10 miles east of Wickenburg. Large deposits of manganese lie 30 miles west of the town. Placer mining has always attracted attention in the region. The Rich Hill gravel deposits are seven miles east of Congress Junction, Weaver district, southern Yavapai county. The district has had an interesting history. Over $2,000,000 has been recovered as course gold. Seven large quartz veins have also been developed. The place is quiet at present. All around Wickenburg are gravel areas. Southeast are the San Domingo placers of considerable extent. The Hassayampa river can supply water all the year for sluicing. Dredging has not received much attention.

MOHAVE COUNTY

The Oatman district is described on page 172 of the PRESS of this issue.

The Brattling claims, in the Silver Creek part of the Oatman district, have been acquired by the Jerome-Oatman Mining Co., composed of United Verde and other Jerome, Yavapai county, people. There is $50,000 available for development.

The Nellie Mining Co., a new concern, has taken over the Nellie claims at the south end of the district. Little work has been done by the former owner, the Pioneer Consolidated; but they are considered valuable. A 500-ft. shaft is to be sunk, and machinery installed.

West of the Nellie, F. A. Murdock has secured an interest in the E. Schotmiller property. A hoist, compressor, drills, and other plant is to be ordered.

Globe people have bought the Gold of Ophir claims adjoining the United Western mine. A deep shaft will be sunk, starting in August.

At the Chamber of Mines and Oil, Los Angeles, a good collection of Oatman ores is on view. The whole county is to be represented soon.

It is reported that Hayden, Stone & Co., of New York, are arranging to purchase shares in the United Eastern company. The mine was examined for this firm by Ralph C. Nowland.

CALIFORNIA

AMADOR COUNTY

It is reported that the Argonaut company is negotiating for the purchase of the Kennedy Extension mine, with which it had considerable litigation in 1914.

BUTTE COUNTY

After being closed for several years the Phoenix mine near Hurleton is to be re-opened. W. P. Burke is owner.

CALAVERAS COUNTY

(Special Correspondence.)—A good deal of interest is being taken in the development of the Columbia Mines property at Angels Camp, between the Utica and Melones. This company is incorporated in California, John G. Ferraris being superintendent. The mine is equipped with a 5-stamp mill, 1250 lb. each, with a capacity of 40 tons per day; also one 25-hp. gasoline hoist, a giant air-compressor, and two drills. A double-compartment shaft is about 200 ft. deep. It is intended to sink 500 ft. deeper before cross-cutting. Development of this property is being watched with keen interest by operators at Angels Camp.

Angels Camp, July 24.

On July 15 a fire destroyed eight residences and the old 40-stamp mill at the Pine Log mine at Hodson. The loss is about $8000.——At the Royal mine 125 men are employed.

At Copperopolis the Calaveras Copper Co.'s mill is treating 125 tons of ore daily, and the experimental plant 25 tons. Flotation is employed in the former. New grinding machinery is to be installed. Development is highly satisfactory. At No. 4, 5, and 6 levels the ore averages between 3 and 4%. Fifteen tons of 10% ore is shipped daily.

NEVADA COUNTY

It is reported that the South Idaho and Gold Point mines, near the Eureka, Idaho, Maryland, Brunswick, and Union Hill properties, are to be re-opened. The options taken last year on the former mentioned have been exercised by E. MacBoyle, of San Francisco.

Electrification of the Empire mine is described in the *Journal of Electricity*, San Francisco, by R. A. Balzari. The new hoist is of the double-drum type, made by Wellman-Seaver-Morgan Co. Single-reduction herringbone gear is used. The drums are 6 ft. diameter, with a capacity of 8000 ft. of rope each. The capacity is 4 tons of ore from 7500 ft. at 1200 ft. per minute. The motor is a 500-hp., 3-phase, 60-cycle, 1140-volt, 435-r.p.m. machine of Westinghouse make. It is controlled by a liquid rheostat. Several safety devices are included. The mine shaft is 5500 ft. deep, on an incline of 30°. A 3½-ton Westinghouse Baldwin locomotive hauls six 3½-ton ore-cars to the mill. Six back-geared 35-hp. motors drive ten 1360-lb. stamps each.

On July 26, the suit of the North Star Mines Co. *v.* the Empire Mines and Investment Co. commenced at San Francisco. Apex-rights is the issue. One suit asks for a perpetual injunction restraining further alleged stealing, and another asks for $15,000 damages value of the ore alleged to have been removed in the last 20 months by the defendant.

Prominent railroad men have purchased the Polar Star mine at Grass Valley.

On July 27 a skip at the Empire mine left the track, throwing out 13 men, four of whom were seriously injured. The skip stopped at 1200 feet.

PLACER COUNTY

Gravel deposits near Indian Diggings, in the southern part of the county, have been leased by the Vacinda Mining Co. to the Amador Mercantile Co. and others for $75,000 for three years. A 450-ft. adit is to be driven.

SHASTA COUNTY

Chrome-ore claims of L. H. Brown, a mile from Dunsmuir, on the Shasta-Siskiyou boundary, have been sold to C. M. Oddie, of San Francisco, for about $56,000.

SIERRA COUNTY

The Croesus company, operating the Plumbago at Alleghany, has bonded the Bigelow quartz mine at Sierra City. A good deal of work has been done on it.——At the South Fork mine the new shoot continues to show good ore.——The 10-stamp mill at the Chipps mine has started crushing after an overhaul.

SONOMA COUNTY

After being closed since shortly after the earthquake in 1906, when several men were killed, the Great Eastern quicksilver mine has been re-opened, with eight men. A furnace is in operation producing metal. It is likely that the adjoining property, the Jackson, will be absorbed by the company.

COLORADO

CLEAR CREEK COUNTY

The Capital mill continues to work full time on company and lessees' ore. Several of the latter are doing well.——The Kane adit is in 1350 ft. Connection with the Capital mine will be complete next winter.——No. 1 raise in the Onondaga mine is up 265 ft. in good ore nearly all the way. This property is worked through the Capital.

GILPIN COUNTY

A number of improvements are being made at the Bates mine. The Leasing company is shipping good ore.——C. A. Frost and others have secured control of the Brock Hollow mine, opposite the Hidden Treasure mill, at Black Hawk.——Local business men have started work at the Ingalls mine, on Quartz hill. Good ore is extracted.——Results at the Lizzie, Stewart, and Wood mines are reported satisfactory.

LAKE COUNTY (LEADVILLE)

Station-cutting proceeds at the Penrose pumping shaft. The ground above the present water-level has been drained.——The Silent Friend mine, Big Evans district, is being re-opened by W. E. Bowden and S. J. Sullivan.——A mill is being built at the Gordon-Tiger, Twin Lakes district.——The Valley adit is in 1200 ft. in promising formation.——Preparations for re-opening the Fortune mine are progressing favorably.——A new hammer type crusher has been installed at the zinc-oxide plant.

OURAY COUNTY

After a month's idleness the Wanakah smelter resumed operations on July 21. A sintering-plant has been installed. ——Rich gold ore has been opened in the Governor mine.

SUMMIT COUNTY

During the quarter ended May 31 the Tonopah Placers Co. made a profit of $63,005.

IDAHO

LEMHI COUNTY

(Special Correspondence.)—Work has been resumed at the Golden Rule mine near Salmon. The ore contains lead, copper, and gold.——The Big Dyke claims, on Kirtly creek, containing a large deposit of low-grade ore, have been purchased by G. W. Stapleton of Butte.——Placer ground in this county was last week inspected by J. H. Miles, who operates dredges at Idaho City.

Leesburg, July 18.

At the Wilbert mine the mill is producing over 600 tons of high-grade lead-silver concentrate per month. Earnings are about $12,000 monthly. Seven cars of ore recently settled for $14,783.

IDAHO COUNTY

In the PRESS of July 24 it was mentioned that ore from outlying mines in this and Clearwater counties was being shipped by parcel-post. On September 1 the post-office will add 1c. per pound, or $20 per ton, to the present rates. This extra charge will probably prohibit ore being sent after that date.

SHOSHONE COUNTY (COEUR D'ALENE)

The Pine Creek district is attracting increasing interest.——At the property of T. Brown and J. Finnel, some rich antimony ore is being opened. Shipments will be started when a cross-cut reaches the vein in deeper ground.——At the Constitution the lessees have opened an ore-shoot for 1000 ft. There is from 2 to 5 ft. of up to 40% ore showing. Ore is being shipped. This property is 10 miles from a railway.——A 50-ton mill is to be erected at the Amy and Matchless in September.——Good results are reported from the Waters Copper, Northern Light, and Palisade properties.

The Stewart company has bought 229,000 shares of the Coeur d'Alene Development Co. with F. Burbidge and C. W. Beale's shares, and now controls the concern. The property consists of 114 acres. It has been well developed, producing ore worth over $1,000,000. The mill is operated by the Stewart company.

In the condemnation suit of the Interstate-Callahan *v.* the Puritan company for a right-of-way for an aerial tramway, the defendant was awarded $4500.

The lower adit at the Gertie, Burke, is in 2890 ft. The advance is at the rate of 11 ft. per day by two drills and three shifts of miners. The main vein is expected at a vertical depth of 1440 ft. on September 10. The adit will cost about $75,000.

Ore shipments are to commence from the Hypotheek. An electric-hoist and aerial tramway are to be ordered. The main shaft is down 1140 ft. Fred Bergen is superintendent.

MICHIGAN

THE COPPER COUNTRY

All the stamp-mills in the region are being crowded with ore. More are wanted.

At the Atlas Powder Co.'s plant at Senter, a record output of powder is expected in July. In normal times it produces 900,000 lb. per month; in July 1,100,000 lb. was expected. This shows the additional ore being broken in the copper country.

A pile-driver at Lake Linden two weeks ago drove into a live wire and caused a short-circuit. This put out of commission the turbo generator supplying power for the C. & H. dredge, tailing-grinding mills, classifiers, etc. The whole plant was shut down for some weeks. The daily output of ore from the C. & H. is nearly 12,000 tons. Last week the shops started making 19,000 hollow steel one-inch drills for the machines in the mine.

The White Pine mill is treating over 800 tons of ore daily. Fine copper in the sandstone is lost during concentration, and experiments are under way to devise a process to save it.

According to the *Daily Mining Gazette* of Houghton, production of the mines for the first half of 1915 was as follows:

Mine.	Pounds.	Mine.	Pounds.
Calumet & Hecla..	43,925,000	Centennial	1,251,000
Copper Range Con.	26,608,000	Tamarack	1,191,300
Quincy	11,091,000	White Pine	980,000
Osceola Con.	10,100,000	Franklin	348,000
Ahmeek	10,881,000	Victoria	899,000
Mohawk	7,535,200	Winona	663,000
Wolverine	4,134,000	Hancock	346,400
Isle Royal	4,556,000	New Arcadian	54,800
Allouez	4,188,700	La Salle	13,000
Mass Con.	2,890,800		
Superior	2,003,200	Total	133,659,400

Production of the Lake copper district the first six months of 1915 was brought to this stage in spite of unprecedented conditions. Soon after the outbreak of War there was a general curtailment. Men were laid off and wages reduced at all properties. The smaller mines closed entirely. The larger cut production, some of them to 50%. There was loss of efficiency and value of equipment. The middle of January, however, saw a general betterment of conditions, particularly in the copper market, brought about by the metals used in fighting, and the demand of war supplies of every nature in the American markets. By the first of February the companies had commenced gradually to bring their working crews back to normal, and to increase production. By March they were practically all back at the normal, and by April all were at full capacity. March, April, and May saw enormous production at all properties. In May the wage-scale was finally restored. In June the March, April, and May productions were beaten. July will see an even larger output.

MISSOURI

JASPER COUNTY

The districts' output last week was as follows: blende, 3669 tons; calamine, 364 tons; and lead, 543 tons, averaging $93.45, $41.82, and $59.63 per ton respectively. The total value was $408,285.

A 300-ton mill is being erected on a lease of the Bakerland at Duenweg. Sheet-ore occurs at 210 feet.

MONTANA

FERGUS COUNTY

(Special Correspondence.)—Work on the new mill at the Spotted Horse mine at Maiden has commenced. With its completion the gold output of the place will be considerably increased. Development is being done on a number of properties near Maiden and the outlook is favorable.

The Gold Acres Development Co. has just been incorporated. A. S. Wright is the principal stockholder. Frank Hazen, formerly connected with the Gold Reef mine at Giltedge, now cashier of the Empire Bank and Trust Co. of Lewistown, together with J. M. Hansen and Mr. Wright will constitute the

board of directors for three months. The adit in the company's property near New Year is now in 200 ft., with 1600 ft. more to go through the mountain before the orebody is reached. The adit will enable the old tramway to the New Year mill to be used. It is planned to have the mill in operation this fall.

A part of the Kendall mine and mill in the North Moccasin mountains has been leased. The lessees are taking ore out of the old open-cut and appear to be meeting with success. The cyanide plant will make its initial run in a few days. Three leaching tanks are already filled with ore.

The Kendall Gold Mining Co. itself is doing development with a force of 25 men. A drift is being driven toward the orebody recently discovered below the 600-ft. level by the Barnes-King Development Co. in its North Moccasin mine. The shoot is supposed to extend under the Kendall property. Besides this drift, a winze is being sunk by the company. The Kendall mine and mill have been closed for over two years, until work was started this summer.

Lewistown, July 19.

Missoula County

The mine, mill, and power-plant of the Iron Mountain Mining Co., three miles north of Superior, were purchased at sheriff's sale on July 17 at Missoula by the Federal Mining & Smelting Co., for $110,000, one-tenth down and the remainder to be paid on the delivery of the deeds. The Iron Mountain company has paid over $500,000 in dividends. It was opened 14 years ago, and has been worked eight years. It has a 250-ton mill, complete power-plant, and 11 miles of transmission-line. The mine will ship over the Coeur d'Alene branch of the Northern Pacific. The closing of the producer several years ago was the result of the law in Montana requiring every mine to have two openings. The mine complied with this regulation later by driving an adit more than a mile long on the 1500-ft. level.

NEVADA

Esmeralda County

(Special Correspondence.)—Never before have shipments of ore been so regular from this district. The Western Ore Purchasing Co. is working double shift and sampling six carloads daily, totaling 250 tons. Last month the sampler dispatched 5000 tons, and July will probably show a 50% increase. There is no indication of a falling off in the supply, on the contrary, there is every reason to look forward to a large gain. Last Monday the regular freight-train on the Tonopah & Goldfield railroad consisted of sixteen 50-ton cars of ore going to the smelter. This looks like big work and is an important factor in establishing the prosperity of Goldfield. The Las Vegas & Tonopah line is also carrying a considerable tonnage direct to the smelters around Salt Lake City. Regular contributors to the outgoing tonnage are Jumbo Extension, Atlanta, Red Top lessees, Florence, and the Consolidated. It is not generally known that a lease which ranks with the premier producers of pioneer days is steadily operating here with a gross production of approximately $100,000 per month. In June the Red Top lessees produced $132,000 of ore.

Goldfield, July 22.

The Phelan lease vein at 500 ft. in the Silver Pick is shown to be 16 ft. wide in the cross-cut. It is low-grade. North and south drifts are being driven on the vein. The water problem is being handled successfully.

Final figures of the Goldfield Consolidated for June are as follows: ore treated, 32,224 tons; net profit, $142,120; net cost, $5.28 per ton; development done, 2638 ft.; cost, $6.39 per ft.; and lessees produced 515 tons of ore with a gross value of $13,068, from which the company received $6543, less the cost of milling and transportation. A dividend, No. 23, of 10c. per share, was distributed last week. The second quarter of 1915 resulted as follows: ore treated, 95,358 tons; gold yield, $962,224; and profit, $456,910.

Humboldt County

The Rochester Mines Co. has purchased the Four J lease, in which 20,000 tons of good ore has been opened. This lease got its name from four men whose first initials were J. The mill is treating 100 tons of $15 ore per day with good recovery. It has produced $130,000 since starting in April.

In slightly over two years over 15,000 ft. of work has been done in the Rochester Mines property, exclusive of stoping. The output was over $800,000 down to 300 ft. Present workings

SILVER BULLION FROM THE NEW ROCHESTER MILL.

have opened ore for 3000 ft. The winze from 300 ft. in the Big Four is down 90 ft. This is 810 ft. above where the Friedman adit will cut the ore at a vertical depth. The vein in the winze is 7 ft. wide, with $19 per ton gold and 40 oz. silver.

A report of the Seven Troughs Coalition for the quarter ended June 30, 1915, states that 1120 tons of ore yielded an average of $84.40 per ton, a total of $94,513. Amalgamation recovered 91.65%, and concentration, 3.12%. Adding cash on hand there was $171,621 available. Operations cost $54,725, and No. 3 dividend, $36,076. The balance is $123,706. Development to 1400 ft. totaled 854 ft. Rich ore at 1200 ft. south continued toward the end of May, when the vein pinched with valueless material. The drift now shows 6 in. of $10 to $15 ore. Good ore should soon be opened again. At 1300 ft. south the drift is in the shoot 50 ft., it being from 15 to 48 in. wide. Two feet in the face assays $59.20 per ton. On June 30 samples from the stope returned from $113.60 to $326.40 per ton. At 1400 ft. the last sample gave $98.40 from 20 in. A good deal of new equipment has been added.

The National mining district, of which little is heard, has recently been described by Waldemar Lindgren in Bulletin 601 of the U. S. Geological Survey. From 1908 to 1912 one ore-shoot produced about $4,000,000. The mineral deposits of the Santa Rosa range, where the mines are situated, like those of many other parts of Nevada, may be divided into two principal classes, younger gold and silver-bearing veins that occur in or near the Tertiary volcanic rocks, and much older gold and silver-bearing veins that occur in sedimentary and associated granitic rocks. In this area the older deposits are but poorly represented, and have yielded only a small output; but one of the younger or Tertiary veins has locally been wonderfully rich, yielding much ore averaging $30 per pound. During the early period of activity a few thousand tons of low-grade ore, assaying about $100 per ton, was thrown on the dump of the National mine, but the ore shipped averaged about $30,000 per ton in gold having a value of $10.60 an ounce, the remainder being silver. The veins are inclosed in latite, rhyolite, basalt, basalt tuff, and trachyte. They consist of sheared rock a few feet wide traversed by quartz seams containing stibnite, pyrite, chalcopyrite, arsenopyrite, zinc-blende, and galena. Cinnabar was found in one of the veins. Most of the veins that carry much stibnite are poor in gold and silver. Native gold is found principally in the rich shoot of the Na-

tional vein the isolated position of which, in a district of quartz-stibnite veins poor in gold and silver, is remarkable. The several veins appear to belong to one and the same epoch of mineralization, the gold shoot being a local development upon one of the normal stibnite veins. The gold shoot was encountered 40 ft. below the surface. It has been followed on the dip of the vein for 800 ft., the stope length being 250 ft. The ore, which yielded $20 to $30 to the pound, occurred mostly in an irregular footwall seam from a few inches to a foot wide.

Mineral County

The Azurite copper claims in the Hawthorne and Mina districts were bought at a forced sale by H. Geile of Grand Rapids, Michigan, for $30,000. The Azurite Mining Co.'s debts were $63,000. The mines contain rich ore. Sinking is to be continued to open sulphide ore.

Nye County

Companies and lessees at Tonopah last week produced 11,137 tons of ore worth $226,426.——Bullion and concentrate from the Belmont for the first half of July totaled $142,000. Work has been resumed at several old faces at 800 ft.——At 1260 ft. in the Extension the shoot is 300 ft. long, averaging 12 ft. in width.——The report of the Tonopah Mining Co. for the quarter ended May 31 shows that the gross value of the ore milled was $491,483. The net profit was $229,399. Quick assets total $1,532,964. On account of low prices of silver the next dividend will be reduced.——The West End report for the year ended December 31, 1914, has been published, and will be discussed in another issue of the Press.

White Pine County

The Nevada Consolidated *Safety First* for June has on its cover an X-ray of a fractured index finger, usually an index of a fractured safety rule. Extraordinary accidents included one trouble from snake-bite, and another from fist-fight injuries. At the Ruth mine a cave-in killed a miner, and seriously injured another. At Copper Flat there were eight disabling accidents. Injuries at the mill and smelter were not very serious. At all works there were 21 accidents causing loss of time of 158 days.

NEW YORK

St. Lawrence County

A new zinc-mining district is being developed in the northern part of this state at Edwards, near Gouverneur. The ore, unusually rich, is blende mixed with pyrite, making separation difficult.

OREGON

Forty potash claims along Succor creek, have been purchased by the American Nitrate Co. of Oregon for $100,000. G. D. Huntley of Boise, Idaho, had a large interest in the property.

TEXAS

Culberson County

(Special Correspondence.)—There is much activity in prospecting and development of copper properties in the Van Horn district of western Texas.——In the vicinity of Allamore it is stated that several claims are being opened with satisfactory results. Martin Jarrell is making regular shipments of copper ore from his property in that area to the smelter at El Paso.——In the same district J. L. Johnson is preparing to begin shipping ore from his mine to the smelter.——The Copperplate Mining Co. has been organized by a syndicate of South Dakota men for the purpose of re-opening and developing on an extensive scale the old Copperplate mines, situated six miles from Van Horn. The company has its headquarters at Van Horn. It is stated that it will install machinery and place the property on a producing basis as quickly as possible. The ore also contains gold.——The Sutton Steel Co. of Dallas has taken over the Hazel mine, in the Van Horn district, and is preparing to unwater it. This mine has a splendid record as a producer of large quantities of low-grade copper ore. There are about 5000 tons of low-grade ore on the dump, and the company plans to install a mill to treat it.——J. H. Searles, of Chicago, and associates have acquired a large tract of land in the Terlingua cinnabar district of this county. It is stated that a number of outcrops of cinnabar are found upon the property. It has been decided to open these ore deposits, and to install a quicksilver furnace when the development work has made sufficient progress to justify the improvement.

Alpine, July 1.

Texas has produced during the first six months of 1915 approximately 260,000 oz. silver, 70,000 lb. lead, and 100,000 lb. of zinc. This indicates an increase in silver. These figures are included in the mid-year statement of the U. S. Geological Survey, and are based upon the report of C. W. Henderson.

UTAH

Juab County

The Tintic district shipped 193 cars of ore last week.——On August 5 the Eagle & Blue Bell will distribute 10c. per share, equal to $90,000.

Salt Lake County

Wages of about 7000 miners, mill, and smelter-men working in the neighborhood of Bingham and Salt Lake City will be increased on August 1. The increase is based on copper at 17c., and lead at 5.25c. per pound. Salaried employees get a 10% rise; skilled men earning $2.75 per day or over, 25c.; and unskilled men getting less than $2.50, 20c. Wages per shift will be as follows: machine-men, $3.50; machine-helpers, $3.25; steel miners, $3 to $3.25; maximum wages to apply only to skilled miners; timber-men and timber-men helpers increased 25c., with maximum for timber-men of $3.50; hand-trammers, $3; horse and mule-trammers, $3.25; horse and mule-trammers' helpers, $3; and nippers, $3.

A large ventilating fan is being installed at the Alta Tunnel & Transportation Co.'s tunnel, which is in 1320 ft. The Karns drilling machine, weighing 5200 lb., operated by two men, is extending the adit about 15 ft. per day. It is proposed to drive the adit 13,000 ft. to drain the Big Cottonwood mines.

CANADA

British Columbia

During July the Standard Silver-Lead company at Silverton shipped about 1500 tons of concentrate, worth $90,000, to the Trail smelter. Dividends are to be resumed in September, after a year's lapse.

Ontario

During the month ended June 17 the Hollinger produced 24,192 tons of ore averaging $9.23 per ton. The profit was $125,921. The monthly dividend of $120,000 left a balance of $5921. The surplus is $1,270,014.

According to the manager's report of the Dome mine crosscut 607 is finished. The vein is 65 ft. wide, averaging $21.43 per ton. Cross-cut 608 is being driven on the course of diamond-drill hole No. 53, which showed the vein to be 153 ft. wide, with ore averaging $14.48. This drill-hole has been followed with the cross-cut for 35 ft. and the ore averaged $19. The best ore is still ahead. Drift 609 going east along the contact of the porphyry dike is still in high-grade ore. An effort is being made to start the diamond-drills again to cut this rich orebody at different points. The manager expects to add greatly to the amount of high-grade ore already blocked out. This now amounts to 375,000 tons. He states that if for safety he cuts down his estimate of value of this ore to only $15 per ton, there has been added lately about $5,625,000 to the ore reserves.

The annual report of the Temiskaming company states that

development totaled 2805 ft. A Nordberg hoist with capacity for over 1600 ft. depth has been ordered. Deep exploration will be continued to that depth when the engine is erected.

KOREA

In June the Oriental Consolidated produced $136,500. Details of the May return are as follows: ore treated, 26,483 tons; yield from all plants, $154,231; the Candlestick mill started on May 15; 40 stamps at the Maibong are now dropping; extraction at the Maibong tube-mill was 85.6%, and with slag, 88 or 89%; and recovery at the Taracol cyanide plant 93.6%. There are 20 Korean 10-stamp mills working at Kuk San Dong. The tributers are working various stringers and pillars, and are paying the company a fixed mill rent. The company also buys the gold they produce.

MEXICO

Sonora

New currency worth ₱4,000,000 is to be issued on August 1 by Governor Maytorena, on the basis of ₱2 or ₱3 for $1 U. S. gold. So far he has had little success with the money. Two methods of disposition are to be tried: that the Cananea Consolidated finance the issue, the export and import duties of the company being deposited as a guarantee of the redemption of the issue at a rate of ₱2 for $1 gold. It is understood that the governor will insist on the company buying the new issue for use in paying its employees, abandoning the present system of paying in silver. Since the resumption of operations, the company has been paying in silver, which the workers can exchange at a rate of from ₱12 to ₱15 paper money for ₱1 in silver.

The other proposal is that the Maytorena government deposit the anticipated duties on the garvanzo (a grain) crop, which, according to estimate, will be approximately $1,800,000 gold. With this duty as a reserve for the paper money issue, the bills, according to the Maytorena party, could be circulated with a value of 33⅓c. gold. In this case the American mining companies in Maytorena territory would be compelled to buy the scrip from the Government for the payment of wages and all duties and taxes, Maytorena thus forcibly creating the demand for his new billets, according to the *Douglas Daily Dispatch*. Inability of the Governor to secure exportation of the garvanzo crop, on account of destroyed railroads, the blockaded port of Guaymas, or the cutting off of communication from south of Guaymas to the border, by the activity of either General Calles or the Indians, would result in failure of the plan. Already the American mining companies have been approached in order to ascertain what amount of the ₱4,000,000 they can be expected to take at an inflated value. Border banks also have been sounded, with results disappointing to the Maytorena faction. The new currency is of good appearance, made by the American Bank Note Company.

On account of a shortage of fuel the Moctezuma Copper Co.'s mine and mill were closed on July 15. When the railroad reopens, within about a month, work will be resumed.

The output of Greene-Cananea in July is estimated to be 3,000,000 lb. copper. Part of the mill is working. Two reverberatory, and four blast-furnaces, and three converters are in operation.

PHILIPPINE ISLANDS

Press Bulletin No. 43, dated June 15, describes the copper deposits in the Zanbales province. These have attracted attention as the known commercial deposits are in the Macayan district, Mountain province. The country is very rugged, and the rivers show the formations well. Most of the country is a porphyritic-andesite, considerably broken up. Quartz veins fill the crevices, and dikes cut the andesite. The copper occurs in small veins and masses which fill fissures and cavities of the fractured andesite. Metallic copper is found. Assays show traces of gold and silver. Several properties are described. Several mining men are disappointed with the deposits.

PERSONAL

Leon J. Pepperberg is at Portland, Oregon.

J. H. MacKenzie has returned from Juneau.

Donald Greene is here from Phoenix, Arizona.

J. W. Mercer is in Tuolumne county, California.

G. W. Wood, of Denver, was here during the week.

Francis Drake left London for Rhodesia on July 28.

Albert Burch has gone to Denver, on his way to Butte.

L. M. Rheem, of Helena, Montana, is visiting the Exposition.

F. W. Bradley is due here on August 4, upon his return from Honolulu.

Faris V. Bush has been elected a director of the Arizona Eastern Railway.

Guy A. R. Lewington, who now lives at Los Angeles, was in San Francisco this week.

Leroy A. Palmer has been making a reconnaissance in Mendocino and Trinity counties.

A. G. Keating has been appointed manager for the Big Jim Gold Mining Co., at Oatman, Arizona.

H. George Anderson passed through San Francisco on his way from Austin, Nevada, to Arizona.

Frank H. Pettingell, president of the Los Angeles Stock Exchange, was in San Francisco this week.

J. T. Marriner, manager for the Pahang Consolidated, has arrived in London from the Malay States.

George J. Young, professor of mining in the University of Minnesota, has concluded his visit to California.

Robert S. Lewis, of the University of Utah, has returned from a visit to the mines of Juneau and Dawson.

Philip Argall has just returned to Denver from a periodical visit of inspection to Magdalena, New Mexico.

F. W. Thompson has resigned as superintendent for the Triumph Gold Mining & Milling Co., of Lumpkin, California.

T. T. Read has resigned his position as associate editor of this paper to accept a position with the Engels Copper company, at Engels, California.

George H. Booth has resigned from the staff of the Inspiration Consolidated Copper Co. to take charge of the engineering work for the Mine La Motte Co., in Missouri.

W. E. Thorne, having been granted a temporary leave of absence by the Consolidated Gold Fields of South Africa, is now on the staff of the Lenskoie, or Lena Goldfields, in Siberia.

The following faculty has been chosen for the New Mexico School of Mines for 1915-1916: G. E. Anderson, geology; E. L. Quinn, chemistry; C. T. McKay, mathematics; and V. E. Hanson, civil engineering.

Obituary

Theodore B. Comstock, geologist and mining engineer, died at Los Angeles on July 26, at the age of 66. A native of Ohio, he graduated from Cornell University, obtaining a doctorate of science in 1886. He practised as mining engineer in Colorado and other Western States and contributed to the literature of his profession. He was a man of high attainments and character. At the time of his death he was president of the California Farm and Home Builders.

The twentieth annual meeting of the Lake Superior Mining Institute will be held on the Gogebic range on September 6, 7, 8, and 9, with headquarters at Ironwood. The first-aid demonstration will be held at Ironwood, after which excursions are planned to points of interest on the range. One day is to be spent on the Cuyuna range, also a visit to the Minnesota School of Mines and the State Fair, where the meeting will close.

THE MARKET PLACE

Weekly Summary of Metal Prices and Notes on the Markets.

Metal Prices

San Francisco, July 29.

Antimony	35 —35¾
Electrolytic copper	19½—19¾
Pig lead	6.00— 6.95
Quicksilver (per flask)	$95
Spelter	24 —24¼
Tin	39 —40½
Zinc-dust, 100-kg. zinc-lined cases	No quote

Supplies of zinc-dust are practically non-existent. Last week's price was 38c., and this week nominally 40c. per pound.

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, July 29.—The copper market is dull; lead shows no improvement; spelter is quiet with a downward tendency.

COPPER

Prices of electrolytic in New York, in cents per pound.

Silver is extremely weak, and lower prices are probable.

Exports of metal from London to the East to July 7 totaled £2,753,000, compared with £3,966,000 in this period of 1914, a decrease of about 12,500,000 oz. Writing on July 8, Samuel Montagu & Co. stated that the tone has been dull and heavy, notwithstanding that the quantity offered for sale has been sometimes quite negligible. An outstanding feature of late has been the prolonged abstention from buying in this market on the part of the Indian Bazaars. It is possible that their needs have been met partly from China, but this cannot altogether account for the noticeable falling off in demand from India. The speculation in the Bazaars, which has fizzled out recently, is not likely to be the sole reason for so lifeless a condition. It is difficult to account for adverse influence at work in the Bazaars, face to face with a monsoon (wet season) of fair promise, that they should be disinclined to take advantage of the falling rates that have lately obtained. One or two contributory causes are probable. Foremost is the restriction of credit, owing chiefly to a state of war. Another likely factor is the difficulty this year in marketing cotton and other commodities, and the consequent delay the ryot (peasant) suffers before he can realize those profits he is accustomed to invest in silver. Moreover, the difficulty of arranging shipping facilities, and the high rates which rule for transport and insurance add to the embarrassment, for they effect not only the export of the industrial products of India, but also the remittance of payment in bullion thereagainst.

On May 31 the Tonopah Mining Co had about 1,202,000 oz. and the Temiskaming company 730,000 oz. stored.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending			
June 30	95.00	July 14	95.00
July 7	95.00	" 21	95.00
		" 28	95.00

Monthly averages.

	1914.	1915.		1914.	1915.
Jan.	39.25	51.90	July	37.50	....
Feb.	39.00	60.00	Aug.	80.00	....
Mch.	39.00	78.00	Sept.	76.25	....

A curious anomaly in regard to the Australian zinc business is that in normal times zinc-sheets and shavings for cyanide plants are imported, while zinc-dust is exported. Rolling sheets is now being done locally. Recently experimenting has been done with a zinc-ribbon produced by fine streams of zinc falling on a water-cooled rotating drum, but it has not yet been determined whether this ribbon gives better results than zinc-shaving for precipitation of gold.

Eastern Metal Market

New York, July 23.

The metal market is in the doldrums, and it is difficult to prophesy from which direction the wind will first blow. There has been no real check to the manufacture of munitions of war, but the atmosphere is surcharged with talk of strikes at many of the big plants in as many big cities. Starting in what appeared to be an insignificant family quarrel among four labor unions as to whether millwrights should be classed as machinists, ironworkers, or carpenters, Bridgeport, Connecticut, was threatened with a wholesale walk-out at the great Remington plants located in that city, and employing thousands of hands, this on the heels of the company's announcement that it would give an 8-hr. day, with 10-hr. pay. A few hundred men struck at the Remington plant, and a few in other plants having sub-contracts, but at this writing the strike appears to be averted, just as mysteriously as it was declared. That the higher labor union officials did not favor the strike is known. There is still talk that there will be trouble at the big plant of the E. W. Bliss Co., Brooklyn, New York, which is working night and day on war orders, and at half a dozen cities in New England. Labor leaders regard the machinists' trade as one poorly organized, and in the present dearth of skilled mechanics they see their opportunity to strengthen their ranks, and place their organization on a firm basis. The general comment, even among working men, is that it is most unfortunate that disruptions should come at this time, after a long period of dullness, and just when metal workers can find plenty of employment at good wages. Where it will all end remains to be seen.

With dullness general in the metal markets all prices have declined, though it must be admitted that the quotations are largely nominal. Contrary to the situation in the metals, that of steel continues to advance, both in activity and prices. A large part of it consists of war business, either for export, or the domestic manufacture of war materials such as steel bars for shrapnel and high explosive shells. The pig-iron market, which depends more on conventional domestic manufacture, shows a little more life, but is still very dull. The trade expect a revival of demand in August or soon after that month. The demand for machine-tools such as are used in shell manufacture is sustained, and some builders have advanced their prices 30 per cent.

COPPER

The market has continued dull, with prices on the downward trend. Consumers have been so neglectful that the existing condition can be described as stagnant. In answer to the much asked question as to what is the matter with the market, two explanations are given as the primary causes: First a great deal of copper was taken a few weeks ago, then there is fear that the increased consumption may exceed requirement. The latter possibility has made buyers cautious. Again purely domestic consumption is not good, though it shows signs of betterment. The War consumption, of course, is going forward without abatement. There has been talk for weeks of war inquiries which are said to be hovering over the market, but they have not come to fruition. Quotations have declined steadily until July 21, less than 19c., cash, New York, was asked for electrolytic, although most of the producers were quoting 19.50 to 19.75c. cash. As a matter of fact, prices have been so entirely nominal that there has been no uniform level, either for first-hand or re-sale metal. High-grade Lake still commands 22 to 22.50c., with some brands quoted down to 19.25c. The exports July 1 to 23 totaled only 10,598 tons. Electrolytic was quoted by second-hands at 18.75c., cash, July 23.

ZINC

While prices have declined, the quotations for spelter are relatively stronger than those of most of the other metals. Business in prompt has been restricted by the fact that consumers are now fairly well supplied for their immediate requirements. Between July 15 and 20 the market declined about 1c. The strike troubles in New England, both actual and threatened were disquieting, but they nevertheless had less effect than most persons expected. Perhaps a greater cause of depression is the fact that the galvanized-sheet trade is dull, and buying from this direction is not heavy. The prices of this product are declining. Choice brass-mill grades are practically unobtainable at 30c., and a few odd carloads of Bertha and Horsehead have brought 40c. The exports are lighter. Foreign shipments July 1 to 23 total 2218 tons. Since the beginning of the War the exports of domestic spelter have been as follows:

August	3,079
September	17,005
October	9,160
November	11,381
December	16,309
January	13,660
February	13,394
March	8,264
April	7,894
May	6,817
Total	106,963

LEAD

The general tenor of the week has been unchanged. Deliveries of metal which was purchased in the rapid rise of a few weeks ago are now being made at a heavy rate, and many of the consumers who over-bought at that panicky time are seeking to unload even at a loss. Spot lead which is lying in the New Jersey freight-yards is being offered at substantial concessions, and is being quickly taken. The A. S. & R. Co. is still adhering to 5.75c. New York, and is reported to have done some business, though it cannot have amounted to much in view of the well-supplied condition of consumers. The re-sale metal has been sold down to 5.55c., New York. St. Louis, at 5.50c., has been extremely dull. The surplus metal must be absorbed before the market can recover its strength. The exports, July 1 to 23, totaled 1769 tons. London is reported to have done some buying, but it is believed that the purchases must have concerned Mexican lead, smelted in bond, inasmuch as London continues below New York parity.

TIN

In recent months consumers have been educated to buying far ahead, and as they are now well supplied, the market of the past few days has been inactive except for the occasional purchase of a small lot. At the same time prices are getting so low that it is felt that consumers should soon be stirred to buying. On July 23 spot Straits tin was quoted at 36.50c. Abroad a better sentiment is expected to develop with the settlement of the coal miners' strike in Wales. The London quotation July 23 was £163 10s. against £174 July 2 for spot Straits. An influence which is weakening the market is the heavy arrivals, which, up to July 23, totaled 3319 tons. On that day there was 5210 tons afloat. On one steamer which arrived July 19 was 545 tons, while earlier in the month 1000 tons arrived on one steamer from Singapore and Hongkong, and 500 tons on another boat, also from Singapore.

Current Prices for Oils and Candles

(Corrected monthly by Standard Oil Co., California.)

All prices are f.o.b. San Francisco except where otherwise specified, and are subject to change without notice.

Granite Mining Candles.	Per set, cents.	Granite Mining Candles.	Per set, cents.
6s-12 oz.-40s	8¾	6s-14 oz.-20s	9½
6s-12 oz.-20s	9	6s-16 oz.-40s	10

Petrolastic cement XX	12.00
Asphaltum	$5.50 to 12.50

Current Prices for Ores and Minerals

(Corrected monthly by Atkins, Kroll & Co.)

The prices are approximate, subject to fluctuation, and to variation according to quantity, quality, and delivery required. They are quoted, except as noted, f.o.b. San Francisco. Buying prices marked* subject immediate delivery.

	Min.	Max.
Antimony ore, 45 to 55%, per ton	*$65.00	$90.00
Arsenic, white, refined, per lb	0.04	0.05
Arsenic, red, refined, per lb	0.12	0.15
Asbestos, chrysotile	100.00	350.00
Asbestos, amphibole	5.00	7.50
Asphaltum, refined, per ton	11.50	20.00
Barium chloride, commercial, per ton	50.00	60.00
Barium sulphate (barytes), prepared, per ton	20.00	30.00
Bismuth ore, 15%, per ton	*250.00	upward
China clay, English, levigated, per ton	15.00	20.00
Chrome ore, according to quality, per ton	7.50	10.00
Cobalt metal, refined, f.o.b. London, per lb	1.90	....
Coke, foundry, per 2240 lb	12.00	15.00
Diamonds (according to size and quality):		
Borts, per carat	2.00	15.00
Carbons, per carat	55.00	80.00
Feldspar, per ton	5.00	25.00
Firebrick:		
Silica, per M	50.00	55.00
Snowball, per M	40.00	45.00
Flint pebbles for tube-mills, Danish, per 2240 lb.	21.00	24.00
Fluorspar, per ton	10.00	15.00
Fuller's earth, according to quality, per ton	20.00	30.00
Gilsonite, per ton	35.00	40.00
Graphite:		
Amorphous, per lb	0.01	0.02½
Crystalline, per lb	0.04	0.13
Gypsum, per ton	5.00	7.50
Infusorial earth, per ton	10.00	15.00
Iridium	55.00	....
Magnesite, crude, per ton	5.00	7.50
Magnesite, dead calcined, per ton	20.00	25.00
Manganese ore, oxide, crude, per ton	10.00	15.00
Manganese, prepared, according to quality, per ton	50.00	75.00
Mica, according to size and quality, per lb	$0.05	$1.00
Molybdenite, 95% MoS_2, per ton	1000.00	1500.00
Monazite sand (5% thoria), per ton	150.00	200.00
Nickel metal, refined, per lb	0.45	0.60
Ochre, extra strength, levigated, per 100 lb	2.00	3.00
Osmiridium, per oz	30.00	40.00
Platinum, native, crude, per oz	30.00	45.00
Silex lining for tube-mills, per 2240 lb	35.00	45.00
Sulphur, crude, per ton	25.00	30.00
Talc, prepared, according to quality, per ton	20.00	50.00
Tin ore, 60%, per ton	450.00	600.00
Tungsten ore, 65%	*450.00	540.00
Uranium ore, 10% min	25.00 per unit	
Vanadium ore, 15% V_2O_5, per ton	150.00	180.00
Wolframite (see tungsten ore).		
Zinc ore, 50% up, per ton	subject negotiation	

Current Prices for Chemicals

(Corrected monthly by Braun-Knecht-Heimann Co.)

Prices quoted are for ordinary quantities in packages as specified. For round lots lower prices may be expected, while in smaller quantities advanced prices are ordinarily charged. Prices named are f.o.b. San Francisco and subject to fluctuation. Other conditions govern Mexican and foreign business.

	Min.	Max.
Acid, sulphuric, com'l, 66°, drums, per 100 lb.	$ 0.80	$ 1.10
Acid, sulphuric, com'l, 66°, carboy, per 100 lb.	1.25	2.00

Zinc sheet, No. 9—18 by 84, drum, per 100 lb.	No quotes	

*Extra charge for packing nitric acid for shipment to conform to regulations.

Final figures of production in 1914 of the following minerals are reported by the U. S. Geological Survey:

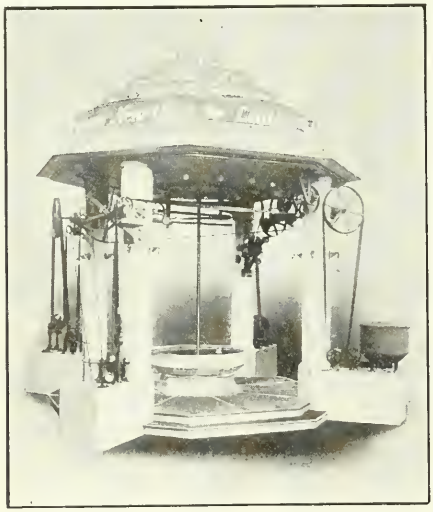
Mineral.	Tons.	Value.
Asbestos	1,247	$16,810
Barytes	51,547	153,715
Chromic-iron ore	591	8,715
Mica	4,009	606,076
Mineral paints	419,763	38,082,575
Secondary metals	....	57,039,706
Slate	....	5,706,787

New Machines and Devices

Information based on letters and catalogues from manufacturers.

Belting at the Exposition

In the Palace of Machinery at the Panama-Pacific Exposition, the Chas. A. Schieren Co., of 30-38 Ferry street, New York, has a unique operating exhibit of leather belting running on different kinds of belt drives. The pavilion is constructed of heavy steel, so as to prevent any vibration from the running machinery. The lighting scheme gives a brilliant illumination to the belt drives illustrated. A novel fountain plays in the centre of the pavilion, it easily identifies this exhibit. It



WORKING EXHIBIT OF BELTING AT THE EXPOSITION.

directs attention to the 'Duxbak' waterproof belt running *always under water* in the basin. The manufacture of Duxbak waterproof leather is claimed to have marked an epoch in the belting industry all over the world. A steam proof belt is also manufactured. There are many other belt drives arranged on the four heavy steel columns of the booth, and also on overhead transmission attached to massive structural steel work, which is above the ceiling of the pavilion. In all there are 14 belts working, running at 30 to 5500 ft. per minute. Belts for a variety of special purposes are typified by the belt drives on pedestals extending from each of the four steel columns of the booth. There are shown characteristic drives on centrifugal machines, tube-mills, wood-working machinery, pumps, etc. All the familiar belt drives are shown, and some that are new to the general public, notably the Lenix drive. This latter enables very short drives to be arranged. The firm makes belts from ½ in. to 60 in. width, as twist leather, rawhide rope, wire-screwed solid round, oak-tanned, and patent joint leather, link-belting. Water-proof leather lacing, friction packing and hydraulic cup leathers, and belt cement is also made. Interesting catalogues have been published. During construction of the Panama Canal, 18,000 ft. of Duxbak belting was used under severe requirements.

Commercial Paragraphs

The Calumet & Hecla company has just installed 23 more large-size Hardinge Mills, 16 of these for the new re-grinding plant, six for the Ahmeek company, and one for the Lake Mining, Smelting & Refining company.

Electric-hammers, according to the Western Electric Co., New York, can be operated at from 2 to 5c. per hour, depending on the size of machine used. Wherever a rapid succession of blows makes a saving, these hammers are being successfully used.

Street-lighting brackets and centre-span fixtures for Mazda lamps are discussed and illustrated in Y-679 (44 pages) of the General Electric Co., Schenectady, New York. In many instances the fixtures would be suitable for mine plants and grounds.

The Brown Hoisting Machinery Co., Cleveland, Ohio, has published a pamphlet on the Shnable patent drag-line bucket. It is a back-dumping bucket, consisting of a shell, pulling-bail, and a combination hoisting-bail and back-gate. The bucket will dig and discharge with ease fine or coarse rock, and sticky material.

Mine ventilation is important. This is shown at 'The Mine' at the Exposition, where a No. 6 Sirocco fan, manufactured by the American Blower Co., with factories at Detroit, Michigan, and Troy, New York, is blowing air into the 'workings.' The outlet pipe is 20 in. square, and the capacity is 10,000 cu. ft. of air per minute. A Westinghouse 10-hp. direct-current motor drives the fan.

A 13-page booklet from The Lunkenheimer Co., Cincinnati, Ohio, is entitled 'Grinding.' It discusses grinding as applied to valve-seats, an important detail in all works where pipes and valves are in constant use.

In a 654-page catalogue (50th anniversary in 1912) The Lunkenheimer Co., of Cincinnati, Ohio, describes and illustrates it varied products. A lot of other valuable data is given. The output of this firm is so well known that further note is unnecessary.

Antimony has risen to abnormal prices on account of the War. In our 'Mining Summary' are frequently mentioned the re-opening of antimony deposits throughout the country. The Chapman Smelting Co., San Francisco, refiners of 'C' brand star antimony, and manufacturers of commercial antimony oxides has an exhibit in the Palace of Mines and Metallurgy at the Exposition. This includes antimony sulphide ore from various districts, metal in process of refining such as the single-first process with 95% and double-second process with 99% antimony and slabs of star metal, 99.5 per cent.

The following chemicals and products are exhibited in the Palace of Mines and Metallurgy at the Exposition by the Stauffer Chemical Co., California street, San Francisco: iron pyrite, copper sulphate (crystals and liquor), lump, crude, powdered, and sublimed, sulphur, sulphuric acid, hydrochloric acid, storage-battery electrolyte, nitric acid, sulphate of iron, block, rock, and refined salt, nitrate of soda, argol, tartaric acid, magnesite ore and calcined magnesite, carbonate of magnesia, borax (crude and products), superphosphate, Paris white, carbon bi-sulphide, metallic paint, sublimed white lead, kalsomine, and other paint powders in all colors.

EDITORIAL

T. A. RICKARD - Editor

CARRANZA dollars, or pesos, are quoted at 5 cents, and Villa dollars at 1 cent each, on Wall Street. It looks as if both the Constitutionalist and the Conventionalist causes were at a discount. Indeed, Mexico has been cursed by too many 'istas. What is needed is a Mexican party.

SILVER has been down to 46.87 cents per ounce during the past week, this being the lowest on record. In January 1903 the price was 47.57. Tonopah is worried; Cobalt is depressed; particularly as the prices of the supplies and chemicals—cyanide, zinc, and aluminum—consumed in the extraction of silver have risen considerably.

REPORTS in regard to the doubling of capacity at the Tacoma copper smelter are not quite correct. It is only the refinery that is to be doubled in capacity; but at the same time a reverberatory furnace is to be added, in order to treat flue-dust and flotation concentrate, shipments of which are now coming to Tacoma from the Britannia mine.

THE National Congress of Peru, at its current session, is to consider the question of putting an end to the free exportation of minerals and mineral products. For 18 years there has been no embargo on this export trade, but now, in view of the impoverished condition of the national treasury and the depletion of the national revenues, it is possible that such a tax will be levied.

RELIABLE news from Mexico is so scarce in these days that we are particularly pleased to publish a letter from Mexico City written by a trusted correspondent. He deals chiefly with events in the southern part of the country. He explains the financial chaos and the approach of famine. We also give a description of conditions at El Oro, as quoted from a recent report of the Esperanza Mining Company.

OUTSIDE war orders, the revival of business is slow. Moreover, the diversion of energy to the manufacture of munitions has created serious disturbance in several minor industries. Adjustment to the new conditions is retarded by the lack of knowledge as to the persistence of these conditions. Nevertheless, reports from all over the country indicate that the general outlook is unquestionably good.

AMONG the legitimate efforts to arouse interest in home mining is the Mining Bureau of Helena, which has been organized to give information concerning that part of the Montana mining region which is immediately tributary to the city of Helena. The Bureau issues lists of mining properties, with details regarding development and the price of possible purchase. The mining districts within the scope of this organization include such well-known centres as Marysville, Basin, Elkhorn, and Wickes. The Bureau itself has made a start by taking an option on the Hawkeye claim, which is within the city limits, and is engaged in systematic development of the property. We commend the example.

SOUTH AFRICAN mining is affected directly by the Union's conquest of German South-West Africa because it will open a more direct route to the Transvaal from the west coast, that is, from Europe, by the way of Luderitz Bay and Warmbad. These two points are connected by rail, and a military railway has recently been laid down from Warmbad to Prieska on the Orange river, which separates the Cape Colony and the Orange Free State. Prieska is on a branch line connecting with De Aar, which is 100 miles east and on the main line between Cape Town and Johannesburg.

SMELTER capacity for zinc ores and concentrates is being increased by about 100,000 tons of metal per annum. In 1914 the total capacity of the various plants was about 450,000 tons and the actual output 364,000 tons. By the end of the current year it will be possible to treat 550,000 to 600,000 tons, and all the plants will be running at their full capacity. The most interesting of the new smelters is that being built at Donora, near Pittsburg, for the United States Steel Corporation; it will have a capacity of 40,000 tons of spelter per annum and is intended to supply the Corporation with the amount of zinc required in its own manufacture of galvanized iron. Meanwhile electrolytic precipitation threatens increasingly to supersede the method of distillation. This would revolutionize the smelting of zinc.

INTRODUCTION of new machines is often opposed by workmen, more particularly the miner, who is a confirmed conservative. Thus the Michigan copper companies had a lot of trouble when introducing the machine-drill that can be operated by one man, as against the old two-men machine. Although the use of the one-man drill helped the contractors to make more money, it aroused the enmity of the labor-unions, partly because it put a premium on efficiency, partly because it was heavy and difficult to handle, and partly because men like to work in pairs. Efforts were made, successfully, to lighten the machines and it was arranged that they should be operated in pairs. Nevertheless the introduction of the one-man drill contributed to the Michigan

strike, for it was used as a grievance by the agitators of the Western Federation. An impartial investigation by the Commercial Club showed that the opposition to the one-man drill was unreasonable. Since the strike, moreover, the machine itself has been made still lighter and more adjustable. At the Calumet & Hecla, the drill-steel has been reduced in diameter from one-inch to three-quarters, and it is likely that the other mining companies will follow suit. Improved manufacture and better material tend to lighten the weight in all machines that more immediately supplement human labor.

MEXICAN affairs are moving to another crisis, and we believe one that promises to be fairly conclusive. President Wilson has shown sagacity in asking for the co-operation of the Central and Southern republics in restoring order in the distressful country. In addition to co-opting the ambassadors of Argentina, Brazil, and Chile, he has invited the ministers of Bolivia, Uruguay, and Guatemala to a conference. Before these lines appear further information will have been published. Meanwhile it is announced that it is proposed to give the factions in Mexico a limited period wherein to end hostilities and to arrange for the orderly restoration of constitutional government. If they fail, it is likely that General Carranza may be recognized as Provisional President and an embargo placed on the exportation of munitions of war to other factions. General Carranza, it is reported, has agreed to hold an election and not to offer himself as a candidate for President. Apparently he has abated his truculence and is in a more reasonable frame of mind. This is most important, for the leader of the Constitutionalist party has neither the temper nor the personality required for the heavy task devolving on any man that is to bring harmony out of the discordant elements of Mexican misrule. By the same token all the present factional representatives will have to be eliminated, in order to minimize internal jealousies and give the new regime the chance of general support.

NICKEL is a metal for which intensified demand has been made by the War. According to information from Berlin, the price of nickel anodes in June was $55 per hundred pounds, while sheet nickel was quoted at $60 per hundred pounds. At that time the New York price was $50. The comparison suggests no scarcity in Germany. As the chief source of supply is Sudbury in Ontario, Canada, the British government has taken pains to see that none reaches Germany. From Canada it is shipped as a matte to New Jersey to be refined. In order to exercise greater control over the industry, the government of Ontario has appointed a commission to enquire into the feasibility of refining the nickel matte in Canada. This commission is headed by Mr. George T. Holloway, a British metallurgist of high repute, together with Messrs. Willet G. Miller, the Provincial Geologist, McGregor Young, an authority on international law, and Thomas W. Gibson, Deputy Minister of Mines. It is fortunate that the Imperial government insisted on the appointment of an experienced metallurgist as chairman of the commission, for it is manifest that the other members, honorable and accomplished as they are, possess no obvious qualification to decide upon the question of refining nickel matte in Canada or elsewhere. The commission looks like a sop to public sentiment, for it is extremely unlikely that its report will be applicable to any emergency created by the War.

Wild-Cats

A recent dispatch records the killing of a wild-cat in the streets of Portland. The head-line in the local newspaper suggests that the stranger had inadvertently wandered into the city from a neighboring mining district, but the details show that he had been raiding the hen-roosts, not the pockets, of respectable citizens. Time was when the word wild-cat connoted predatory schemes for selling worthless mining claims to simple people. It used to be said that Western Australia was free from rabbits because the exponents of feline finance drove back the prevailing Australian pest in its effort to encroach into the precincts of Kalgoorlie and Coolgardie. Not long ago the editor of a London periodical was threatened with a libel-suit because he described the Bullfinch mine as originally a 'wild-cat.' He explained that the term, as used in Western America, had become almost one of financial endearment and no longer conveyed any idea of villainy. The lawyer representing the Bullfinch company declined to accept the explanation, because, of course, he was not up-to-date in the use of mining terms.

To be serious, it is remarkable how the word has lost its sinister meaning. At first used to indicate schemes of deception based on worthless locations, it became employed to signify a risky venture or a forlorn hope. An enterprising and yet thoroughly respectable mine-operator would say that he was "wild-catting" in Arizona or Nevada, meaning thereby that he had bought or optioned a number of claims having only what a Cornishman calls "symptoms of indications," but usually in the vicinity of some discovery of proved value or in a new district just coming to the front. Thus the wild-cat became almost as respectable as a 'prospect,' differing from it mainly in the lack of an outcrop or other visible sign of ore. In a way, this gain of respectability was the result of the proof that orebodies valuable for the precious metals might lie under a flow of andesite or that a mass of disseminated chalcocite might be covered by a considerable thickness of worthless gossan. In short, the wild-cat became the type of venturesome mining enterprise of a quite legitimate character. Indeed, so long as the owner of a wild-cat is willing to retain possesion of his untamed property and does not use it as a lure for enticing less experienced people into flimsy share dealings, we must recognize that this phase of mining adventure plays a useful part. Without risk there would be no mining. Unless the possibilities of mineral distribution are tested by courageous explorers, we shall soon see an end to a great industry. It is the recognition of the wild-cat stage of mining as a possible

incubator of productive enterprise that causes the general public to use the term without the suggestion of either ridicule or disapproval. We should be careful not to shoot at wild-cats, even when they come near the city boundaries, until we are sure that the agile vagrant is not a respectable domestic pet made fierce by unkindly treatment. The word has come to signify a recognized feature of Western exploration; when we want to designate a mining claim that is being used for predatory purposes, let us call it a 'swindle' or a 'fraud.'

Trade With South America

Expansive ideas of creating trade with Central and South America have been chilled by a closer acquaintance with the real facts. If amiable sentiments could establish new avenues of commerce, the thing would be done already. Of good feeling on both sides there is plenty. The Spanish-speaking peoples of what is euphemistically called Latin America have suffered enormously from the War. Accustomed to do business on credits established with London or Hamburg, they find that this medium of exchange is not available to them as heretofore. They turn to their big neighbor in the North, who, like them, has found much of his customary trade shattered by shrapnel, and the fellow sufferers are now comparing notes with a view to arranging for dealings direct with each other. It sounds simple, but a new international credit system, with its elaborate scheme of acceptances and discounts, cannot be created in a day. Its predecessor was the work of years and the outcome of a confidence that had been thoroughly tested. A similar correlation of trade and finance between the United States and the southern Americas cannot be established without considerable preparation; not sowing only, but spade-work is needed. Many of our existing laws regulating banking and shipping will have to be modified for the purpose. Our banking arrangements are as yet in their elementary stage of development as regards foreign business. To talk glibly about American banks establishing branches or agencies in South America is pleasant enough at a Pan-American congress, and the National City Bank of New York, which has begun an energetic and intelligent propaganda for South American trade, has set an example by establishing three branches; but the fact remains that the 27,000 banks in this country could hardly muster 50 bank-officials properly prepared to undertake to do the work that is required in Chile or Peru, in Bolivia or Argentine. The knowledge of Spanish, as of other languages, has been largely ignored by a commercial community grown accustomed to expecting its clients and customers to speak to it in its own language. Our people are not linguists because their business is mostly with people that either speak English or take the pains to learn the official language of the United States. Moreover, most of the men likely to be chosen for a financial mission south of the equator are little habituated to foreign ways and are so set in the idea that their own ways are the best that they make poor diplomats. "Do unto others as they would do unto you, but do it first" is a simple code, but "put yourself in the other fellow's place" is, on the whole, the better motto for establishing friendly relations with strangers. To succeed in transacting real business—that is, business mutually profitable—it is necessary to forget that they are strangers.

But let us suppose that these fundamental obstacles are removed. Others remain. Individual banking houses are not likely to start a campaign in South America while the banking system of this country is still under trial. The Federal Reserve Board has begun to inspire confidence, but it is fair to say that five years more must pass before it can be said to have made good definitively. Until some such interval has elapsed not many conservative houses are going to assume the risk of a new departure abroad. Therefore the only practicable plan is to form an association of banking interests for the particular work of facilitating exchange with South America. In furnishing capital for this enterprise the various banks could participate, leaving the actual management to a board composed of financiers having special knowledge of South American conditions. The bank so constituted would then furnish the credits required for the opening of new avenues of trade. The South American is accustomed to long credits, not cash discounts; he considers that by employing personally his money during the time the bill is maturing he can make a larger profit than the discount to be received for a cash payment. Long credits, such as he has been getting at London and Hamburg, are a habit of his, and if the North American desires to trade with him, this fact must not be brushed aside as a negligible peculiarity. In any event, banking arrangements alone will not suffice. North American capital must be invested in South America and more steamships must ply between our ports and theirs, if the new commerce is to be put upon an enduring basis. And when we have prepared to meet all these requirements, we shall be haunted by the thought that as soon as the War in Europe is over our friends in the South will probably fall into their old ways of drawing bills on London or Hamburg, and preferring trade with England or Germany.

Meanwhile we may welcome such visitors as Dr. Alfonso Quinoñez, the vice-president of San Salvador, who sets all of us a good example by coming to California with the purpose of learning our language, so that he may prepare himself to aid the establishment of better commercial and political relations. San Salvador is a little country, but it is populous and rich, and it is the best governed of all the Southern republics. It lies comparatively near us and is desirous of decreasing the distance by goodwill. While New York and Boston must undertake the main task, there is no reason why San Francisco should not do her share by establishing communication, by ships and by credits, with the nearer countries on the Pacific coast. One of the means to the same useful end would be the erection of a smelter for the treatment of Bolivian tin ores. At present this tin product—usually in the form of a concentrate—is shipped to Amsterdam or Liverpool, to be used in the manu-

facture of tin-plate, some of which is then shipped across the Atlantic and thence over the continent to California for the making of the tin-cans in which our oil, fish, and fruit are exported. By smelting this tin concentrate in California and making our own tinplate, we could obviate a large number of intermediary operations. Moreover, the smelting of the ore would stimulate interest in the mines from which it was derived and would thereby promote transactions between our mining people and those of Bolivia. It would be a logical method of establishing trade. Let us hope that out of the present rapprochement between the two Americas there may arise such relations as will illustrate the realities of political economy.

Potash

Interest in potash salts has been keen in this country for several years, as consumers feel that the virtual monopoly of the output in Germany, where the trade is closely organized and production restricted, places them in an unpleasant industrial situation. This interest was accentuated last year by the outbreak of war and a further restriction of exports by the German government, followed in January last by the declaring of an embargo. Imports during the third and fourth quarters of 1914 were about one-third of normal. Imports in February of this year, as given by Mr. W. C. Phalen in the 'Mineral Resources of the United States,' show that normal amounts of carbonate of potash, caustic potash, and 'other potash salts' were received during the month. Chloride of potash imports were double the normal figures, cyanide of potash showed an enormous increase, 266,654 lb. having been received, while imports of fertilizer salts were only about one-tenth of normal. Since February 1, only one cargo of German potash salts has been received, according to the Department of Commerce. Trade conditions have been correspondingly disrupted, and it will be worth while to review briefly the various lines of progress being followed in attempting to create an independent source of supply in the United States.

The potash deposits at Searles lake, in California, are well known, and the progress made in their exploitation by the American Trona Corporation was editorially reviewed in our issue of May 23, 1914. It is only necessary to add that the process that it was proposed to use at that time proved not to be economically feasible on a working scale, and regular production has been delayed until the necessary modifications can be made. It is reported that the Corporation now hopes to be able to begin to supply the market within a few months. The search for other lake-bed deposits has been carried on both by the U. S. Geological Survey and private corporations throughout the arid regions of the United States, especially in Nevada, but without success as yet. The discovery of potassium nitrate deposits has been reported from Texas and Oregon, but they have not been sufficiently explored to indicate whether they can be worked profitably.

The alunite deposits of Utah are apparently of great promise, and a plant is under construction at Marysvale; it is reported that one of the large fertilizer companies of Chicago is the financial backer of this enterprise. The chief difficulty is that there is practically no market for fertilizer salts in the Rocky Mountain states, and the high freight-rates to the eastern and western seaboards, as compared with ocean freight-rates, places these deposits at a disadvantage.

Much has been written about the kelp groves of the Pacific coast, and much was at one time expected of them. Unfortunately kelp, when first cut, consists largely of water, and the cost of handling and removing this water is excessive. By allowing the kelp to dry in the air and then comminuting it, a product is made that is suitable for fertilizer, but there seems little hope that pure potash salts can be made from it, as the kelp tissue has absorbed the salts from sea-water and cannot easily be made to give them up again. A recent British patent proposes the use of a temperature and pressure high enough to produce the desired result. As it has been estimated that 2,300,000 tons annually of potassium chloride could be derived from kelp on the Pacific coast, experimental study will be continued, and it is quite possible that some satisfactory method will in time be devised.

Feldspar, which occurs widely distributed and in abundance, contains considerable amounts of potash. Messrs. A. S. Cushman and G. W. Coggeshall have devised a method for recovering it that consists roughly of burning the ground feldspar together with chloride of lime in a kiln, as is done with cement clinker, thus converting the potash into the chloride form. The clinker is then leached, and a product containing 75 to 85% potassium chloride is made by evaporation. There has been some delay in getting this process into operation, but the inventors are still hopeful of success. Mr. A. K. Cowles has patented a process in which ground feldspar is subjected to the action of the vapor of water and salt in a rotary furnace. This is intended for the production of sodium salts, however. The Hart process, for which an experimental plant is to be built at Easton, Pennsylvania, depends upon the fusion of feldspar with potassium or sodium sulphate. This produces a glass that can be decomposed, after crushing, with sulphuric acid, yielding pure silica and a solution of the sulphates of potash, soda, and alumina. It is obvious that the chief problem in this process is the operating cost.

Another source of foreign potash has been discovered in Spain, where large deposits have been proved to exist near Barcelona. These have not been developed beyond the exploration stage as yet, and the Spanish government is still considering the amount of control that should be exerted over the development. Strong financial interests are engaged in developing these deposits and the possibility that within a few years the German monopoly may be broken by the creation of a source of independent supply in Spain makes them of much interest to the American consumers.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Cost and Efficiency

The Editor:-

Sir—I have been much interested in the reading of an article in your journal by Mr. Heath Steele on the subject of 'Cost and Efficiency' together with your editorial review.

Your statement as to the "economic success being measured not in the cost per ton, but the profit per ton" is of course unanswerable. Mr. Steele's desire "to change the almost universal method of recording costs only in dollars and cents," while having much to recommend it from a statistical point of view, seems to me to be in conflict with your dictum in that it would attach undue importance to an immaterial part of mining operations. The amount of energy and material represented by the cost data expressed in money is comparatively of little importance except for internal check work. Apart from this I do not consider that costs are intended to furnish data for estimates. That many of the mining-cost figures published are abstruse is true, but this might be the result of managers paying more attention to the economic side of mining than to the compilation of pretty statistics, justified in some cases by the extent of the operations not being large enough to provide the necessary organization, but more often I fancy by the almost hopeless task of finding any two mines even in the same district working under exactly similar conditions.

If the working conditions are at all similar, and if sufficient analysis of the cost-sheet is made in each instance, I do not see any advantage in ascertaining, except for purely internal check, that the number of tons of ore handled per man is so much, or so little, over the statement that the same dealing in the ore costs so many cents per ton more or less. Quite the contrary. Having ascertained that some portion of my neighbor's costs were lower than mine, I should set out to ascertain the reason. In the supposititious case of two mines in the same district using identical systems of mining and milling, an ordinary detailed cost-sheet would show in what way the extra money was being expended. In any case, if one mine sorted its ore and the other did not, their systems of extracting ore could not be called identical. If it were possible to conceive two mines in a district working the same class of ore, mining and treating equal quantities, and with exactly similar mining and milling systems, any variation of cost, operation for operation, would be *prima facie* evidence of bad work on the part of one of them, and I maintain that it would be easier to consider the difference in cents per ton of ore handled than the fact that one mine used the decimal part of a pound of some material less or more than the other, or that the tons per man handled were greater in the one case than the other. One would assume, in two mines working under similar conditions, that the labor rates were the same and that their power of purchasing supplies were equal. Personally, I cannot conceive of any two mines working under exactly similar conditions, which constitutes my chief disagreement with Mr. Steele's article, and so comparison with the "other fellow" is not of much use and, for the guidance of the managements, dollars and cents per ton of ore handled are more convincing than other factors, provided that the dissection of the total is made with sufficient intelligence.

If one were to consider the "other fellow's" costs, one would naturally look at it in the terms of money first of all, and endeavor to ascertain the reason. In doing so, no one factor by itself would be of use, for example, the number of tons secured per man could only be considered in relation to the relative cost of wages. Twenty men in one district might do the work of 40 in another, and yet the cost per ton might be the same. In the former case each man would need to secure double the quantity of ore of the latter, and it would not follow that the organization and superintendence of the latter would be at fault; the management would be doing the best it could under the circumstances as they existed, as is sufficiently proved by the fact of the cost per ton being the same and the maintaining of the ratio between cost and profit.

As regards making an estimate of the cost of operating a new enterprise, the geology of the district and the nature of the country, width of lode, etc., would not be known unless some other mine was working on the same line of country. In this case one would consider the extractable value of the ore and the cost of handling to ascertain the profit to be derived. The analyzed cost-statement of the mine at work would be a safer guide than the knowledge of the amount of tons of ore handled per man under conditions probably quite different.

If an eminent mining engineer from South Africa fully primed with all the facts suggested in the article, based on his experience with colored labor, etc., were to attempt to manage an Australian mine purely on the result of his experience, applied in a hard and fast manner, one might reasonably expect disaster. Similarly, if an American used to high-grade labor were to endeavor to obtain the same results per man with in-

different colored labor, he would be worth much more than his weight in gold—if he were successful.

There is no gainsaying the fact recorded by Mr. Steele that the dollar is not a definite expression when used to denote quantities of labor and material, but it is these quantities when expressed in dollars that you have to regard, if it be true that the economic success of a mine is measured by the profit per ton and not by the cost per ton.

I fully recognize the necessity for many of the statistical data, though I am not capable of understanding the utility of recording, for example, the "drills sharpened per foot drilled by machines." The majority of the suggestions are good and the facts are, I believe, ascertainable as regards most of the large mines on this goldfield. But in recognizing the advantage of records of efficiency I cannot but think that it is putting the cart in front of the horse or confusing cause and effect to suggest that these records are of equal or greater value than the costs expressed in terms of money. Ascertain first the cost in money and then, if it is possible to compare with some other mine working under similar conditions, trace back the reason of the variation, having regard always to the various factors to be considered.

You state in your editorial comment that the unit of measure must be one applicable under varying conditions and that the dollar does not suffice in mining for purposes of comparison, but it is the dollar and not the energy and material consumed in the operation that has the effect on the profit per ton. Moreover the dollar remains constant for comparison but the energy consumed must vary with conditions. To quote further: "It is the average tonnage of ore broken per day per man that gives the relative efficiency of the labor employed." True; but it is the cost per ton of ore broken that is of more importance, particularly if you agree with what I maintain, namely, that comparisons as between mine and mine are not valuable, or rather that the essential value of comparison is of different periods on the one mine.

A. E. JACOBS.

Kalgoorlie, June 21.

Flotation at the Inspiration Mine

The Editor:

Sir—In reading an article in a recent issue of the PRESS in which the different flotation machines used at the Inspiration test-mill are described, I notice an account of one which is said to be of the Hebbard type, with agitation gear of the standard Minerals Separation pattern. As I have seen the machine at the Inspiration and read the specifications of Hebbard's U. S. patent No. 1,064,209, I wish to point out that the machine mentioned resembles Hebbard's only in not having any under-pipes connecting the spitzkasten to the mixing-boxes, chiefly because there are no spitskasten, whereas Hebbard's patent is for a machine with staggered spitzkasten, that is, each spitz is *not* exactly opposite each mixing box, as in the standard M. S. machine. In fact, his apparatus resembles T. J. Hoover's valveless apparatus, described and illustrated on pp. 144-5 of Hoover's book on flotation, and covered, I presume, by one of his patents. I understand that a machine of this Hebbard-Hoover type is, or was, used by the Zinc Corporation at Broken Hill in connection with the Horwood process and works satisfactorily on slime, but I am afraid that sand would collect in the spitzkasten. The machine at the Inspiration, on the other hand, handles sand and slime without any trouble.

W. MOTHERWELL.

San Francisco, July 29.

Concentration: Then and Now

The Editor:

Sir—I will tell you an interesting fact about concentration; we don't do as good work as was done 25 to 30 years ago. Of course, there was some dirty work then too, but on an average the mills saved from 85 to 90% of the assay-value, while now some mills on the same ore don't save 60%, about 70% being the average. I have followed the business for close onto 30 years, so I ought to know something about it. Take the two Nacozari mills; the old mill saved from 70 to 80%, the new mill from 50 to 60%, and the new mill is supposed to have all the latest improvements. When jigs were replaced by tables, the mine-owners were willing to stand a loss of from 10 to 20% to get a fool-proof machine in their mills. Anybody can tend tables and almost anyone can tend jigs, but good jig-men who know their business are scarce; at least I find it so. I would like to see one of your modern mill-men or builders handling all that table-feed on high-speed, 400 lb. per minute, and save 90% of the assay. To show you the difference in your mill-bosses, the Nacozari mill had the sieve-frame made out of wood in squares, but the cross-slats were cut in two, so that every time the plunger went down, the whole pulp came up because the sieves were far too deep. If there had been stiff sieve-frames the eccentrics would have been heated red-hot. What was the consequence? The ore worked over the jigs into the Chilean mills to be slimed up and floated out. Now take a mill in California; there the mill superintendent put in cast-iron frames and bolted the sieves on with bolts. Now, how did that work? Why the eccentrics got red-hot, so it took an extra with a hose to cool them off, and also fill the grease-cups as much as three times on an 8-hour shift. Why? Because the superintendent and foreman did not understand their business.

My contention is that all the feed that is put on tables can be better handled on jigs and make cleaner concentrate and lower tailing. But it takes first-class jig-men to do that; in fact, tailing ought to be so low that it would not pay to treat it by flotation. The speed, stroke, depth of sieve, size of mesh, size of wire, and bedding must fit the particular feed to do good work. There are mills in the Coeur d'Alene where the foreman ordered punched screens for sieves because a punched screen is cheaper; that is like saving the nickels and throwing

the dollars away. A punched screen has not enough holes at the start, and after it is in use, say, for half a day, it is blind, to stay blind.

The next time you visit a concentration plant, take a peep at the trommels and see how nice the pulp sticks together, no sizing, but wearing out the screen because the trommel is not finished right.

If you can use any of this, use it, but I don't think you will because you might lose some money in your ad. columns.

JOHN EBENSTEIN.

Salt Lake City, July 23.

Efficiency Engineering in Mines

The Editor:

Sir—The International Engineering Congress, which meets in San Francisco, September 20-25, announced a paper on the 'Organization and Staff of Mining Companies.' For business reasons, the engineer who was to write this paper has found himself unable to complete it, and the undersigned have been asked to edit a symposium on the subject. One of the many points on which we should like information is in regard to the application of the Taylor system of scientific management to mining work. It was therefore with great pleasure that we read the very interesting article by P. B. McDonald in the MINING AND SCIENTIFIC PRESS of July 24.

We have not fully investigated the references, but apparently very little has been written on the scientific management in mines and a number of the articles that have appeared are in papers devoted to coal mining and are not to be found in the public libraries near San Francisco, or, at least, we have not yet found them. And in the latest book,—'Scientific Management: a collection of the more significant articles describing the Taylor system of management: Clarence B. Thompson, Harvard University Press, 1914'—there seems to be no reference whatever to mining.

We are very desirous of having more information on this interesting subject and invite Mr. McDonald and all other engineers to send us data or articles that we can use in the symposium referred to above. Discussions of the attitude of miners toward scientific management will be valuable. Mr. McDonald writes of "the sullen opposition of a great mass of miners." Was not this due to the fact that the introduction of the scientific management was too much hurried? Taylor himself points out the absolute necessity of proceeding with great caution and slowness and states that the introduction of the system should be so arranged that a "complete mental revolution" should take place, and "that without this complete mental revolution, scientific management could not exist.

"This mental change is great and far-reaching. It means essentially a change from suspicious watchfulness and antagonism and frequently open enmity between the two sides, to that of friendship, hearty good-will, and cooperation. It means a change from the old belief that the interests of employer and employee are in many respects necessarily antagonistic, to the firm conviction that the true interests of the two are mutual."

Another point: What percentage of the saving due to scientific management was paid to the miners? In the classic case of Schmidt, his daily task was raised from 12.5 tons of pig iron handled to 47.5 tons; his wage was raised from $1.15 to $1.85. In this case the total saving made was about $2.50, of which Schmidt received $0.70, or 28%. Similar statements with regard to mining work will be most acceptable.

What is the present attitude of the management and the miners—both in the Lake Superior region and elsewhere—as regards scientific management?

We hope that some reader of this letter will take enough interest to send us the information that we ask for; it ought to be of interest to all who are connected with the mining industry.

Letters should be addressed: International Engineering Congress, Foxcroft building, San Francisco.

R. E. CRANSTON,
W. H. SHOCKLEY.

San Francisco, July 26.

[We take pleasure in publishing this letter, hoping it may elicit the information and assistance desired.—EDITOR.]

COPPER SHARES are now selling on a 20% dividend basis. This indicates that the public is convinced that the present price of the metal depends on the continuance of the War. Those who are trying to forecast the future seek to determine the effect that the decline in our copper exports, taken in combination with a rapidly increasing output, is likely to have on the price. Reduced to pounds the exports from New York were January-June 1914, 491,666,560; January-June 1915, 304,017,280. Decline 187,649,200. This drop of 38% is easily explained by the absence of Germany as a customer. But the question is: Can the copper market stand this loss in export and an increased production on a scale vastly greater than ever before witnessed? New mines are beginning to put a large product on the market and the old timers are speeding up operations to maximum capacity in order to take advantage of 20-cent copper before the tide goes out. Before the end of this year the American production of refined copper should be brought up very close to an annual basis of 1,500,000,000 pounds, a total 20% larger than the previous high point of 1,253,000,000 pounds in 1912. In addition to this home business is depressed; one of the largest brass manufacturers in this country reports that outside of the war demand the copper and brass business in this country today is not better than 60% of normal. From the speculative point of view there has been no overbooming of copper shares and in fact on several previous occasions they have sold at their present price level on a 15-cent metal market.

COPPER PRODUCTION of Peru in 1914 (bars, matte, and ores) totaled 25,070 long tons, a decrease of 2258 tons.

Buying Mining Supplies

By P. B. McDONALD

An iron-mining company in Michigan that operates half-a-dozen big mines wished to get a new type-writer. The district agent called and offered to take back the old machine at a certain price as part payment on a new one. The superintendent thought he should get $2 more for the old type-writer. There ensued much haggling. The cashier entered the discussion. After a time the manager of mines came in and took sides against the agent. They argued most of the afternoon. Finally, the agent, though still protesting that the old machine was not worth it, offered to pay the $2 out of his own pocket. The mining company would not agree to that, but the price was compromised by each side giving up a dollar. The mine officials knew that to save $1 they had used up time worth many dollars. It wasn't the $1 they were after; what they wanted was the reputation of being close buyers. They figured that a name among mining-salesmen for being hard traders was a valuable asset. Under certain conditions it is; sometimes a little saved at the spigot makes a critical difference. Such, however, is the peculiar nature of mining and the men engaged in it that it is not usually wise to run mines like a shirt-factory in a sweat-shop district. The "penny-wise, pound-foolish" spirit is apt to permeate all ranks and react in ways the management has not foreseen.

As a rule supplies bought with some sense of proportion are well worth the prices asked. There is a good deal more waste around a mine from buying things not adapted to the work than from over-charging by mine-supply houses. A superintendent devoting time to studying out what type of supplies are necessary or unnecessary will probably save more money than by haggling with salesmen. An exceptionally big order or a first order of machinery in a new district will usually succeed in securing low prices. A mining-machinery house likes to get its name-plate on installations in a new district for an example to future buyers, as mining companies frequently "follow the leader" in selecting types of machines. A certain mine-superintendent averred that mining-machinery costs $\frac{1}{3}$ to manufacture, $\frac{1}{3}$ to sell, and brings $\frac{1}{3}$ profit, until one day a salesman retorted sarcastically that the estimate was correct except he had figured the profit too low. It is not generally believed that mining-machinery houses make undue profits. Their business is erratic, they have to take chances on new types and improvements, most of them use exceptionally good material and take extraordinary pains in tempering or treating it. Some of them consistently lose money by supposing that they know all about conditions underground, and by assuming that they understand all about miners and mining men, their wants and requirements, much as it is reported American manufacturers attempt to dictate to South Americans what tools they ought to want. A large copper mining company in the Lake Superior district is surprisingly lavish in furnishing repair-parts or new tools to its employees. It figures that labor costs so much that only the best tools should be used in order to obtain a maximum efficiency. The employees, being an intelligent class of laborers, see the point and give good service. A certain mine in the South has to depend on resident labor of a shiftless sort; in self-defense it is forced to be niggardly in every respect in order to be understood by the employees. Otherwise the force of "poor white trash" and niggers would waste time, tools, and ore, in thinking the management was careless.

Only the largest mines can afford a purchasing-agent. At most properties the superintendent or manager does the buying, assisted by the bookkeeper or supply-clerk. Even when one company operates a number of mines, it often prefers to let each individual superintendent suit himself in his buying, except perhaps on contracts for comparatively staple articles, like dynamite or oils. Sometimes superintendents have to accommodate their buying to periods when the company can afford it, so they buy "by fits and starts."

It pays to have a live man to tend a warehouse, and look after giving out supplies to the miners and mechanics. Sometimes the time-keeper or mine-clerk does this. He can be of great service to the superintendent in ordering new supplies; the men make criticisms to him about tools, valves, packing, oil, etc., that they wouldn't make to the superintendent; if they did, the busy superintendent might be thinking of something else and so forget the remark immediately. A car of rails came to a mine in Minnesota, was unloaded, and the car taken away. The bill came along, deducting the weight of the car from the gross weight. The weight of the car on the bill was a whole lot less than the market weight on the side of the car, as the supply-clerk could prove by the car-number. The amount saved was appreciable.

There is a tremendous variety of articles needed at an active mine, particularly where a mine is increasing its activities. At a Minnesota underground iron-ore mine, where there are numerous pumps and engines, it is necessary to keep on hand a different kind of steam or water-packing for every piston-rod and valve, and there are dozens of them. Bushings, gaskets, gauges, valve-seats, pipe-fittings, boiler-compound, oils and greases, waste, pipe-covering, machines and machine-parts, rock-drills, pumps, explosives, illuminants, timber, lumber, tools, iron and steel, nails and spikes, lantern-globes, rails, cars, rope, wire, pipe; there's no end to what a mine needs.

FINAL FIGURES of the production of explosives in the United States in 1914 are to hand from the U. S. Bureau of Mines. They were as follows: black powder, 206,099,700 lb; high explosives other than permissible explosives, 218,453,971 lb.; and permissible explosives, 25,697,818 lb. The total weight was 450,251,489 lb., or 225,126 short tons. In 1914 the output was 250,008 tons.

GOLD OUTPUT of the St. John del Rey mine, Brazil, in the year ended February 28, 1915, was $2,200,000 from 199,234 tons of ore.

Leaching Copper Ore

By W. LAWRENCE AUSTIN

In leaching natural or artificially oxidized ore the most common practice has been to dissolve the copper by means of free acid, and then remove the metal from solution by precipitation on metallic iron. This method commends itself by its simplicity, but has the serious disadvantage that both lixiviant (acid) and precipitant (iron) enter into combinations which render them unavailable for further use in the process, unless its simplicity is destroyed. Furthermore, copper deposited from solution in the conventional appliances employed for the purpose is contaminated with other substances, and must be purified through additional metallurgical operations.

The cost of acid and iron therefore becomes of paramount importance in considering the treatment of copper ore by this process, because of the losses entailed. Where sulphuric acid has been used as a lixiviant, experience has shown that acid consumption ranges between two and nine pounds of acid per pound of copper brought into solution. This does not include attempts to leach cupriferous ore where the gangue was composed largely of lime, in which case the consumption of acid was, of course, very large—indeed, prohibitive.

Sulphuric acid (the solvent usually employed in leaching copper, but not necessarily the best in all cases) can be produced under favorable circumstances for $5, or less per ton. The price depends upon the strength of the acid. Commercial acid varies from 50° to 66° B. The latter is supposed to be straight acid (100% H_2SO_4), but often contains considerably less—as low as 93%. It requires 1¼ times as much 60° B. acid to do the same work as a like weight of 66° B. acid, and 1½ times the quantity of 53° B.

Whereas sulphuric acid can be made cheaply at industrial centres, when delivered at outlying mining camps the cost is much increased. Probably 1 to 1½ cents per pound would represent the average cost at the mine, omitting exceptional cases. As three pounds of acid per pound of copper dissolved can be assumed without serious error as representing the average acid consumption with ore reasonably free from other soluble ingredients, the cost of the acid item will, therefore, range from 3 to 4½ cents per pound of copper recovered, when the acid is wholly consumed.

Iron for precipitating purposes may possibly be purchased in large quantities for $10 or $12 per ton at Pacific Coast ports; but delivered at the mines in comparatively small quantities it will cost from 1c. to 1½c. per pound. As it requires seldom less than two pounds, and more frequently three pounds, of iron to precipitate a pound of copper from acid solutions in apparatus where the liquors are exposed to the oxidizing influences of the air, the cost of iron precipitation will vary from 2 to 4½ cents per pound of copper recovered in the form of precipitate.

The precipitate obtained by passing copper solutions over metallic iron may contain as high as 80% of copper; but usually it is mixed with other substances so that 60% copper might be considered a fair average. It often assays much less. Freight, treatment charges, etc., on this precipitate will not average less than 3c. per pound of contained copper, and may reach 4 cents.

From what has been stated in the foregoing, it is apparent that the cost of producing copper by the acid-iron method will range from 8 to 12 cents per pound of copper for the acid, iron, refining, and marketing alone, without considering mining, crushing, mechanical handling, pumping, interest on investment, amortization, and general expenses. It is evident therefore that to yield a profit at the average price of the metal some other method than the apparently simple one outlined above must be devised for leaching ore in small outlying deposits of copper.

As far as the solvent is concerned, in the majority of instances sulphuric acid will be found the most available, although in special cases resort may be made advantageously to other lixiviants—for instance, where recovery of substantial quantities of the precious metals is desirable.

But it is not necessary to consume all the acid, as is done when iron is used to remove copper from solution: it may be in large part conserved and returned to the leaching-vat, thereby reducing the acid cost very materially. This can be accomplished by employing a precipitant that liberates the acid radical from the dissolved copper without forcing it into combination with another base.

Deposition of copper from solution by means of the electric current (electrolysis) fulfills the conditions enumerated; but an electrolytic plant is expensive, and experience is necessary for its proper manipulation; besides, it has defects of its own. In starting a small leaching operation it is best to avoid burdening it with such a delicate factor as an electrolytic department, however attractive the method may appear from a theoretical standpoint.

Among chemical precipitants there is one that completely removes copper from any solution obtained in ore-leaching, no matter how little of the metal it contains. It is cheaply produced and has been repeatedly used for the purpose indicated. This reagent is hydrogen sulphide (sulphuretted hydrogen), and there is much to recommend its use as a commercial precipitant of copper from ore-lixivium.

Hydrogen sulphide acts on a copper solution as indicated in the formula: $CuSO_4 + H_2S = CuS + H_2SO_4$. In other words, when the gas (H_2S) is brought into contact with a copper sulphate solution (lixivium) at ordinary temperature and atmospheric pressure, copper sulphide (CuS) is thrown down as a black precipitate, and sulphuric acid (H_2SO_4) is liberated. The reaction is complete—all the copper is quickly removed as a solid and settles out of the liquor. After allowing the copper sulphide to separate, the clear solution containing free acid is ready to be returned to the leaching-vat to dissolve more copper.

Among the advantages of employing hydrogen sulphide as a commercial precipitant for copper are:

1. The use of weak lixiviants is permissible, and a rich lixivium is not necessary as in electrolysis. Hydrogen sulphide will precipitate copper from a solution carrying one-tenth of one per cent (0.1%) of the metal just as well as it will from a 5% solution. The advantages of this feature are manifest. In employing weak acid lixiviants (1% acid by weight) a selective action of the acid for the copper is exercised, and other elements are only slightly attacked. Consequently less acid is consumed. A 10% acid lixiviant dissolves the oxidized bases indiscriminately, thereby causing heavy acid consumption and increasing acid cost. Concrete vats and launders may be used with weak acid lixiviants.

2. Hydrogen sulphide introduces no foreign salts into the leaching liquors. When the blue, or green, color of the lixivium has disappeared the operation is complete: all the copper has been removed, and, after settling, the solution can be returned to the leaching department.

3. Hydrogen sulphide for metallurgical purposes can be made in a number of ways. The usual method is to treat iron monosulphide (FeS), or matte, with sulphuric acid; but there are cleaner, as well as cheaper, means, familiar to chemists, by which the gas may be obtained in large quantities.

The gas has poisonous qualities, and for this reason objection has been made to its use. The same fault can be found with fuel-gas, also illuminating gas. Hydrogen sulphide, like carbon monoxide, can be handled with safety when proper precautions are taken: the one need be no more dangerous than the other.

Hydrogen sulphide gas has been employed in several places for precipitating copper from mine-water. It is a matter of record that the gas was successfully applied for the purpose specified after precipitation by means of metallic iron had proved unremunerative.

4. Hydrogen sulphide is an inexpensive reagent, and the apparatus required for generating the gas is simple. As there are various methods of manufacturing hydrogen sulphide, the apparatus must necessarily conform to the material available in the locality where it is to be employed, and will therefore differ in construction and cost. The plant need be no more expensive than a chlorine gas generator in an old-time chlorination plant.

Under average conditions hydrogen sulphide gas can be generated for two cents per pound, or less, and as a pound of the gas will precipitate nearly one pound of copper as copper sulphide, the cost of depositing the metal from cupriferous solutions will be approximately 2¼c. per pound of copper. But there is this difference as compared with iron precipitation: the acid combined with the copper is conserved and in condition to treat fresh ore.

Copper sulphide when deposited from aqueous solution is a slimy black mass, which settles rapidly. Pure copper sulphide contains 66.5% copper; but that resulting from metallurgical operations, when unwashed, carries from 52 to 58%. When filter-pressed the cakes of copper sulphide are reported to retain 48% moisture.

Copper sulphide precipitate can be air-dried and shipped to a smelter, or it may be smelted to metallic copper in a small reverberatory on the ground. A method has lately been devised by means of which copper sulphide deposited in settling-tanks may be drawn off through a pipe and treated without drying or filtering. The final product may be metallic copper, if desired. In this treatment the sulphur is recovered in a form that can be used for making hydrogen sulphide gas, and the copper can be metallized for about two cents per pound. Recovery of the sulphur reduces the figure (2¼c.) mentioned above as the cost of depositing the metal as copper sulphide.

Based on the data given, the cost of material consumed, in treating ore when the hydrogen sulphide method of precipitation is employed, should be approximately as follows:

	Cost per pound of copper.
Acid consumption one pound (combined with bases other than copper)	$0.015
Hydrogen sulphide one pound (from this deduct sulphur subsequently recovered)	0.0225
Freight and treatment (same as for iron precipitate)	0.03
Total	$0.0675

These figures are comparable with the $0.12 cost given as part of the expense of the iron precipitation method.

A copper-leaching plant using the hydrogen sulphide method of precipitation is nearly as simple in construction as one using iron precipitation. A couple of additional tanks for precipitation and settling, and an inexpensive gas-generator, take the place of the iron-precipitation boxes. There are no patents in force covering the precipitation of copper by hydrogen sulphide gas: the method is an old one. Conservation of the leaching acid is the principal advantage.

When the crude precipitate is shipped to a smelter the expense of precipitation in either case will be about the same with average cost of materials. Under conditions where generation of hydrogen sulphide is inexpensive, and iron is difficult to obtain, results may be much in favor of the hydrogen sulphide method. When the copper sulphide is treated locally, the cost of hydrogen sulphide may be reduced through conservation of the sulphur, and a saving in refining charges may be effected in addition.

Safety in Mining

Public hearings to consider mine safety rules were held in San Francisco on June 11 and 12, on the initiative of the Industrial Accident Commission and the U. S. Bureau of Mines, the latter being represented by Mr. H. M. Wolffin, who had recently made a tour of the mines of this State. In the course of the discussion, upon the phrasing of these rules, the mine managers present contributed a good deal of information of practical importance. We have selected such portions of the record as seem likely to be useful to our readers.

The factor of safety in the strength of hoisting ropes provoked a long discussion. In the tentative rules the factor of 5 was adopted, but an increase to 8 was suggested. The lower margin is that adopted by rope manufacturers; the higher one would entail expensive changes and enormous inconvenience to the owners of mines. One veteran engineer said:

"Increasing the factor of safety of ropes from 5 to 8 will involve a large expense. The factor of safety of 5 has been the custom so long that hoisting-engines are designed for ropes of this strength. In many cases changing the factor of safety will mean changing the drums in order to put on larger ropes, and in the case of deep shafts it will increase the weight of the rope to such an extent that the capacity of the engine will be cut in two, making it impossible to hoist the ore necessary to keep the mills going without buying an entirely new hoisting-engine. If you will figure out the size of rope necessary for, say, a 4-ton net load, weight of skip 5000 lb. and 5000 ft. of rope; for the factor of safety of 8, you will find that the weight of the rope increases so fast that it is impossible to comply with the rule. This is taking the breaking-strain as given in the tables for plow-steel hoisting-rope."

Another manager said: "Hoisting-drums in the Lake Superior country, where they have shafts 5000 ft. deep, could not possibly operate under a factor of safety of 8. The Red Jacket shaft, which is 4900 ft. deep, handles about 17 tons dead load, that is, the weight of the rope and skip. It has $1\frac{1}{2}$-in. rope with a breaking-strain of about 100 tons. That is a fraction over the safety factor of 5. They have had no accidents in their shafts due to the breakage of ropes there since the deep shafts have been put into use. There are 4 shafts deeper than 3000 ft., 3 shafts over 4000 ft., and 2 over 5000 ft. At the Sacramento shaft of the Copper Queen mine, a net load of 13,000 lb. is hoisted on a 4400-lb. rope made of $1\frac{1}{4}$-in. crucible-cast steel. This gives about $8\frac{1}{2}$ tons dead load; a $1\frac{1}{4}$-in. rope has a breaking-strain of 47 tons, so they are operating at a fraction over the safety factor of 5."

Several experienced managers testified that they had been operating for long terms of years under the lower factor (5) without any breakage of the rope. Reference was made to Hans Behr's paper on deep winding on the Rand and he was quoted as saying that the factor of safety in force would limit operations to a vertical depth of 5500 ft., because the weight of the cable would become unmanageable. In specifying for the new electric hoist to be erected at the Plymouth mine, a factor of 7 has been given. It was suggested that the time of service of the rope should be considered; that any rope is seldom in use for more than 18 months; and that if inspected carefully and frequently a factor of safety is introduced thereby.

The provision of overhead bars for giving men on cages an easy and secure hand-hold was adopted. But the forbidding of men standing on the top of a skip, or on the bale, raised a protest. One engineer insisted that "in an inclined shaft the best place to ride is to sit on the bale and put your feet on the lip." That the placing of boards on the top of skips is a common practice and one devoid of danger, was urged by more than one manager. To this it was retorted that it was inconsistent with the effort to enforce the rule providing for enclosed

cages in shafts. Whereupon another engineer suggested that the regulation should limit the number of men rather than prevent anybody from riding on boards properly laid on top of the skip. The limitations proposed was one-half the total capacity of the skip. This would allow skip-tenders, shift-bosses, superintendents, and the like, to ride up and down without having to attach the enclosure that is used while changing shifts.

The regulation that a man must stand on the skip when giving the signal aroused objection. If the bell-rope broke, the man might fall into the shaft. If it broke before the signal was completed, the man might be hoisted onto the dump. However, he can ring three before he gets into the skip, and then he rings one. The bell-cord system is yet largely in vogue in the West, although the electric-light method is displacing it. The telephone system, which is still better, is gaining ground over both the others. On the whole, the objection to this regulation missed fire.

In regard to ladders, it was agreed that the rungs should be at intervals not to exceed 14 inches and that the permissible variation should be one inch. A space of 3 inches between the rung and the wall or timber behind the ladder was accepted as convenient, the ladders being made usually of 2 by 4-in. stringers countersunk for either the whole or a portion of a 1 by 3 or 4-inch piece.

To prevent the making of dust in drilling, a regulation was drafted for the compulsory use of a water-jet spray instead of respirators. Objection was raised. It was stated that "the miners will not use the spray that is provided." They will use the respirators to prevent themselves from inhaling the dust, but not the sprays that stop the creation of dust. The Bureau of Mines representative agreed in part, but stated that where drills with hollow steel (the water being forced through the steel) are provided, there seems to have been some success in getting the men to use them. In Government work it has been found quite as difficult to get the men to use respirators, which are uncomfortable, as to use the dust-laying devices. The extra cost of using the type of drill mentioned was asserted to be "at least seven times" that of the 'stoper' used in most of the California gold mines. The necessity for employing a bar or column with the hollow-drill type makes its use much less flexible. To this one of the managers replied thus:

"We tried to use the water-spray with the hammer-stoper, and the men threw it away. We also tried to introduce the respirator. Some used it and some did not. Our particular conditions, at Grass Valley, make the Water-Leyner type of drill the most efficient because it is better for us to mount the machine on a column than to use the hammer-stoper. We also found the Water-Leyner machine is more expensive to operate per shift. It costs us about $6.25 per shift to operate a No. 8 Leyner as against $3 per shift to operate the hammer-stoper. But as we have a flat-dipping vein, the stoping conditions make the Water-Leyner type of machine the best for our purpose. We have had no luck at all with the water-spray, and very little with the respirator."

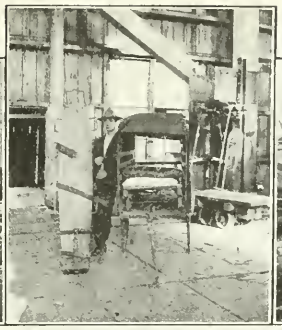
Another manager replied: "This rule more than any other threatens the future of the mining industry. It practically forbids the use of the stoping-drill, the most efficient rock-breaking machine under some conditions that has ever been built. Dust is unpleasant to work in and if the rock is highly silicious it is unquestionably injurious to health; but respirators can be made, and are made, that will absolutely prevent any dust passing into the lungs. A rule compelling the men to wear such respirators will have the effect which the Commission desires to accomplish in protecting health, without inflicting a burden on the mining industry, that in some cases will threaten its existence.

"In regard to the respirators, we have some dusty places in the mine, and the men for a number of years past have been buying and using respirators of their own accord. We never made any regulation about it or even suggested their use. They buy them and use them and are perfectly satisfied.

"Another difficulty and expense is the use of water. In many cases it is difficult to have water piped into the stopes. You have to have a second pipe-line that has to be taken out every time there is blasting, which means double operation in getting ready. Another objection to the column type of drill, either with water or not, is in the placing of it. This operation requires half an hour to an hour and one-half, depending on the character of the place, whereas the stoper can usually be set up in a few minutes. It is extremely efficient in hard ground, and has made, I believe, the fastest drilling record. Compared with the others, the labor is quite high, and it requires a better type of miner to operate efficiently than any other kind of machine. We have been testing these machines recently, and I think I do not exaggerate in stating that if this rule is passed, the use of the respirator prohibited and the use of water-spray made obligatory, it will threaten the existence of the mines on the Mother Lode."

To this the representative of the Bureau of Mines replied: "In mines where the stoper is used the ground is very hard and they have discarded all piston-drills or will discard them as fast as possible in favor of the Leyner. In stoping with this form of machine, while not always possible with the present construction of the machine to use it economically in California mines, it is possible under some conditions to use it more economically than the hammer-stoper. The Homestake Mining Co. has made extensive tests and has decided to use the Leyner drill because it is more economical. In regard to the hammer-drill also, the dust is hard on the men. I have seen surgeons of the Bureau of Mines examine men who were working in dry mines with these hammer-drills and find evidence of silicosis in over 35% of the men examined, that is, one man out of every three was affected. The respirators, while they will answer the purpose, if worn, are very uncomfortable, for I have tried to wear them myself over periods of several months and know what the discomfort is. Furthermore, if some reasonable

Unguarded Collar of Incline Shaft, Showing Inflammable Material Piled Near-by.



Stretcher Used at the Homestake Mine.

Carelessness in Not Replacing Guard-Rails at Top of Inclined Shaft.

dust regulation is not made at the present time, I think it likely that a more drastic regulation will be introduced at the next Legislature, and we cannot at that time stand between the operators and the men."

Many managers testified that the men would not use the spray, while some of them would use the respirators. Another manager made this appeal to the Commission:

"We have tried and made some elaborate tests on hollow-steel drills. On account of the hard rock we found the cost of stoping absolutely prohibitive. If it is necessary for us to put in the hollow-steel drills, it will mean closing-down as soon as the law goes into effect. While it will not work much of a hardship on the company, it will on the community."

In the end the rule was modified allowing of "other means equally efficient to prevent the inhalation of dust." The respirator won.

Objection was taken to the use of the canvas stretcher, especially where an injured man is to be carried down a raise or manway of small size. Instead, the managers approved a wooden stretcher, provided with straps to go around the body, a foot-rest, and an iron hook at the top whereby the stretcher with the injured man firmly attached can be suspended and easily lowered through any vertical opening. The main part is a board about 12 to 14 inches wide. Any carpenter can make it. The Homestake mine supplied the model.

It was agreed that 'a 'leaser' is not the same as a 'lessee,' that the ordinary legal significance of the latter does not apply to the man who has limited rights to work in a part of a mine under strict conditions. A 'leaser' is an employee; a 'lessee,' a tenant not subject to orders but operating on his own account.

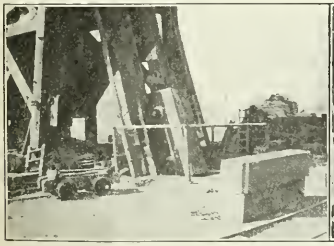
The use of grease or oil to water-proof joints between cap and fuse was condemned, as causing misfires and otherwise dangerous. Instead, roofing paint was recommended for this purpose. Also ordinary white laundry soap.

It was the opinion of many that it was safer to ride on a loaded skip, being more likely to stay on the track, than on an empty skip, in certain mines where the factor of safety of the rope is ample, and the track is somewhat rough, or where the construction of the skip is such as to admit of the possibility of its being overturned when empty. Ordinarily, of course, it is not considered safe to ride on a loaded skip because of the danger of falling off, and the probability that if the rope breaks it will do so when under the strain of the load.

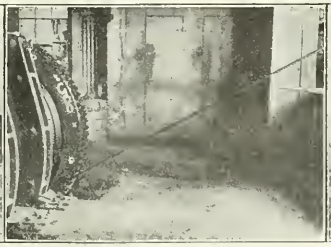
All injuries or accidents, it was decided, should be reported before going off shift, because many slight abrasions and hurts become serious, especially in coppery water, if not given medical attention.

The shift-boss received proper recognition, it being agreed that reports concerning conditions underground, such as dangerous places and the like, should be reported to him. In many rules the shift-boss was coupled with the foreman.

It was suggested that no man should 'spit' more than 15 fuses at one time without another man to assist him. On the other hand, an opinion was expressed that there are many miners who get excited when a fuse does not ignite quickly, and when they have to cut it again to



Shaft-Guards in Place at Collar of Incline-Shaft.



Unguarded Hoist-Drum and Rope.

Inflammable Mill-Building Close to Shaft that is an Intake Air-way.

make it 'take' they lose their heads. It depends upon the position of the working-face, that is, the facility for an easy exit to safety. In a drift a miner can spit 15 or 20 fuses comfortably, but in the bottom of a winze, where escape means the climbing of a chain-ladder, and so forth, 5 fuses would be enough.

Testimony was given that in firing holes surer results were obtained with fuse than with electrical firing. Also that the use of the lighting circuit was more satisfactory than a battery.

As to returning to a place where a charge has been exploded, it was held that in a well-ventilated mine an interval of 15 minutes would suffice to ensure the escape of fume and also the danger of missed holes; but it was stated that the Bureau of Mines had a record of shots that went off three hours after the fuse was 'spit,' and even longer. Forty minutes was suggested as a compromise.

The use of shower-baths in change-houses has decreased many kinds of infection, where the men have been persuaded to use them. It was argued, however, that a change-house it not a 'place of employment' and that therefore the use of either the change-house or its shower-bath could not be made compulsory on the men nor the providing of it compulsory on the mine-owner. It is a place to which the miner goes *after* he has done his work. On the other hand, the change-house and its conveniences minister to the 'welfare' of the worker and to the ability of the owner to restrict the stealing of rich ore. The 'place of employment' is the employer's premises, where the workman is under the authority of the employer. Therefore this comes under the jurisdiction of the Industrial Commission or similar authority.

In regard to oil underground, it was agreed that the quantity did not matter so much as the place where it was kept. As one manager said: "If the oil is kept in a place distant from timbers and is not likely therefore to leak and soak into the timbers and catch fire, the quantity cuts no figure. The oil itself is not readily inflammable, but it is the timber soaked with oil that is inflammable."

The question arose as to whether dynamite should be carried on a car next to an electric locomotive underground. It was suggested that the dangerous load should be placed on a rear car, that an empty car should intervene, or that a long coupling should be used, so as to keep the dynamite-car away from the trolley and prevent a vagrant spark from dropping on the dynamite. A regulation might be framed providing that the dynamite-car should be separated from the locomotive by a fixed distance. The question was left undecided.

Red wrappers are used on dynamite cartridges at many mines. It is claimed that the red wrapper is more effective in making cartridges visible and in aiding the detection of them in broken ore than the brown. The companies supplying explosives do not charge extra for the red wrapper now, but they used to charge $\frac{1}{2}$ cent apiece. Owing to the War and the scarcity of aniline dyes, the supply of these red wrappers has run short, but this is to be corrected by the end of the current year. It was stated that the red wrapper was adopted during the driving of the Simplon tunnel. It was found to lessen accidents. Then it was introduced at the Mammoth mine, in Shasta county. As the manager of that mine said: "It is much more easily distinguished in broken ground, and in the faces where the powder remains in the drill-holes you can see the red wrapper 20 ft. away, but with the other wrappers it was not unusual for men working in the face not to know powder was there."

The use of water on burning 'powder' tends to increase the danger, according to the chemists of the Bureau of Mines. Incidentally, it is noteworthy that 'powder' is used as a synonym for dynamite, thus perpetuating a term inherited from an earlier period when sporting powder was the usual explosive.* Among fire-extinguishers, those using pyrene were mentioned as less dangerous than those using soda and acid, the latter being on a par with water. Sand was said to be used in Arizona to extinguish dynamite fires, but no faith was expressed in this method.

Signs to indicate where blasting is in progress outside regular hours are desirable. It was suggested that "the time of all blasting and firing shall be fixed by the superintendent, and notices giving the times of firing shall be posted in prominent places at the entrance of the workings, and at the various shaft-stations. No firing shall be done at other than the stated time unless all entrances to the working place are guarded by men or by placing in the 'traveling ways' signs of warning or red alarm lights. Such protection shall be given at bottom of raises and at the top of winzes, and also in the working-levels."

The relative merits of strap-iron and T rails were debated. Opinion was evenly divided. For incline-shafts the strap-iron was especially suitable. It was recommended in shafts where the live load is less than 4000 pounds and the rope-speed not over 300 ft. per minute, provided that the strap-iron is bolted through the stringers. It is easier to make an inspection of a shaft with T rails than of one equipped with strap-iron. If the end of a strap is loose, it is discovered only when the skip passes and is jarred. A loose bolt is not readily detected by looking under the track. One engineer asserted that heavy iron, such as $\frac{5}{8}$-inch, properly bolted, was as safe as any T rail. Frederick Hellmann, formerly manager of the East Rand Proprietary, was quoted as having stated that the best installation for a rope-hoist in an incline shaft consisted of longitudinal stringers equipped with heavy strap-iron. The Tennessee Copper Co. was said to hoist 3000 ft. on a 75° incline, using strap-iron made to conform to their design. It was complained that to forbid the use of strap-iron would be a hardship to small operators, especially those at a distance from the railroad or from wagon-roads.

Any visitor to the hoist-room must remain in sight of the engineer while the hoist is in motion. This refers to officials who have some business there. It makes the

*See Mr. E. G. Spilsbury's reminiscences in our issue of July 10, page 42.—EDITOR.

engineer nervous for anybody to come into the room and get behind where he cannot be seen. It was suggested that all visitors be excluded.

Marked difference of opinion was elicited in regard to the use of wood and pipe rails as against chains, for guarding the approach to a shaft. The weight of one and the sagging of the other were given as defects. It was argued that a chain was easy to detach and throw aside when necessary, while a wooden bar is heavy, especially when wet. When employing a pipe-railing it is usual to have a centre-post, which gets in the way when timbers are being loaded. If the centre-post is removable, it may fall into the shaft. On the other hand, the chain must be loose in order to allow play for hooking it; then it sags and may cause a man to trip. If tight, it is difficult to hook and the men leave it unhooked. The guarding of shafts, it was agreed, was so important that the matter was referred back to the committee.

PRODUCTION of crude borate materials in the United States in 1914 was 62,400 short tons, valued at $1,464,400, compared with 58,051 tons in 1913, valued at $1,491,530. This is an increase in quantity of 7½%, according to Charles G. Yale and Hoyt S. Gale, of the U. S. Geological Survey. All the crude borate material now used in this country is the mineral colemanite. The product during 1914 was obtained from three mines, all in southern and southeastern California. The larger part came, as usual, from the Lila C. mine of the Pacific Coast Borax Co., in the mountains of the Death Valley region of Inyo county. During the year this company completed a calcining plant at Death Valley Junction to roast the lower-grade ores before shipping them to New Jersey to be refined. It also completed a narrow-gauge railroad from the Tonopah & Tidewater line at Death Valley Junction to the Biddy McCarthy and Monte Blanco mines of the company in the Furnace Creek region, which have not yet been operated. The Sterling Borax Co., near the border of Los Angeles county, was second in production. Two grades of ore are mined. They are roasted to remove impurities. On calcination the colemanite content of the ore is dehydrated and becomes a fine powder. The Stauffer Chemical Co., of San Francisco, which was once interested in the borax mines at Lang, has obtained a controlling interest in the holdings of the Russell Borate Co. in the Ventura district. This company hauls the ore 35 miles to rail and ships it to San Francisco for refining. The season is limited to about seven months in the year on account of heavy roads in winter. A 40-ft. deposit of colemanite is reported to have been discovered at a depth of 370 ft. by ranchmen drilling for water about four miles from Rich station, in the Kramer district, San Bernardino county.

SALT PRODUCTION of the United States in 1914 totaled 34,804,683 bbl. of 280 lb. each, equal to 4,872,656 short tons. This was valued at $10,271,358. The output was an increase of 405,385 bbl. Imports were 934,319, and exports 587,818 bbl., a decline and increase respectively.

Leaching Slime Tailing

By LAWRENCE ADDICKS

*In devising a scheme of metallurgical treatment for the ore of the Burro Mountain mine, it was at first planned to subject the ore, containing 2.35% copper, to preliminary concentration, yielding a tailing of which one-half was sand containing 0.3% copper, and one-half slime containing 1% copper. Before the experimental work was completed it was found that flotation would yield a tailing too low in copper to justify re-treatment, but the research was completed in order to have the data on record.

The first step was to separate the solid material from the thin tailing pulp. It was first thickened in a standard Dorr unit to a consistence of 1 to 1. This thickened pulp was then run into shallow basins where it was allowed to settle and dry by evaporation; the tests indicated that it could be thus dried down to 10% moisture within a reasonable time. Material containing 25% moisture was also dried in a 7 by 31-ft. rotary kiln, using oil for fuel. The results with this indicated that ½ gal. of oil must be burned for each unit of moisture in the material to be dried. It was necessary to provide means for crushing any lumps formed, otherwise they would be burned hard in the subsequent roasting.

The roasting was done in a standard 6-hearth 18-ft. MacDougall furnace. Roasting at the rate of 100 tons per day, 3½ gal. of fuel oil was burned per ton. The proper roasting temperature lay between 900 and 1100° F. The slime before roasting averaged 0.84% copper, and the calcines averaged 0.74% copper. It is thought that this was due to the formation of anhydrous copper sulphate, which was carried away with the flue-dust. The hot calcine was discharged into a sloping trough containing a 3 to 4% solution of sulphuric acid. It was found that 90% of the copper extracted by leaching was taken into solution during passage through the trough. The removal of the dissolved copper from the slime was a difficult problem. Continuous counter-current decantation with Dorr thickeners was finally adopted. Some changes in design were necessary, but the equipment, on the whole, proved practicable. The chief difficulty was with the air-lifts, and a diaphragm pump was substituted, with complete success.

The liquors during the run accumulated sulphates corresponding to 10 lb. copper, 4.3 lb. iron, and 16.2 lb. alumina, the consumption of sulphuric acid being 49 lb., per ton of slime leached. The acid equivalent of the metallic oxides is 70.5 lb., showing that a good deal of sulphate is present in the calcine. The run was not long enough to determine whether the impurities were dissolved in increased amounts as the liquors became more concentrated. The experiments indicated that an extraction of over 70% of the copper present in the slime could be maintained in practice.

*Abstract of a paper to be presented at the September (San Francisco) meeting of the American Institute of Mining Engineers.

Joplin and the Spelter Boom

By OTTO RUHL

The whole zinc industry of the United States has been growing more prosperous for the last 10 months, arousing the interest of everyone connected with the business or in the least affected by the rapid changes in prices. It is not clear just where the final adjustments will be made, hence differences in opinion as to the future are not surprising. It does seem fairly clear, however, that whatever the final adjustments may be in the foreign countries producing zinc, the American spelter industry, both from a mining and smelting point of view, has bright prospects for some time to come.

The effect of these changes on the Joplin mining district, the largest single producer of zinc ores in the United States and the largest producer of high-grade concentrate in the world, forms an interesting chapter in current history. The demand for spelter of the grade necessary for making brass for munitions naturally fell to those concerns whose product came principally from the smelting of high-grade zinc concentrate. The effect of this demand was felt on the Joplin market immediately after the declaration of war and the over-running of Belgium by the Germans. England needed spelter, and, finding it impossible to obtain it from former sources, turned to the United States. Prices for concentrate jumped from $38 and $40 to $50 per ton in Joplin; and thus began one of the greatest eras of production the Joplin district has ever known.

Following the long period of low prices in 1913 and in the first half of 1914, there had accumulated in the bins of Joplin producers surplus stocks amounting to 12,000 to 18,000 tons of concentrate. Simultaneously the rate of production had fallen to approximately 5000 tons per week, the major portion of which was coming from the smaller mines and richer ore deposits, from which profits could still be obtained even in the face of low prices. The large 'sheet-ground' areas were full of idle mines and mills; and these were the properties, too, from which come the large weekly outputs. Another singular condition was the fact that in the thin sheet-ground areas there were still standing some of the mills that had become monuments to the failure of concerns that had attempted to work ground containing less than 2% zinc. On a $40-market they were colossal failures: with a $75-market they offered opportunities for quick and large profits, because the development work was all done underground and the only expense was the repair to the plants before production at capacity was possible. As the zinc smelters turned to the Joplin district for their needed supplies of high-grade concentrate, they found there large surplus stocks to draw upon, a steady weekly output of 5000 tons, and, with an increased price, a potential output of 1200 to 2500 tons weekly.

The rapid increase in demand for 'brass-special spelter' soon used stocks of high-grade concentrate held by most of the smelting concerns, and caused those whose products had been confined to ordinary grades from mixed and low-grade concentrate to change their practice to turning out a better quality of spelter. Some smelters that had been taking large tonnages of low-grade concentrate restricted their contracts to the minimum, accumulated product in stock-piles, and began the purchase of high-grade concentrate and the manufacture of spelter suitable for brass-making. This action again was reflected in the Joplin district by an increased demand, and prices began to soar.

The only action looking toward the greater use of low-grade product was the importation of 14,000 tons of Australian concentrate, which was purchased on unusually good terms for the smelters, and did not realize sufficiently good returns to the sellers to induce them to repeat the experiment. Since then the tendency has been toward the use of high-grade concentrate wherever it is possible to obtain it.

In adition to the desire for concentrate of high-grade for making a good brand of spelter, the desire for maximum capacity on the part of the smelters has led to the increased demand for Joplin 60% zinc concentrate. A zinc silicate or carbonate product must carry 40% to be acceptable, while a sulphide carrying less than 50% is not being sought. Thus while many Western mines capable of producing a large tonnage of 40 to 50% zinc concentrate are finding that they cannot market their product, the demand upon the Joplin district is constantly increasing.

Responding to this demand, the Joplin district during the first six months of 1915 has shown a weekly production of 6230 tons of zinc concentrate, equivalent to 325,000 tons annually. Of this nine-tenths is sulphide that will average 57% zinc, and the remainder calamine that will average 40%. This shows an increase of approximately 20% in output for the half-year. It is safe to say that the momentum of increased activity due to increased demand and prices is just now at the point where it is being most felt, and the results are certain to be made more manifest in the second half of the year.

Practically all the mines in the 'sheet-ground' that are normally classed as going concerns at normal prices of $40 to $45 for concentrate are now working at full capacity. Every 'soft-ground' property capable of production at normal prices is also working at full capacity. When it became certain that the period of high prices had come to stay for the period at least of the war, those 'sheet-ground' mines, previously mentioned as "colossal failures," but now potential profit-makers,

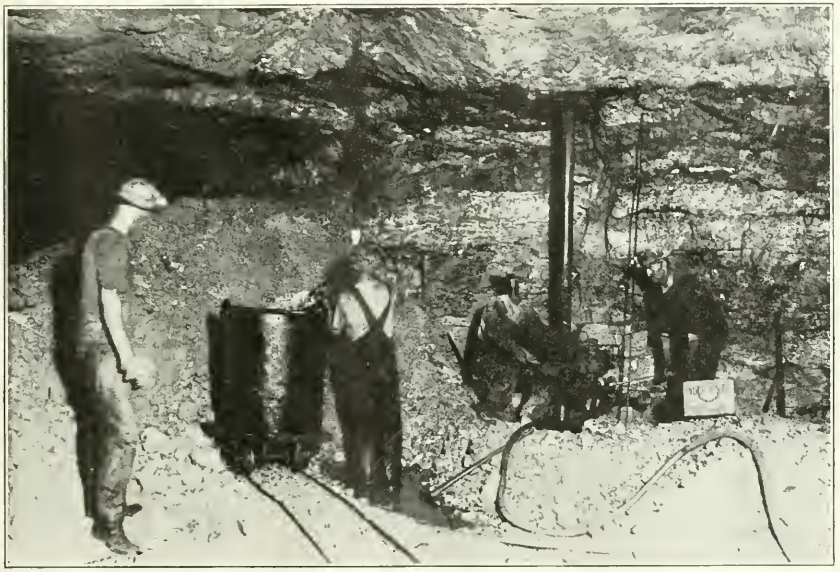
received attention. They are beginning to show in the production columns and before the year ends there will be a much larger list of active properties of this class. Their life, of course, will be confined to the period of high prices.

With a possible demand of 220,000 tons of export trade in spelter, the major portion of which will be for 'brass-special spelter,' there is no decrease probable in the demand that will be made upon the Joplin district for its high-grade concentrate until the end of the War. Granted that only half of the 220,000 tons was for high-grade spelter, the normal domestic use for which in brass-making is over 60,000 tons per year, this would consume more than the spelter possible to manufacture from the Joplin district concentrate, even if it yields 325,000 tons this year. When it is taken into consideration that the normal use will be enormously increased on account of the tremendous orders for American munitions and automobiles, the outlook is indeed promising for some time to come.

What is worrying the Joplin ore-producer more than anything else at the present time is the division, between the mine-owner and the smelter, of the profit represented in the increased price of spelter. Taking the price of spelter at 19 cents per pound, a ton of Joplin 60% concentrate yields approximately 1050 lb. spelter valued at $200. For this ton of concentrate the producer obtains about $90. It costs the smelter $14 to smelt it and put the metal upon the market, leaving a profit of $96 to the smelter. On the other hand, it costs the producer in the neighborhood of $40 to put the ton of concentrate in the bins, leaving him a profit of $50 per ton. While the producer is glad to have a profit once more, he is inclined to believe that the division ought to be nearer 50-50 than it is.

The rapidly increasing smelting capacity, as announced by the new additions to operating plants, and the building of new ones, is being viewed by the Joplin ore-producer with a great deal of joy, for it means a constantly better division of profit. Once the smelting capacity is established on a competing basis, the demand for concentrate will naturally effect a better relation between the profits of the mining and smelting ends of the industry.

On the other hand, the miner's fears are centred upon the building of a tide-water smelter that would utilize the zinc concentrate from Australia for re-export trade, and the resumption of imports of zinc ore from Mexico on a large scale following a settlement of the revolutionary conditions that have heretofore acted as a prohibitive tariff against that country.



IN A SHEET-GROUND MINE AT JOPLIN, MISSOURI, ORE AT 200-FT. DEPTH. NOTE THE 1000-LB. CAPACITY CAN USED THROUGHOUT THE DISTRICT.

Reduction of Manganese Ores. The reduction of manganese ores in a blast-furnace can be done directly or indirectly, according to H. Thaler, in *Oesterreichische Zeitschrift fur Berg-und Huttenwesen*. The furnace must be run hot in order to get the most favorable conditions for reduction and the fuel consumption increases with increase of the manganese content of the furnace charge. The slag contains 8 to 10% Mn and its basicity should be 0.8 to 1%; the loss of manganese by volatilization amounts to 7 or 8% in a 20% spiegeleisen. The ratio of silicon to manganese must not be too high, or reduction of silicon takes place.

Concerning Rock-Drills

By P. B. McDONALD

In *The Engineering Magazine* for July Mr. L. O. Kellogg contributes an 18-page discussion on 'Rock Drills in Mining.' This really tells what mining men would like to know about rock-drills, instead of the platitudinous pedantry of dry trivialities that discourages the reader in the customary article on the subject.

For the benefit of those who do not see *The Engineering Magazine*, the following condensed extracts are offered with a comment or two.

"On any particular job of shaft-sinking, driving, or stoping, it is often possible to get nearly as cheap results by hand work, particularly in remote situations, in the softer rocks, or at temporary jobs and doubtful prospects." [I would add here: where good hand-drillers are plentiful and not too high-priced. There is an English copper-mining company that has operated successfully by hand-drilling along the remote Newfoundland coast for two generations. It would not be difficult to bring coal for power-drilling from Nova Scotia by boat, but there is labor available for hand-drilling that is capable and cheap.] "Within only a few years large and important shafts have been sunk entirely by hand. Still, the machine-drill has considerably reduced mining costs by the indirect methods of making it quicker and easier. It has doubled the speed of sinking, quadrupled the speed of driving, and increased the tonnage broken per driller five or ten-fold. Next to the mine-pump the machine-drill has made modern mining modern."

"No gasoline or electric-drill has proved thoroughly satisfactory, although electric-drills are possibly successful in coal mining."

"The Leyner was the first American hammer-machine to make any great stir, and was developed in the West. It [the Water-Leyner or Leyner-Ingersoll] is especially available for flat holes, being not very widely used for shaft-sinking, since in such work the hole-bottom is not kept so clean and there is a loss in efficiency. In raising or in stoping where approximately vertical holes are required, not only is the [water] cleaning not necessary but on the contrary the sludge has a tendency to run down into the machine and make trouble." [The Calumet & Hecla uses Leyner-Ingersolls in inclined raises of about 40° where 'stopers' are not so convenient as in vertical raises.]

"The stoper followed the Leyner. The first machine consistently successful in this country was the Waugh, also a Western product. For over-hand stoping and raising, the stoper [essentially an unmounted, air-feed, hammer-drill] is the most highly efficient machine yet devised. Valveless stopers, such as the Ingersoll-Rand Imperial, are not gaining in popularity. It is simpler than a valve-actuated stoper, but less efficient and wears more rapidly." [Simplicity is a whole lot, but so is wearing quality.]

"The first automatically rotating stoper on the American market was put out by the McKiernan-Terry Drill Co. The second by the Cleveland Rock Drill Co., which type represents the most advanced design of any stoper, has a throttle-valve so arranged that in soft ground the rotation can be made rapid but the hammer-stroke light, while in hard ground, hard hitting can be obtained with any desired speed in rotation; that is, the rotation and the drilling hammer can be operated separately and at different speeds. Despite, however, this desirability of control and flexibility, such a type of stoper weighs much more than a hand-rotated stoper of the ordinary sort. Automatic rotation of stopers is an advantage when the hole is somewhat flat and the cuttings, not falling out readily, bind the steel in the hole. It is easier for the miner." [Under ordinary conditions it is not much of a bother for a miner to rotate a stoper by swinging by hand, especially as he hasn't to feed the drill ahead—the air doing that—and it rather keeps him awake. However, for inclined holes in irregular ground, the Cleveland machine is undoubtedly a blessing.]

"It is not unlikely that a stoper style of drill may establish itself for driving, using water and air to clean the hole, and differing from the Leyner essentially only in having air-pressure feed instead of hand cranking." [Possibly a plugger type rather than a stoper type for driving will evolve, so that 'push' feed by the miner will replace hand-cranking or air-pressure feed, obviating cumbersome rigging-up except 'fish-pole' mountings or rope suspension.]

"The first automatically rotated plugger to score any considerable success was the Jackhamer of Ingersoll-Rand, although the honor of putting the first machine on the market probably goes to the McKiernan-Terry Drill Co. The Cleveland 'Mucker' possesses the same separate engine and valve as the Cleveland stoper. The Ingersoll-Rand 'Bull Moose' is seemingly much like the 'Mucker' in construction." [Who selects these attractive names?].

"The quality of the drill-steel has not kept up to the progress in drills; particularly does drill-steel show up weak with hammer-drills. In a deep mine, it is calculated that every round-trip to the sharpening-shop for each piece of steel costs 10 to 15 cents. There is some promise in a detachable bit invented in Butte, such that a miner can carry bits for a working-shift in his pocket."

"What constitutes a good drill?

1. Speed because miners are highly paid workmen.
2. Standing-up to the work.
3. Lightness and convenience, because much depends on the miner liking his machine.
4. Low air consumption, not of so much account as the first three, because speed, etc., is more important than a little wasted air. The air-drill is an inefficient and extravagant machine at best. It uses an expensive fluid at full stroke; a 3½-in. piston machine requires when running probably 25 hp. to be taken off the motor-shaft of, say, a belt-driven compressor."

OIL PRODUCTION of Pennsylvania in 1914 was 8,170,335 bbl., averaging $1.906 per bbl. This was an increase of 253,033 bbl. but a decrease of $0.581 per bbl. in value.

An Electric Furnace for Melting Cyanide Precipitate

By W. P. LASS

*The gold precipitate from the zinc-dust presses in the cyanide plant of the Alaska Treadwell Gold Mining Co., Treadwell, Alaska, is treated, in the refinery adjoining, by the Tavener or lead-smelting method. About 3 or 4 tons of this precipitate, containing $40,000 to $60,000 in gold per ton, is produced monthly. It was formerly the practice to treat the by-products from this process, consisting of 2 tons of slag, 300 lb. matte, and 500 lb. refinery refuse, flue-dust, etc., in a 24-in. water-jacketed blast-furnace. This practice was discontinued in 1914 because of the difficulty of keeping the lead-well open when treating a high-grade lead product; of preventing the loss of gold in the flue-dust; and of avoiding injury to the general health of the refinery operators.

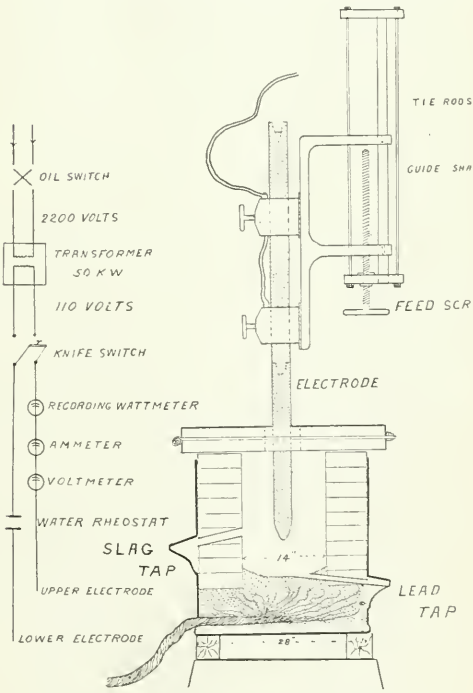
A plain single-phase electric furnace was substituted for the blast-furnace. This was constructed from an old steel acid-drum by cutting off the top and introducing a cable, made from strands of bare copper-wire, through the bottom and spreading the strands out fan-shaped on the inside of the drum. Powdered graphite, obtained by grinding old crucibles, mixed with 10% of cement, was tamped wet into the bottom of the drum, around and completely covering the copper wires. The graphite was carried up to the bottom of the furnace, or lead-well, and acted as the lower electrode. The sides were built up of ordinary firebrick, forming a melting-chamber 14 in. diam. by 20 in. high. The upper electrodes, of graphite or carbon, are 3 in. diam. and 40 in. long, arranged with joints enabling new electrodes to be connected without shutting down or wasting stubs. A screw-feed was arranged for raising and lowering the upper electrode.

The cover for the furnace had three openings, one for feeding the charge, one for the escape of gases, and one in the centre for the introduction of the electrode. It was later found more practical to enlarge this centre opening to 6 in. diam., to allow central feeding of the charge around the electrode. A 4-in. pipe connected to a ventilating fan carries off the escaping gases. The furnace is operated on the lighting-circuit through a 50-kw. transformer, 60 cycles, 110 volts. Later, a water rheostat, operated by raising and lowering one disk on another submerged in a barrel of water, was constructed to lower the voltage for use when starting the furnace, or when there was a bath of metal in the bottom of the furnace that would otherwise allow too much current to pass and thereby cause short circuiting.

The material to be treated in the furnace is mixed in the following proportions: Refinery by-products, 100 lb.; old reverberatory hearths, containing 60% CaO, 20 lb.; litharge, 20 lb.; coke, 2 lb.; scrap-iron, 3 lb. About 160 lb. of the mixture is added for a charge. The total amount of material added during the melt is 8507 lb., of which 5870 lb. is by-product material (old slag, the residue from burning old mill-launders, sweepings, etc.) of the following composition:

	%		%
SiO_2	40.1	Al_2O_3	2.0
Fe	16.0	S	3.6
CaO	16.1	Moisture	4.0
Cu	5.9		
Pb	3.0		96.4
Zn	5.7	Gold.....$1096.60 per ton	

Coke is added to the charge as a reducing agent, in sufficient quantity to reduce the lead. The charge is introduced into the top of the furnace through the central opening around the electrode, without removing the slab cover.



FURNACE FOR MELTING CYANIDE PRECIPITATE.

In starting, the furnace is operated as an arc-furnace, until it has become thoroughly hot. Then the charge, consisting of slag, brick-dust, etc., is added, the electrodes being raised as the load in amperes increases.

*A paper to be presented at the September (San Francisco) meeting of the American Institute of Mining Engineers.

until the entire chamber is filled with the charge and the upper electrode extends into the melt almost a foot. As the charge continues to melt the electrode is moved down or up, keeping the amperage reading as nearly constant as possible. The raising or lowering of the upper electrode decreases or increases the power consumption and thereby affects the amount of heat generated. At this stage the furnace is no longer operating as a simple arc-furnace, but has automatically transformed itself into a resistance type of furnace, the semi-fluid or molten charge acting as the resistant, the current passing from one electrode through the centre of the charge to the other. After the charge is in quiet fusion, which takes on an average 2 hr. 10 min., the power is turned off and the charge allowed to settle for 15 min. before tapping the slag. This allows the lead to settle, the furnace acting as a fore-hearth.

In operation, the molten lead and slag are tapped as in the blast-furnace. If the lead freezes it is melted by diverting current from the upper electrode and letting it pass through the lead, the tapping-rod playing as an arc on the side of the furnace or into the lead-tap. The operators use colored or amber glasses to protect their eyes from the glare of the electric arc.

OPERATING DATA

Total running time	128 hr. 40 min.
Average weight of charge added	160.5 lb.
Average fusion time of charge	2 hr. 25 min.
Total number of charges	53
Graphite electrodes used	1 per 24 hr.
Total power for 128 hr. 40 min	4440 kw.-hr.
Power used per hour	34.50 kw.
Power used per lb. of material fed	0.52 kw.-hr.
Power used per ton of material fed	1044.0 kw.-hr.
Acheson graphite used per hour	0.15 ft.
Material melted per hour	67.7 lb.
Material melted per 24 hr	1625.0 lb.

The only item of cost for flux is the coke, 2 lb. per 100 lb. of by-product material, or 118 lb. total, being used, since the old reverberatory hearths furnish the lime; the cupels from bullion refining, the litharge; and mill scrap, the iron. Both graphite and carbon electrodes are used, the former costing $2.95 each, and the latter $1.20. Power cost is less than 1c. per kilowatt-hour. The labor required for the operation of the furnace, including the work of charging and tapping, is one-half one man's time, when melting 1 ton in 24 hr. The furnace was constructed and put into operation by the regular cyanide-plant crew, without the aid of special electricians. The operation is so simple as to require no special training. Although the operators were unaccustomed to handling electrical equipment, no trouble has been experienced from electrical shocks, since the bottom of the furnace acts as the lower electrode, or grounded circuit.

The advantages of the electric furnace compared to the blast-furnace for melting high-grade gold slags are: A saving in mechanical loss of gold in flue-dust, because the melting is done in a quiet neutral atmosphere, instead of in a rising blast of air; the obtaining of a lower-grade slag, free from shot, by reason of the quieter melting action and the higher temperature obtainable, making a more fluid slag; the nicety of regulation of the melting temperature; the benefit to the general health of the operators.

Precipitation of Copper by Electrolysis

By R. R. GOODRICH

*In precipitation of copper from a solution by electrolysis the current should be proportional to the copper content of the solution. In completely precipitating the copper from a solution the operation is best conducted in a series of steps. Thus, for example, if the original solution contains 6% copper, it may be circulated through a series of 12 cells, the electrode area in each cell being 1, and $\frac{3}{4}$ of the copper present precipitated, the copper content of the effluent being 1.5%. This is then circulated through 3 cells, the electrode area of each cell being four times and the current density one-quarter that of the first cells. The effluent from these cells contains 0.375% copper, which is completely precipitated in a single cell with a cathode area eight times and a current density of one-eighth that of the first cells. Thus in the first cells three-quarters of the copper is precipitated, in the second set 3/16, and in the final cell 1/16. Any other ratio, such as 2/3, 2/9, and 1/9; 1/2, 1/4, 1/8, 1/16, and 1/16; or 1/4, 1/4, 1/4, and 1/4 may be used. In this way the current density may be adjusted to suit the composition of the electrolyte. It also makes possible a rapid rate of circulation of the electrolyte, which leads to high current efficiency. When using a carbon anode, depolarization, with consequent saving of power can be secured by the use of SO_2, but there is no depolarization with a lead anode. The depolarization, even with carbon anodes, does not exceed 45 to 65% of the theoretical amount; it varies with the current density, being a maximum at low current density. The method of introducing the SO_2 gas into the cell is unimportant, it should be present in sufficient quantity so that the electrolyte is saturated and some escapes from the surface. When it is present as a depolarizer a smoother deposit of copper is secured. Without its use a spongy deposit begins to form on the cathode before complete extraction is effected and there is also a rise in polarization. By the use of SO_2 the copper content of the electrolyte may be reduced to a trace, yielding a good firm cathode, without rise in polarization.

CHILE and the United States lead in the borax industry, with approximately equal outputs of borates, or boric acid, and borax, each producing from 40,000 to 50,000 metric tons of crude ores, mainly calcium borates. Turkey probably stands third in rank of production, with a reported average of 14,000 tons as boracite. Peru, Bolivia, Italy, Argentina, and India are also producers.

ELECTRIC STEEL PRODUCTION in Germany in 1914 totaled 89,336 tons; in Austria, 19,844 tons.

*Abstract of a paper to be presented at the September (San Francisco) meeting of the American Institute of Mining Engineers.

Recovery of Mercury From Amalgamation Tailing

By E. B. THORNHILL*

†In this paper on the recovery of mercury as sulphide, from the residues from the amalgamation and cyanide treatment of high-grade ores and concentrates, I shall not discuss the many reactions, chemical and otherwise, that take place in the general process, but confine myself more particularly to the methods of procedure.

I submit charts of two amalgamation-barrel charges, Fig. 1 and 2, which are self-explanatory. The flow-sheet of the high-grade and the mercury extraction plants is shown in Fig. 3.

In the amalgamation of high-grade silver ores and concentrates in strong cyanide solution, as practised in the Cobalt district, considerable mercury is contained in the residues from the amalgamation process. The greater part of this mercury is in the form of mercuric sulphide, from 5 to 10% only of the total mercury content being in the metallic state.

Attempts to eliminate this loss in the amalgamation process were made, but all resulted in a low extraction of the silver in the ore, and attention was then directed to the recovery of the mercury and from the residues.

The process developed at the Buffalo mines for this purpose consists in leaching out the mercuric sulphide with a caustic alkaline sulphide solution, then precipitating the mercury from solution with metallic aluminum. The equations for solution (1), and precipitation (2) are:

$$HgS + Na_2S = HgS.Na_2S \quad (1)$$

$$3HgS.Na_2S + 8NaOH + 2Al = 3Hg + 6Na_2S + 2NaAlO_2 + 4H_2O \quad (2)$$

Small-scale experiments showed that a complete extraction of the mercuric sulphide could be made by an 8 to 10 min. treatment of the residue with the alkaline sulphide solution. Advantage was taken of this fact in the commercial plant, by applying the solvent to the residue on the filter-leaf, as no agitation of any sort was required.

The operation of the commercial plant is essentially as follows: The residue in the pregnant cyanide solution is caked on a Moore filter-leaf of the usual construction and the cake washed free of silver solution with water. The basket is then lowered into the sodium sulphide solution and this solution drawn through the cake until the effluent shows only a trace of mercury. Usually 1 ton of solution per ton of residue is sufficient. This mercuric sulphide solution is pumped to a precipitating-tank and the mercury thrown down by adding granular aluminum to the agitated solution. Agitation is then stopped, the precipitate allowed to settle, and the clear solution decanted. The precipitate of mercury is then run into a small wash-tank by sweeping it through a hole in the bottom, by means of a raking mechanism similar to a Dorr thickener, pieces of old rubber belting being riveted to the bottom of the rakes. The precipitate is then washed with water by decantation and drawn off into a steam drying-pan. After drying, the fluid mercury and the powdered metallic portion are separated by raking the latter off with a hoe. The fluid is strained through a canvas and is ready to return to the circuit. The powdered material, containing approximately 75% mercury, is then retorted, and the mercury condensed in the usual manner.

The strength of the solvent is kept up to 4% sodium sulphide and 1% sodium hydroxide. Weaker solutions can be used with equally good results, but the quantity required was found to be directly proportional to the strength; that is, with a 4% sodium sulphide solution, 1 ton of solution would extract the mercuric sulphide from 1 ton of residue, but if a 2% solution was used, 2 tons would be required per ton of residue treated. The concentrated solution offers the advantage of less solution to handle and an economy of aluminum in the precipitation. The sodium sulphide used is the commercial salt costing $1.25 per cwt. in barrels f.o.b. cars Toronto.

The precipitant used is a waste product of aluminum-casting foundries, containing 75% aluminum, the impurities consisting of varying proportions of copper, silica, wood, waste, grease, etc., the grease being burned off before using the aluminum. About ¼ lb. of this material is used per pound of mercury precipitated.

It was anticipated that the sodium aluminate would accumulate in the solution to such an extent that some special means would have to be taken to remove it. This, however, has not been the case. Some aluminum, as hydrate, falls with the mercury on precipitation, and some is removed during the process of leaching, presumably as calcium aluminate, which collects on the filter-cake. This precipitation of the aluminum regenerates caustic soda so that the consumption of this chemical is reduced to $\frac{1}{10}$ lb. per pound of mercury recovered, instead of ½ lb. as shown by the theoretical equation for precipitation. Sodium sulphide is also regenerated in precipitation, but there is also a mechanical loss of approximately 20% of the solution used in leaching, as no water is used to recover the retained sulphide.

From May 1914 to March 1915, 37,650 lb. of mercury has been recovered at a cost of approximately 13c. per pound for labor and chemicals.

The laboratory methods of determining the mercury in

*Metallurgical engineer, Buffalo Mines, Cobalt, Ontario.

†Abstract of a paper to be presented at the San Francisco (September) meeting of the American Institute of Mining Engineers.

the different products of the process may be of interest. To determine the total mercury (both metallic and sulphide), 0.5 gm. of the material is well mixed with cast-iron filings, free from grease, and placed in a hard-glass tube, sealed at one end, with a contraction at about 2 in. from the sealed end. The mercury is distilled off, by heating the bulb containing the charge, and condensed in the tube just beyond the contraction. After the distillation is complete, the contracted portion of the tube is heated, the bulb portion pulled off, and the end of the tube sealed. The tube containing the condensed mercury is allowed to cool, filled one-half full of 0.1% KCN solution, and 10 to 15 100-mg. gold beads added. Each bead will amalgamate with about 1 mg. of mercury. The tube is shaken until all the mercury is amalgamated; the beads are transferred to a small porcelain cup, washed with water, dried with alcohol and weighed. After retorting off the mercury, they are again weighed. From 10 to 12 determinations can be made in one hour by this method and it is accurate enough for control of operations.

When it is necessary to know the proportionate amounts of mercury as metallic and sulphide, two 2-gm. samples are weighed out. One sample is digested with concentrated nitric acid and the other with a 10% solution of sodium sulphide. The mercury in the residue from each is then determined by the method just given.

The strength of the sodium sulphide solution is determined by titrating against a standard zinc chloride solution, using sodium nitro prusside as an outside indicator.

The mercury produced by this process is of exceptional purity.

Potash salts in notable amounts have been discovered in Permian strata in Texas, according to J. A. Udden, in Bulletin No. 17 of the University of Texas. The interesting feature of these deposits is that the potash salts occur in solid form, rather than as a brine, material containing 9.23% potash being found in one well at a depth of 900 ft. and 10½% potash in another at a depth of 1700 ft. The potash occurs in a red substance resembling carnallite that contains 14% KCl. It occurs in association with beds of rock-salt, at the top of the series, suggesting that it was produced by a long period of concentration of sea-water in which the point of saturation of the potash salts was finally reached.

Brick and tile industries of the United States in 1914 produced material worth $129,588,822, a decrease of $13,707,935. The principal clay product is common brick, of which 7,146,571,000 were made, valued at $43,769,524. This was a decrease of 942,219,000. Illinois is the leading producer. The fire-brick output was worth $16,427,547, a decrease of $4,199,575. Pennsylvania leads in this product.

Air-compressor plant at Balboa, Canal Zone, produced 120,760,010 cu. ft. of free air compressed to 105-lb. pressure during May.

Radium

Production of radium from Colorado carnotite ores by the U. S. Bureau of Mines, in connection with the National Radium Institute, has passed the experimental stage in its new process and is now on a successful manufacturing basis.

According to Charles L. Parsons, who is in charge of the radium investigations of the Bureau, the cost of one gram of radium metal produced in the form of bromide, during March, April, and May of the current year, was $36,050. This includes the cost of ore, insurance, repairs, amortization allowance for plant and equipment, cost of Bureau of Mines co-operation, and all expenses incident to the production of high-grade radium bromide. Radium has been selling at from $120,000 to $160,000 per gram.

The cost of producing radium in the small experimental plant during the first few months of the Bureau's activities was somewhat higher, but not enough to seriously affect the final average. The public, however, should not infer that this low cost of production necessarily means an immediate drop in the selling price of radium. The Radium Institute was fortunate in securing through the Crucible Steel Co. the right to mine 10 claims of carnotite ores belonging to the latter, this being practically the only ore available at the time. Since then new deposits have been opened. These are closely held, and, according to the engineers employed by the Bureau, the Colorado and Utah fields, which are much richer in radium-bearing ores than any others, will supply ore for a few years only at the rate of production prevailing when the War closed the mines. The demand for radium will increase rapidly. The two or three surgeons who have a sufficient amount of this element to enable them to speak from experience, are obtaining results in the treatment of cancer that are increasingly encouraging as their knowledge of its application improves. A few more reports like that presented to the American Medical Association at its recent meeting at San Francisco will convince the medical profession of the efficacy of radium. Mr. Parsons considers that under all the circumstances that have come to his knowledge it does seem that the Government should make some arrangement whereby these extensive and rich deposits may be really conserved for the American people.

The 10 carnotite claims being operated by the Radium Institute at Long Park, Colorado, have already produced more than 796 tons of ore averaging over 2% uranium oxide. The cost of ore delivered at the radium plant at Denver has averaged $81.30 per ton. This included 15% royalty, salary of Bureau of Mines employees, amortization of camp and equipment, and all expenses incident to the mining, transportation, grinding, and sampling of the ore.

A concentrating plant for low-grade ores has been erected at the mines, and is successfully recovering material previously rejected.

Concentrates

Readers of the Mining and Scientific Press are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

Concentration ratio in the Alaska Gastineau mill is approximately 500 : 1.

Crude oil is of two kinds, paraffine base and asphalt base, and varies from 11 to 46° Baumé.

Churn-drill holes are drilled between levels at the Old Dominion mine, Arizona, to improve ventilation.

As the proportion of volatile matter increases in bituminous coals, so does the difficulty in burning the coal under boilers.

Boilers from an old stamp-mill at Silver Mountain, Alpine county, California, are being used as culverts in repairing the State highway.

Logwood is still used in wool-dyeing, as it is cheap and produces a desirable black that can only be produced by aniline dyes of a higher cost.

At Joplin, Missouri, concentrate is called 'ore'; at Black Hawk, Colorado, concentrate is called 'tailing.' Such are the vagaries of local terminology.

Mechanical stokers, by feeding coal to the grates, gradually permit of a uniform distillation of volatile gases, and hence are well adapted to high-volatile coals.

Round timber is sometimes hewed so that chute-lining may be spiked to it, but in heavy moving ground a chute of square timber stands better and lasts longer.

Stellite is a new alloy containing cobalt and chromium, well suited for fine cutlery. When hardening metals are added, it has an advantage of from 20 to 100% over high-speed tool-steels.

Sheaves and drums should be kept smooth and in alignment to prevent undue wear of ropes. The grooves should be of sufficient size so that the rope will fit easily into them without binding on the sides.

Conglomerate at the Calumet & Hecla mine requires more powder in blasting than does the amygdaloid formation. Over a pound per ton is necessary for the former, and under a pound for the latter.

Nitric-acid manufacture was begun in this country by Carter & Scattergood, of Philadelphia, in 1824. The industry did not attain any importance until 1862, when the discovery of nitro-glycerine and other high explosives opened a new field for it.

Antimony penta-sulphide, known to the trade as crimson antimony, in its commercial form contains 15 to 17% of free sulphur, and for that reason is largely used in vulcanizing rubber. The resulting product is red, but not all red rubber contains antimony.

Combined carbon increases the strength of steel up to 0.9%, after which it has a weakening effect. It decreases the ductility, toughness, malleability, magnetic power, and electric conductivity, increases the hardness both before and after quenching, and increases the brittleness.

Graphite or silica alone do not make so good a pigment as when combined. The silica of silica-graphite paint adds durability and supplies just enough 'drag' to prevent too thin a coat. Silica should be broken with the graphite so that particles of each cling to the other and do not settle when mixed with oil.

Coke contains all of the ash and about half of the sulphur originally present in the coal from which it was made. All the phosphorus of the coal is present in the coke; there are also present a considerable amount of nitrogen and water, and small amounts of hydrogen and oxygen that cannot be driven off by heat.

Dried kelp (seaweed), contains ordinarily about 15% potash, 2% nitrogen, and 1.5% phosphoric acid. It can be used as a fertilizer alone, or in the manufacture of complete fertilizers. The total fertilizer value of a short ton of dried kelp, is $6.68, in addition to the potash content, which is worth $9.07. It costs $3.83 per ton for production of the kelp.

Alundum, which is used extensively as an abrasive, is made at Niagara Falls, New York, by fusing calcined bauxite in an electric furnace. Alundum is especially efficient for the grinding of steel forgings and castings. Only the best grades of bauxite are used in the manufacture of such chemicals as alum, aluminum sulphate, and aluminum salts, as freedom from oxide of iron is desirable for such purposes.

Magnesium chloride can be separated into magnesia and hydrochloric acid by the application of heat. Many patents have been taken out for processes. The high temperature demanded, the cost of labor required in removing the residue from the furnace, and the fact that the end product is a mixture of magnesia with oxy-chloride of magnesium (the latter having no value) have so far defeated all attempts to evolve a practicable process.

Centrifugal compressors are being increasingly used at mines. They have several points of advantage, namely: no valves, plungers, pistons, heavy moving members or wearing parts; they deliver air without pulsation and in such a manner that the volume can be regulated by merely opening or closing a valve, without excessive rise of pressure; they require less receiver-capacity, little space, light foundations; wear and repairs are practically eliminated; the amount of oil and supplies used is trifling, and because of their great simplicity they can be satisfactorily maintained in operation by unskilled attendants.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

MELBOURNE, AUSTRALIA

AUSTRALIA AND THE WAR.—METAL PRODUCTION AND CONTROL.—ARRANGEMENTS FOR DOMESTIC CONTROL OF METAL SALES.—SPELTER.—IRON PRODUCTION.

One of the effects of the War in Australia promises to be a huge development in the industrial enterprise of the country. This is consequent upon the strongest force in nature, that of sympathy. And it also is a remarkable illustration of how silken cords are in reality the strongest of ties. The political ambition of Great Britain ever since the fatal mistake that led to its rupture with the United States has been to develop freedom in government, to impose no fetters on the communities that might be classed as dependencies. Consequently the spectacle is presented today of a self-governing community like that of the Commonwealth of Australia actually seeking to force the motherland to adopt a line of action that at the first glance appears to be contrary to all established British ideas of freedom.

One of the regions in which German organization was reaping its greatest triumph before hostilities began was Australia. For some reason never properly explained, the British smelter and metal-buyers failed to realize the mineral potentialities of this continent. At the outset the Briton held a grasp on the lead industry of Broken Hill and controlled the market for copper and tin, but he never took a close personal interest in Australia. Perhaps it was due to the visit of Schnabel in the early nineties that German eyes were opened to the possibilities of Broken Hill. Or it might have been that the successes attained by those who controlled the base-metal outputs of important regions in North and South America led the German house of Merton to combine its interests in Frankfort and then with a magnificent financial backing to start out to win trade in British communities. Anyway, for the past decade the British metal-buyer has been absolutely shouldered out of Australia, except perhaps in respect to tin. The houses that have been enabled to secure this domination have been the Metallgesellschaft, Aron Hirsch, Beer-Sondheimer, Goldsmidt, and some of the lesser Teuton lights. So skillfully have these firms conducted their operations that no one realized how strong was their hold until Australian sentiment determined that it would have nothing that was German. Then it was found that the Broken Hill Proprietary Co. was held by an agreement with the Lead Convention under which it had to sell through a firm in London that had co-operated in business matters with the Merton houses of Frankfort. The copper trade was discovered to be in German hands exclusively and the zinc business was regulated by three or four firms that were either absolutely German, or were German-controlled. Put into figures, the situation was that exports of from £12,000,000 to £15,000,000 were for all practical purposes in the hands of German houses or co-operating firms. This was discussed editorially in the PRESS of July 10. As this trade was steadily growing, is it any wonder that when war broke out, one of the most astute representatives of Frankfort capital exclaimed, when discussing the German war-lords: "Oh, the fools to destroy by war the victories of peace!"

The instant effect of the War was to thrust idleness on a large mining population in Australia. This arose from the existence in all the contracts for the purchase of crude ore, concentrate, and mine products of a clause suspending the operation of the contract until the termination of hostilities. The mines and the smelters were cut off from their markets and consequently had to shut-down. Thus an important problem was presented not only to the managements of the mines but to the Labor Government of the Commonwealth. The aptitude of the Britisher to rise to an emergency was soon displayed. Mines re-opened, and gradually arrangements were perfected for the disposal of the products. Here, however, the suspension clause in the agreements between the German buyer and the mines began to be the cause of great discontent. This discontent extended when it was discovered that the Broken Hill Proprietary was tied down under its agreement with the Lead Convention in such a way that it had to run

grave risks if it sold to the agents of British purchasers save through London as agents specified in its Convention agreement. When the Federal authorities learned of this, they did not waste time. Military law gives wide power; they searched the offices of high and low to find how the business was being handled and whether there was any secret trading with the enemy. Nothing unpatriotic was found, but sufficient facts were forthcoming regarding the German control of the trade to induce the Federal Attorney-General to decide not only to ask the Legislature to abrogate all contracts between Australian companies and enemy aliens, but to induce him to request the British authorities to move in the same direction when the domicile of a company working mineral land in Australia was in Great Britain. If that suggestion had been accepted there would have been an end to the whole of the contracts held by Continental firms in Australia, but the British Ministry has declined to go as far as asked. In Australia, however, the Labor Government was moved to take action, with the result today that a Federal enactment provides for the dissolving of all metal contracts with enemy aliens. To make the position still more secure, the State governments have each promised to pass a similar measure. As they are Sovereign States in all matters in respect of which they have not ceded authority to the Commonwealth, the nail in the coffin holding the contracts will be driven home very firmly.

It must not be assumed for a moment that the Continental interests involved take the situation at all kindly. Their representatives have not dared openly to resist such legislation, but the friendships they have built up, based on mutual interest with firms in London and in Australia, have proved strong. However, no voice has been raised against this legislative voiding of contracts, though such an act in itself is opposed to the spirit of freedom that is supposed to live in the folds of the Union Jack.

With this discovery of alien interests, new organizations had to be created. The first evolved was one intended to merge the smelting business of the Broken Hill Proprietary Co. at Port Pirie into that of a new concern to handle not only the lead concentrate of that company but those of the South and the North companies as well as those of any other Broken Hill mines that might care to join the new combination. Already the Zinc Corporation has come into the fold, and it is thought that other leading companies will share. At present the works have a capacity of about 4000 tons of lead per week, but they will be enlarged so that all the lead concentrates of the Broken Hill district can be treated, except those that find their way to the Newcastle works of the Sulphide Corporation. The North and the South Broken Hill companies alone can furnish over 2000 tons of 70% lead concentrate per week, and if the other companies should come in it will mean that the German houses will lose the smelting of ore and concentrate reresenting an output of over 200,000 tons of lead per annum. This metal will be marketed by the new company. That raises the question as to how the marketing will be conducted when the War is over. If Germany should win, there is little doubt as to what will be done. If it should lose, will British policy and sentiment be so strong as to compel the merged company to act away from all association with the German firms that formerly constituted the leading factors in the Lead Convention? If this happens will their American associates enter into a war of competition with the Australian company? Many people think that self-interest will prevail and that patriotism will be relegated to the dust-bin.

The zinc position is different. The only distillation works in Australia belonged to the Broken Hill company and form a part of the new Port Pirie smelter. Their capacity was under 5000 tons per annum. The zinc contents of all the concentrate produced at Broken Hill represents about a sixth of the world's production, and it is estimated that it would take between £3,000,000 and £4,000,000 to erect works capable of dealing with the output. The lives of the mines are not sufficiently assured to justify such an expenditure. So the companies have sent agents to the United States and to London to find out if the ore will be bought in those countries. It is only of late that American buyers have quoted a favorable price, but no large shipments have been made to that country, the cost of freight proving prohibitive. On the other hand, the British government has not been inclined to depart from its old established policy of non-interference with private enterprise by subsidizing the construction in England of works for the production of spelter, but there appears to be some indication of a change of policy. Of late inquiries have been made from London for zinc concentrate, and it is thought the intention may be for Britain to co-operate with France in enlarging zinc distillation works in the latter country to meet national needs. If that be done, the result may be the abrogation of contracts between Broken Hill companies domiciled in London and enemy subjects that otherwise would be revived directly war ceased.

Last, and most important, comes the iron and steel enterprise of the Broken Hill Proprietary Company. This concern has expended a large sum in erecting, at Newcastle in New South Wales, a large plant for the treatment of iron ore obtained from the Iron Knob and the Mammoth ore deposits in South Australia. Over 100,000,000 tons of exceptionally high-grade iron ore is developed here. The trade to be supplied is worth at least £7,000,000 per annum and although the company's works are not of sufficient extent to enable it to meet this business, still a most determined attempt will be made to capture it. The question that arises is whether labor, which now dominates politics in Australia, will permit one of the oldest planks in its platform—the nationalization of the iron industry—to be smashed by this private corporation. Will it try to buy the works or will it start in opposition? Whether this be done or not the world can be certain that Australian policy will be to protect the new industry against outside dumping. This, of course, will mean cutting British, Continental, and American iron-masters out of the market unless they care to come inside the tariff wall, take up iron ore deposits, and establish themselves in this country.

LORDSBURG, NEW MEXICO

Mogollon District.—New Railroad.—Lead Concentrator.—New Companies.—Wages at Chino.—Empire Zinc and Santa Fe Gold and Copper Mines.

Shipments of gold and silver bullion from the Mogollon, Socorro county, are being made regularly from Silver City. The Ernestine company has been granted a permit from the state engineer to take water from the south fork of Silver creek for a storage-capacity tank. At Socorro on July 26, the property of the Mogollon Gold & Copper Co. was to be sold at auction to satisfy a judgment for $416,626 given the Equitable Trust Co. of New York. No bid for less than $100,000 was to be considered, and the special master could postpone the sale at the request of the plantiff or a majority of the bondholders. A $17,000 school is being erected at Mogollon. It will be completed for the fall term. The roads between Mogollon and Silver City are in a deplorable condition and almost impassable in places. Several projects for new road construction are under consideration by both Grant and Socorro counties, but none have yet materialized.

By August 15 the Arizona and New Mexico railway will be hauling ore from the mines in the Virginia district, three miles southwest of Lordsburg, over the new spur connecting with the main line. Work on the grading commenced several weeks ago, and has been continued rapidly. At present the preliminary track is as far as Shakespeare. Several of the larger cuts have been completed and two bridges have been erected. The company did not let contracts, but did the grading itself. The tractors hauling ore between Lordsburg and

the 85 mine, by Rowan and Downey, will be moved to other places on the completion of the spur.

The dry concentrator at the Waldo lead mine at Lordsburg started on July 20. It is making a satisfactory recovery. The present mill is merely a test-plant, if successful a larger one will be built.

New mining companies recently incorporated in New Mexico are as follows: Southwestern New Mexico Mining Co., of Hachita, capital, $150,000, fully subscribed, incorporators are T. J. Barnes of Hachita, and J. D. Russell and J. Boyd of Sweetwater, Texas; Estrella del Norte Mining Co., incorporated by Las Cruces and El Paso men, capital, $1,000,000, A. S. Brice of El Paso is statutory agent; Lee Russel and Edward Burch of Hurley, have incorporated the Rip Van Winkle Mining Co. and will operate mines at Fierro.

The gold properties of the Wildcat Leasing Co. of White Oaks, Lincoln county, have been taken under option by Richard Wightman and associates of New York. Messrs. Stanton and McDonald completed the transaction.

The Chino Copper Co. has announced a general advance in wages of all its employees of approximately 10%. The scale will be continued as long as the selling price of copper is at 17c. or above.

The Empire Zinc Co. operating the Cleveland and Utter mines at Pinos Altos, Grant county, have received a 250-hp. Snow, two-cylinder, four-cycle, crude-oil burning engine which will be installed at the new power-house at the Cleveland mine.

The Santa Fe Gold & Copper Co., operating in the San Pedro district of Santa Fe county, is producing from 8 to 10 tons of copper matte per day, according to reports from that place. The matte is being refined in Omaha. J. E. Bergh is superintendent, and A. Gibson, is smelter superintendent. From 300 to 400 men are now employed at the mines and reduction works.

MEXICO CITY, MEXICO

General Conditions in Southern Mexico: Explosives, Currency, Food, Prices, Mine Taxation, Land Speculators.

The hostilities between Carranza and Zapata have been the chief obstacle to mining since October, 1914. When a mine is visited by a troop of either faction, it means a depletion of explosives, draft animals, and food. A few of such visits are enough to discourage the activity of the most strenuous operator. Even in places where police protection is assured, as in most of the state of Oaxaca, three serious famines have kept the mines closed, as there has been a lack of explosives, of small change, and of food. For over a year there has been no train service from the central dynamite mills in Durango, and the factions have discouraged the private importation of powder for fear it might fall into hostile hands. Explosives can only now be imported by special consular permit, and its date of arrival even then can never be foretold in advance.

When Carranza first arrived in August, 1914, he brought with him a great quantity of paper money which dropped exchange within a month from 30 to 20c. gold, for the peso, but as most of the new paper was in ₱1 bills and there were also plenty of *cartones* (cardboards) for small change, there were no pay-roll difficulties. But in December, after Carranza had moved to Vera Cruz, the printing-presses confined themselves to large bills only, and small bills and *cartones* became so scarce as to command a premium of 5 to 10%. The banks could afford no relief; they had troubles of their own. Forced by Huerta to suspend specie payment on their notes in 1913, they were obliged in 1914 to close many of their branches, to curtail expenses, and to refuse to accept any new accounts. In March, 1915, they refused any longer to accept deposits even from their old clients, and to pay checks in anything but large Federal bills. The banks of issue have been hoarding their own notes for several years, and notes of the National or London banks now command a premium, in Federal bills, of 40%. As it is against the law to ship money by mail, the express companies no longer receive money for transport, and no postal orders or bank-drafts are now issued, one has to carry his wealth when traveling on his person. Mexico has thus reverted in its financial facilities to those of the Aztec confederation.

The food famine is the most serious of all. In spite of the scarcity of farm hands and the destruction of green grain, to make fodder for cavalry horses, there would probably have been no famine except for exportation. Not only have the military chiefs collected large export-taxes in gold upon all material sent away, but they have themselves seized and exported food by the shipload in order to satisfy their insatiable hunger for guns and cartridges. Another result of this suicidal policy, of starving their own people, was a plentiful supply of recruits, but no financial surplus, as all applicants, even boys of 14, were gleefully enrolled and guaranteed wages of ₱1.75 per day. The present misery of the civilian masses who have had no chance to share in the 'blessings' of the Revolutionary militarism may be judged from a comparison of prices, quotations being given in Mexican money:

	October, 1914.	July, 1915.	Increase, %
Maize, per litre	₱0.07	₱0.50	614
Beans, per litre	0.07	0.50	614
Peas, per litre	0.07	0.50	614
Flour, per kg	0.20	1.00	400
Rice, per kg	0.35	1.75	400
Sugar, per kg	0.20	0.80	300
Coffee, per kg	0.80	2.00	150

Even at these prices, maize, the Mexican staff of life, can only be obtained in uncertain quantities. Most mine operators have given up the struggle, and their workmen have either taken refuge in the army or on some plantation, where they can be paid with home-grown food. Thus the difficulties of both the pay-roll and the food-market are avoided.

Of course, with the peso at 8c. gold, the equipment of new mines with machinery becomes impossible for companies whose treasury cash is in pesos. But in mining centres already fully equipped, like Pachuca, the fall in exchange has been a godsend, particularly to struggling companies like the San Rafael y Anexas, as it has meant that the chief item in the cost of production, native labor, has been reduced to a bagatelle. The native miners at Pachuca have managed to struggle along, so far, on little more than the old wage-scale. The American officials have been given half their salaries on a gold basis, and when they change their gold for Mexican paper they feel like millionaires.

Carranza's new schedule for mineral-land taxation, which has been condemned by so many American miners, is really a step in the right direction. The former annual tax of ₱6 per hectare (1 hectare = 2½ acres) for the first 25 hectares, and ₱3 per hectare for any excess area, was entirely too low to hinder speculators, and in 1910 the industry was beginning to feel the throttling effect of having all the likely ground in every district being held by a few dogs-in-the-manger who did no work themselves, but charged others dearly for that privilege. The real burden of the new tax-scale does not consist in its high rates (they only range from ₱12 to ₱24 per hectare), but in the requirement of their payment in gold. With the peso at 8c. gold, the ₱24 rate means ₱150 in paper, and for any miner whose cash has been in Mexico since 1913, and has consequently depreciated in value along with the peso, the new scale means a real advance from ₱3 to ₱150, or 5000%, and probably the speedy loss of his holdings. The new rates are specially unfair to those who are prevented by revolutionary conditions from operating their properties.

The mine-owners of Oaxaca refused to pay taxes under the new schedule, and as the state seceded from Carranza's rule in April, they have not yet had to do so. However, the state certainly needs some higher taxation, as mineral-land specula-

tion has been rampant there for the past decade, and Americans are the chief offenders. In the Magdalena lead-gold district, the Villa Alta, Tatolopana, and Taviche silver districts, the San Fernando lead district, and the great Zaniza iron belt, the likely ground is all occupied by a few individuals or companies who do little besides hold on strenuously to their paper titles to undeveloped ground.

JOPLIN, MISSOURI

High Zinc-Blende Prices Continue.—Lack of Mill Capacity.—Important Development by the Picher Lead Co.—New Work at Neck City.—Tuberculosis.

Abnormally high prices for zinc-blende continue throughout the Missouri-Kansas-Oklahoma district, the basis range being from $80 to $110 per ton for concentrate assaying 60% metallic zinc, at the close of July. At these prices operations can be conducted profitably in many old mines that could not be worked successfully at lower figures. Efforts of operators are largely devoted to getting their mines on a productive basis as soon as possible. There is an unusual amount of drill prospecting underway. Prospects now being opened with drills and new shafts cannot reach a productive stage for some months to come, but so firm is the faith of mining men in a continuation of high prices that they are opening new properties in the hope that when they become producers ore will still be in strong demand. New companies find it impossible to procure old mills, as every plant in the district is in use. Those that were on abandoned leases have been removed to more profitable areas, and so strong has been the demand for treatment plants that not only have old properties become producers again, but machinery dealers have been taxed to meet the demand for new equipment. Especially strong has been the demand for plant for small prospects, hundreds of which are being opened in every part of the district. Upright boilers of about 40-hp. capacity have been at a premium for the past two months, and carload lots of this size have been sold in advance, and purchasers are anxiously awaiting their arrival.

In the north Miami, Oklahoma, district the Picher Lead Co., which for the first time has started mining, has five large shafts into ore at a depth of 260 to 275 ft. Work has been started on four additional shafts. The scene of this activity is eight miles north and slightly east of Miami, or about four miles northeast of Commerce, which is the main centre of the north Oklahoma district. Still north of Commerce is the little town of Cardin, which is developing into a fair-sized mining community. North and east of Cardin is Picher, Oklahoma, which is just cutting its first teeth as a mining community. The first hotel, the initial barber-shop, the pioneer grocery-store and the original pool-hall of Picher have just been ushered into existence, while close by the new derricks of the shafts that already have been sunk loom bright against the background of the gray prairie, and still newer lumber marks the places where other derricks will be constructed. Machinery for the first big plants of this company has been ordered and some of it has arrived at Baxter, Kansas, the nearest railroad point to Picher, from whence it will be carried overland. Bad roads, caused by continuous rains, have prevented the hauling of the machinery at an earlier date.

In the Neck City, Missouri, district one large new concentrating-plant, the Black Hawk, has just been completed and is producing concentrate from the tailing of an old mine that was operated on this land. The Black Hawk is under the management of G. L. Cole. It is situated on a lease of the Calumet Lead & Zinc Co. The mill has a capacity of 300 tons. Mining operations will be conducted at a depth of 200 ft. Pumps are now at work draining the ground.——Another mine in the Neck City district that is attracting interest is that of the Longacre-Chapman Co., where operations have been resumed following the catastrophe that killed four men, in addition to holding four others imprisoned for several days. The catastrophe was caused by a flood that filled the drifts with mud and water. After the work of rescue had been finished and the last dead body removed, a new prospecting company was formed, comprising several of those who had been imprisoned in the mine, and work is now being conducted at the same spot where the four met their death. A rich orebody is being worked at this place.——V. Long & Co. are operating the old Annalinda mine. A new hopper is being constructed at this plant.——At the old Rubber Neck a shallow lead mine is being opened by Compton Brothers.

How flint-dust in the lungs causes tuberculosis was explained at a recent meeting of the Southwest Missouri Mine Safety and Sanitation Association by A. J. Lanza, past assistant surgeon of the U. S. Public Health Service. His address was illustrated by X-ray plates. The Association is devoting its efforts toward making working conditions in the mines of this district more healthful.

The United States Smelting Co., of Boston, is procuring desirable mining leases throughout the district. On a lease just procured at Reeds, Missouri, a 300-ton concentrating plant is being erected. This company acquired control of smelters at La Harpe, Iola, and Altoona, Kansas.

Another cave-in of ground occurred near Joplin last week, several miners being injured. It is to be hoped that rapid ore extraction is not responsible.

CRIPPLE CREEK, COLORADO

Ajax Mill to Resume.—Vindicator and Golden Cycle.—Strong Mine.—Drainage.—Tenderfoot Hill.—Independence.

It is reported that the Ajax mill will soon resume operations. The mill has been idle for some time because of insufficient ore to make operations profitable. Since the mine was recently thrown open to lessees on the split-check system, there is enough ore to warrant re-starting the plant.

On July 26 the Vindicator company distributed $45,000, the regular quarterly dividend of 3c. per share. Net earnings in the second quarter of the year were about $400,000. Surplus profits are being used to pay the Golden Cycle purchase notes, $490,000 out of $1,250,000 having been paid. The cash balance is maintained at over $200,000. Good ore has been opened on No. 18 level of the Golden Cycle. In reaching this a new shoot was opened for over 180 ft., assaying $30 to $40 per ton. Two new shoots have been opened on No. 17. The shaft is being sunk to 1900 feet.

The Strong Gold Mining Co. has completed sinking its shaft to 1350 ft. Below this there is a sump 28 ft. deep. A station will soon be cut on No. 13 level, and immediately after development will be started.

An increase in the flow of water from the portal of the drainage-tunnel was noted last week. The breast of the tunnel has apparently pierced the rib of tight ground immediately adjacent to the Elkton mine and the broken volcanic area. From now on the water should rapidly recede from the shafts at all affected by this tunnel. Favorable results from the lowering of the water-level are already materializing. The Elkton shaft will be sunk again in the near future. The Portland company expects to start sinking its No. 1 shaft soon after August 1.

In the region of Tenderfoot hill, the new deposit at the Ella W. continues to produce a large tonnage of medium-grade ore. Prospecting in that vicinity has greatly increased during the last few weeks. While several developments have been reported nothing persistent has been uncovered.

There are about 25 sets of lessees at work on the Independence mine. A number of these are breaking a good grade of ore. Others are doing development work. Several of the latter have excellent prospects of opening up new orebodies within a short time.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

Final figures of the territory for 1914 are as follows, according to the U. S. Geological Survey: gold, $15,764,259, an increase of $140,000; copper, 21,450,628 lb., a decrease of 209,330 lb.; total value of metals, $19,118,080, against $19,476,356 in 1913. Total to date, $268,150,000, of which gold accounts for $244,156,000.

The Governor of the Territory, J. F. A. Strong, returned to Juneau last week after a month's tour including Fairbanks and Nome. He summarized his impressions as follows: "I found the general conditions all through Alaska excellent. There is a spirit of hopefulness abroad that is characteristic of Alaska, and none of the depression we read about below. There is a good deal of unemployment, it is true, but there is no place in the country that I know of where a man always has a real chance to get a living as he has in Alaska. As we went down the Yukon I was particularly impressed by the improvement in the towns along the river. It looked as if every town on the river had a cleaning-up week. The buildings have been re-painted in many cases, and the streets have been cleaned up. The old reckless camp spirit seems to have mellowed into an admirable brand of civic pride."

The territorial mine inspector, W. Maloney, arrived at Nome on July 10. He recently visited nearly every district in the country outside of Seward Peninsula, and found conditions flourishing, particularly at Ruby and Iditarod.

Juneau

Hot weather has resulted in making the woods dry, streams low, and numerous fires starting on the mainland and on Douglas Island.

In the suit of V. Vansteen against the Alaska Gastineau company for $50,000, damages for injuries received in driving the Sheep Creek adit on July 15, 1913, Judge Jennings decided in favor of the defendant. If the accident had occurred 15 days later the case would have come under another statute. The 'fellow-servant' law was abolished by the first Legislature in 1913.

The Ready Bullion shaft is to be deepened from 2200 to 2400 ft. on the incline.

A great deal of work is being accomplished at the Alaska Gastineau property to prepare it for a large output of ore, ultimately 10,000 tons per day. During this period it is necessary to break about $2^1/_2$ times as much ore as is milled at present, about 3000 tons per day. This has a tendency to lower the average gold-content. The estimated cost of mining, 75c. per ton, has been lowered. The mill treated the following tonnage: March, 40,000; April, 57,000; May, 73,500; and June, 90,800. The cost of treatment is only 60% of what it was at the beginning. Construction of the other units of the plant continues. The Sheep Creek dam overflowed on June 18.

On July 24 work commenced driving a 1300-ft. tunnel to tap Annex lake 150 ft. below the surface of the lake. This will save the expense of making a dam, as the lake is fed by about 20 streams. From the mouth of the tunnel an 8000-ft. pipe will carry water to the Gastineau company's power-plant.

The Alaska Treadwell output in June was affected by an accident; it was as follows: ore crushed, 51,006 tons; gold by amalgamation, $75,786; gold from cyanidation, 1217 tons of concentrate, $62,099; total value, $137,885; operating expenses, $73,004; construction charges, $25,610; net profit, $37,892. The average yield was $2.70 per ton. Development totaled 326 ft. The stock of broken ore decreased 32,178 tons.

ARIZONA

The Southwestern Mine Safety Association will hold its annual field meet at Bisbee on September 6 and 7. If $1600 can be raised it is intended to send the winners of the state contest to the meet at San Francisco on the 23rd and 24th. Seven mining companies have agreed to donate $200 to the fund. No. 2 rescue-car of the U. S. Bureau of Mines will be at Bisbee during the contest. All works at the mines will be suspended on the day of the field meet. Wallace McKeehan is secretary-treasurer.

Cochise County

Pay-days on July 20 and 21 were the largest in the history of the Warren district. The three large companies are operating at high pressure.

At Tombstone, the Bunker Hill company is treating 60 tons of $7 ore per day. Old tailing is also being treated. Pumps are working at the shaft where a large sum was spent on drainage years ago. About 300 men are employed in charge of E. Grebe.

Gila County

On about August 1 churn-drilling was to be started at the A. S. & R. Co.'s property at Christmas, recently acquired from the London-Arizona company. An aerial tram will carry ore to the Hayden smelter.

Mohave County

It is reported that within a year the old McCracken silver mine, 40 miles south of Yucca station, will be treating 500 tons of ore per day. A mill of that capacity is being planned. The mine is estimated to contain ore worth $700,000, the average being 16 oz. per ton. C. E. Finney of Los Angeles is largely interested.

Pima County

Eleven contractors bid for construction of the Calumet & Arizona company's 44-mile railway from Gila Bend to its copper mines at Cornelia. The successful one was James H. Maxey of Yuma. The line is to be completed by January 10, 1916.

CALIFORNIA

Eldorado County

A 10-stamp mill is to be erected at the Frog Pond mine in the Garden Valley district. C. Waite and T. J. Dayley are largely interested.——The Ward and Union gravel mines near Placerville have been bonded to J. Wilmans.

Inyo County

Mining activity in the eastern part of this county may be summarized as follows: Zabriskie, on the Tonopah and Tidewater line, is a busy distributing centre for about 15 mines. The two largest are the McCausland and Carbonate. The former gold mine is at an altitude of 3500 ft. in the Funeral range; the mill is 135 ft. below sea-level. Other mines in the district are the Acacia, Confidence, American, Rusty Pick, Ibex, Wonder, Rob Roy, and Gladstone. Copper and talc deposits are receiving attention.

Placer County

At the old Herman mine, five miles from Westville, 20 men are working. Three veins occur in the mine, and 4367 ft. of development has been done. By the end of the year it is expected that the 30-stamp mill will be in operation.——With its small stamp-mill and a Marks centrifugal mill, the Excelsior mine near Forest hill will soon be producing 150 tons

of ore daily. The present 25 men are to be increased to 50.—— After being idle for many years the Big Oak and Rising Sun mines near Colfax may be re-opened.

San Benito County

Near Hollister, L. H. Day and H. U. Underwood are preparing to develop a large deposit of high-grade barium sulphate.

Shasta County

On July 31 at Gas Point the Shasta Dredging Co. received by wagon from the railway at Cottonwood, 14 miles, a screen for its new boat. It is 6-ft. diameter, 31 ft. long, and weighs 18.5 tons. This is the largest piece of machinery ever hauled in the county. Twelve horses were required.

The Ora Vista dredge of L. Gardella at Oroville, Butte county, is to be dismantled and moved to his Clear Creek property, four miles south of Redding.

The Golinsky copper claims, two miles west of Kennett, have been bonded to the Mammoth Copper Co. A good deal of ore has been sent to Utah from them.

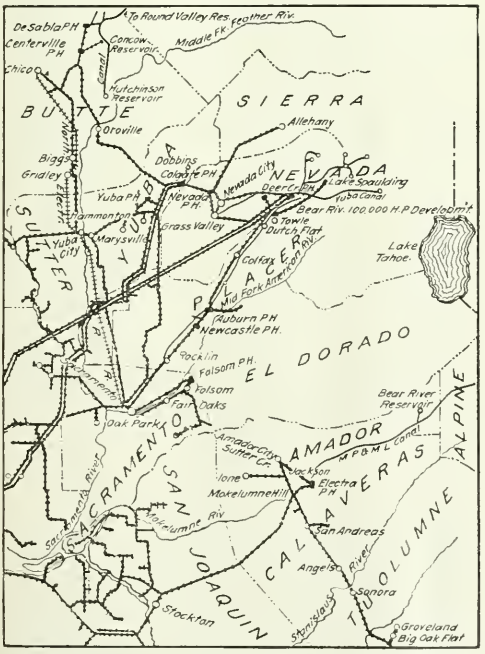
Sierra County

In the erection of the new 15-stamp mill at the Plumbago mine by R. Hathaway, the contractor, the material was hauled 28 miles from Nevada City. Work commenced on June 1; on the 26th the plant started work.

Tuolumne County

The Golden Key mine near Sonora is to be re-worked on an extensive scale in charge of F. A. Wallin. The ore is opened by adits.

The annual report of the Pacific Gas & Electric Co., for the year ended December 31, 1914, has just been issued. Of its



MAP SHOWING POWER-LINES OF PACIFIC GAS & ELECTRIC CO. SUPPLYING MINING AND DREDGING DISTRICTS.

revenue of $8,759,449 from the sale of electricity, power sold to mining and dredging companies yielded $591,314, an increase of $33,852. Sales of water for power were $58,909, but the amount credited to mining is not stated.

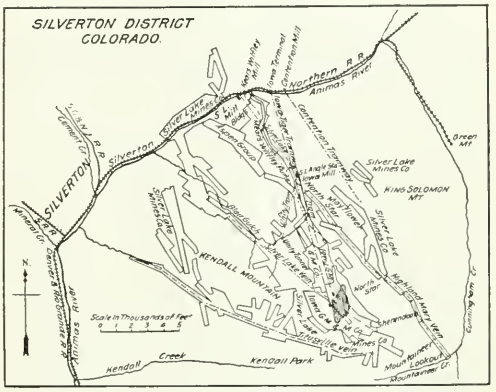
COLORADO

Clear Creek County

Leases at the Waldorf mine at Georgetown are employing about 40 men. A large tonnage of ore is being extracted.

San Juan County

In the *Silverton Weekly Miner* of July 16 the Silver Lake property is described. It has been a consistent producer for 20 years. There are about 200 claims in all, covering 1500 acres, at an altitude of 12,300 ft. From approximately 18



miles of underground workings the output is $11,000,000. The Silver Lake and Titusville lodes are probably the most persistent, but the ore is generally low-grade. The former vein contains lead, silver, and zinc; the latter, copper, lead, zinc, and gold. Many of the district veins junction with the Silver Lake. Work at present is mostly confined to the Titusville claims. The mill consists of two units, one of 300-ton capacity for the Silver Lake-Titusville and the one of 150 tons for ore from the Aspen mine. The property is worked by several different lessees. The Americau Ore Flotation Co. has a lease of the mill. A flotation plant is working successfully. Concentrate is sent to the Durango smelter. D. L. Thomas is in charge of the plant, with P. M. Collins as foreman. Mears and Wilfley are treating tailing from the old mill at a new plant.

Lake County (Leadville)

Iowa gulch is fairly active after several years of dullness. Lessees at the Lillian are shipping gold and zinc carbonate ore; about 250 tons in July. The Clear Grit is to resume. Doris and others are receiving attention.——Lessees in the Laplander adit have finished the difficult work of driving the 200-ft. cross-cut from the main adit to a winze which produced rich silver ore years ago.

Pitkin County

At Aspen the Doctor Leasing Co. has arranged a contract worth $100,000 for marketing the large tonnage of zinc ore in the Doctor mine. By November 1, 5000 tons of not less than 30% ore must be delivered. G. Runtz is in charge.

IDAHO

The itinerary of Bureau of Mines rescue-car No. 5, in charge of John Boardman, is as follows:

Mullan, was at the Gold Hunter mine, July 26 to 31; Mullan, at Morning mine, August 1 to 7; Burke, 8 to 14; Mace, 15 to 21; Success, 22 to 28; Kellogg, August 29 to September 11; Wallace, 12 to 15; and Spokane, Washington, (shops for repairs) September 16 to October 9.

Blaine County

During July the Wilbert mine, in the Dome district, shipped 16 cars of ore to Utah, netting $34,502 at the smelter. The freight was $3187.

Clearwater County

To meet the increased parcel-post rates on ore after September 1, miners will send by parcel post to Stites, on a branch of the Northern Pacific line, and thence to smelters by rail. It was found that the new charges would result in closing down some mines.

Lemhi County

During July the Pittsburg-Idaho mine, near Gilmore, shipped 32 cars of ore to Utah, worth $40,922. A new shoot is being developed between 400 and 600 ft. Lessees are doing well.

Shoshone County

It is reported that the Interstate-Callahan company offered $450,000 cash, and another larger sum, for the Ray-Jefferson property. The offers were not accepted.——It is also rumored that the Hercules company and A. S. & R. Co. have compromised on the smelting contract dispute.

On August 4, the Bunker Hill & Sullivan Mining & Concentrating Co. paid dividend No. 215, of $81,750. This makes a total of $16,364,250.——The Caledonia company will pay 3c. per share, or $78,150, during August. A car of lead-silver ore, weighing 35 tons, recently netted $6500, the richest lot ever sent from the Coeur d'Alene. A winze below the 900-ft. level has opened 8 ft. of ore, some of which assayed 180 oz. silver per ton.——The Snowstorm Mining Co. will surrender its option to buy 650,000 shares in the Missoula Copper Co. to the National Copper Co. for $27,000, the last named to continue payments on the shares to the Missoula. The National mill at Mullan will treat ore from the Missoula.

In the Mullan district are three copper mines which promise well in the future, namely, the Carney, Reindeer-Queen, and Carbonate Hill. Long adits have been driven into them, with good ore showing. A mill is contemplated for the last mentioned, in charge of A. Haden.——Fourteen miles east of Mullan the Richmond company is shipping copper ore. The property is well developed and equipped. C. Heidenreich is manager.

MICHIGAN

The Copper Country

The Isle Royale mine is now producing about 2400 tons of ore daily. Half of this goes to its own mill. The average copper-content is about 13 lb. per ton.——The Calumet & Hecla has resumed all construction work stopped last August.

The Calumet & Hecla's smelter at Hubbell has 22 furnaces in blast. The re-grinding plants have resumed, a temporary power-supply being secured from the Ahmeek turbo-generator. ——A large number of men are busy making foundations for the leaching plant.——Work at the Tamarack re-grinding plant has been suspended.——The Copper Range Consolidated is receiving bids for fifty 50-ton new steel ore-cars. They are of a new type, constructed from the design of M. N. Barker to carry ore or stamp sand. The sand is used for filling underground.——The Osceola is producing nearly 5000 tons of ore per day.——At the 'little' Tamarack mill two stamps are to be added.——The third new head at the Isle Royale will be ready in a week.

The Michigan College of Mines has issued its year book for 1914-1915, with announcement of courses for 1915-1916. It consists of 116 pages, tables, and three good maps.

MISSOURI

Jasper County

Production of the Missouri-Kansas-Oklahoma district last week was as follows: blende, 4883 tons; calamine, 207 tons; and lead, 521 tons. The average price was $99.93, $60.89, and $59.96 per ton respectively. The total value was $532,083. Choice concentrate realized $115 per ton. Good calamine is in strong demand. Lead ore remains unchanged.

The Castle Rock district, northeast of Joplin, once a centre of small mines, is receiving renewed attention. Zinc ore is cut at from 60 ft. downward.

MONTANA

Missoula County

The Intermountain Copper Mining Co. is to acquire the property of the Amador Mining Co. near Iron Mountain. A two-mile flume has been repaired, foundations for a 100-ton mill are completed, and the lower workings of the mine are to be drained and re-timbered. The shaft is 700 ft. deep. Oscar Nordquist, of Wallace, Idaho, is in charge.

Silverbow County

The report of the North Butte company for the second quarter of 1915 contains the following: ore and precipitate treated, 86,978 tons; copper yield, 4,490,324 lb.; silver, 239,513 oz.; and gold, 270 oz. Development totaled 2920 ft. The new electric plant at the Granite Monntain shaft is hoisting everything, the Speculator shaft being idle. The Edith May vein was driven on at 2200, 2600, 2800, and 3000 ft. Work at the last level proved the continuity of the ore from 2800 ft. Results on the Snowball vein were satisfactory. The property is working at 90% capacity.

The Butte-Alex Scott company is installing a Nordberg hoist of 3000-ft. capacity. The daily production is from 150 to 175 tons of high-grade ore.—The Butte-Ballaklava is shiping about 250 tons per day. At 1600 ft. ore has been opened for 320 ft.——The Anaconda company has started suit against the Butte Copper Co. for a partition or sale of the Robert Emmett No. 1 and 2 claims. The plaintiff owns 66⅔, and the defendant the remainder. F. A. Heinze once controlled the property.

NEVADA

Elko County

Ten miles northwest of Tuscarora an important discovery of gold-silver ore is reported. The nearest railroad point is Elko.

Esmeralda County

The estimated production of the Goldfield Consolidated in July is as follows: Ore mined, 33,388 tons; gross extraction, $275,000; operating expenses, $170,000; and net realization, $105,000.

On September 1 the Jumbo Extension will distribute 7½c. per share, equal to $116,250.

Humboldt County

According to the *Review-Miner* of Lovelock, from within a radius of 30 miles of the town, three cars of antimony ore has been shipped, realizing $5500.

Nye County

Seven mines at Tonopah last week produced 10,407 tons of ore worth $213,286.——Better ore is being opened at 1350 ft. in the Extension.——Lessees at the Montana shipped 107 tons of $31.60 ore to the West End mill last week.——At 1155 ft. the Mizpah Extension is driving on 3 ft. of ore.——At the East End sinking has been resumed.

TEXAS

Brewster County

(Special Correspondence.)—T. B. Weir and J. C. Scott, who are reported to be interested in quicksilver mines of California, recently visited the Terlingua quicksilver district in the lower part of this county, close to the Rio Grande. They acquired a large tract of land upon which outcrops of cinnabar are found. They propose to start mining operations as soon as the necessary machinery and other equipment can be installed. A 40-ton furnace will be built when sufficient ore has been opened to justify it. The Terlingua district is reported by engineers who have examined it to be one of the richest. The deposits have been little developed. The fact that the district is 90 to 100 miles from the nearest railroad has handicapped development considerably.

Terlingua, July 18.

UTAH

Juab County

The Tintic district produced 163 cars of ore last week.——Electric pumps are working at 1600 ft. in the Gemini.——Diamond-drilling is still being done at 1900 ft. in the Iron Blossom.——The Bingham Mines Co., which controls the Eagle and Blue Bell has acquired the Victoria mine adjoining the latter.——At the Tintic Standard four jigs are treating 35 tons of ore per day.

CANADA

British Columbia

On September 10 the Standard Silver-Lead company will distribute 2½c. per share, equal to $50,000, after a year's lapse. The total to date is $1,600,000. As regular shipments of lead and zinc ore are being made, monthly payments will be kept-up.

At Grand Forks the Granby company has eight furnaces in blast. About 250 men are employed there, also 600 at the mines at Phoenix. The company has bonded the Gloucester copper claims for about $100,000.

Ontario

(Special Correspondence.)—At the Hollinger the decline in grade is due to the policy of the management of developing all ore that will yield a profit over working costs. Ore is now being extracted from 14 or 15 veins, the smaller being invariably of lower grade than the main vein. It is probable that the grade of the ore treated will be gradually lowered and a larger tonnage from many veins treated. A winze is now down to 950 ft.; good ore is being mined at 800 feet.

Porcupine, July 28.

At the McIntyre, at Porcupine, No. 3 shaft is down 500 ft. A station has been cut there. Sinking continues to 600 ft. At this depth at No. 4 shaft there is from 12 to 20 ft. of ore. Profits in April, May, and June were $23,777, $23,928, and $21,326 from 7870, 8360, and 9180 tons respectively. The company has purchased the Pearl Lake mine for $200,000.——It is rnmored that work may be resumed at the Jupiter.——Development at the Imperial is very satisfactory. At 100 ft., $13 ore is being extracted.

MEXICO

El Oro

A report dated London, July 9, 1915, includes the following remarks on work at the Esperanza mine, El Oro, Mexico, from January 1 to March 31:

On account of revolutionary activities, railway service was discontinued on January 26, since which date no bullion shipments have been made nor supplies brought in. El Oro became the centre of such activities about this time which came to a crisis on February 25, at which time the place was completely abandoned, thus shutting down all mills in the district. Mining operations were also discontinued, but underground prospecting was continued, 1892 ft. of development being done in the Esperanza. Conditions have improved only slightly since the above mentioned date, and no supplies have been obtained. Ten tons of cyanide and other supplies were brought down to Acambaro during the period under review, and remain there safely stored. Only a few important development programs were started again. These are being carried on, for instance, work on the Descubridora vein, and the sinking of winze No. 16 to the 15th level. General repairs in the mine are being kept up; all stopes having been properly filled. Diamond-drilling continues also on a reduced scale, due to the small stock of repairs and stones on hand. The work of re-opening the Sirio shaft continues whenever possible. In the mill some important changes are being carried on with the idea of improving the work of the Merrill slime-presses, and further plant is being installed to improve the cyanidation of San Carlos and Descubridora ores. It should be said that the mail, telegraph, and railway services are cut practically all the time.

PERSONAL

Gerald Sherman is at the Hotel Oakland.

J. Parke Channing was at Butte recently.

Charles M. MacNeill is at the Fairmont hotel.

J. V. N. Dorr is spending a month at Berkeley.

J. W. Foss, of Phoenix, is visiting San Francisco.

W. B. Fisher, from Boston, is in northern California.

W. H. Aldridge has returned to New York from Arizona.

T. Bruce Marriott has returned to London from the Argentine.

James F. Kemp is taking a holiday on Lake George, New York.

F. R. Weekes has moved from New York to Darwin, California.

Edwin E. Chase has returned to Denver from northern Ontario.

Charles E. Arnold is here on a holiday from Miami, Arizona.

W. L. Cumings, of the Bethlehem Steel Co., is sailing for Chile shortly.

Horace V. Winchell has returned to Minneapolis from British Columbia.

F. Sommer Schmidt and Henry Krumb have been to Latouche island, Alaska.

Rensselaer H. Toll, now mining at Carson Hill, Calaveras, visited the Exposition.

E. C. L. Bartow of Philadelphia has been visiting the San Juan region of Colorado.

Charles W. Wright, now at Washington, will return to Sardinia early in September.

Warren D. Smith, professor of geology in the University of Oregon, is here for ten days.

Benjamin Madew has been appointed consulting engineer to A. Goerz & Co., of London and Johannesburg.

F. W. McNair, president of the Michigan College of Mines, was here during the week, after a visit to Butte and Salt Lake City.

Frederick L. Hoffman has been visiting the chief mining centres in connection with his study of hygiene and sanitation in mines.

Schools and Societies

The fifty-first meeting of the American Chemical Society will be held at Seattle, Washington, August 31, to September 3, inclusive. A complimentary dinner by the science faculty of the University of Washington to the members of the Council, followed by a business meeting, will be held on August 30. There will be sessions for reading papers, and excursions are planned.

(Special Correspondence.)—As mentioned in the Press of July 31, the Lake Superior Mining Institute meets at Ironwood on September 6, 7, 8, and 9. The visit to the Cuyuna range will be the first of the society. The district is the last of the six Lake Superior iron ranges to be discovered. A lot of development has been done, but owing to low ore prices little ore has been shipped. The Institute was originally organized as an annual 'getting-together' of officials of the iron mines, but in recent years machinery salesmen and people affiliated with mining have joined. The annual meeting is looked forward to by men both in the copper country and iron ranges. A number of interesting papers are to be read and discussed this year, as well as the excursions and first-aid meet.

THE MARKET PLACE

Weekly Summary of Metal Prices and Notes on the Markets.

Metal Prices

San Francisco, August 5.

Antimony	35 —35¾
Electrolytic copper	20½—20¾
Pig lead	5 50— 6.45
Quicksilver (per flask)	$95
Spelter	23 —23¼
Tin	39
Zinc-dust, 100-kg. zinc-lined cases	No quote

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, August 5.—The copper market is lifeless; the lead market is steadily falling; the spelter market is dull, there being no buyers, and prices are merely nominal.

COPPER

Prices of electrolytic in New York, in cents per pound.

June	56.43	49 03	Dec.	49.27	....

Silver has been to a record low price. On July 31 a steamer took about 750,000 oz. to China. Over three tons of Mexican dollars arrived at Bisbee, Arizona, on July 30, from China. This metal is probably for Cananea, where wages are paid in this coin. Speculators in New York are reported to be buying silver for a future rise. The Nipissing sent 250,509 oz. to London last week, a total of 511,673 oz in July. The Buffalo sent 263,943 oz. to New York for storage. This company has sold no metal since the War started. Stocks in London are about 20,000,000 oz. Continental support has been limited. Samuel Montagu & Co. on July 15 wrote as follows: "The tone has been without animation, and were it not for the scantiness of supplies, it would have been difficult to maintain prices. The abstinence of the Indian Bazaars has been again a noticeable feature. The market is so small that a little revival of demand from that quarter would cause an immediate rally in prices. In addition to reasons previously given for their lack of interest, may be added a deficiency of rain in certain districts of India. At so early a period there is no need for serious apprehension, but as the monsoon was rather late in arrival, a certain amount of nervousness might arise. China has been more inclined to sell than buy, and the weight of absorbing silver has fallen mainly upon Continental and other buyers apart from the East.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending			
July	7 95.00	July	21 95.00
"	14 95.00	"	28 95.00
		Aug.	4 95.00

Monthly averages.

	1914.	1915.		1914.	1915.
Jan.	39.25	51.90	July	37.50	95.00

May	33.29	39.28	Nov.	33.51	....
June	30.72	40.26	Dec.	33.60	....

On August 4 tin was quoted at 35.12 to 35.67 cents.

ANTIMONY

This metal affords some contrast to the others. It is fairly active, with prices easy at 35.25 to 36 25c. for both Chinese and Japanese. This firmness is noticeable, when the weakness in other metals is taken into consideration, especially as antimony has advanced more than any other since the War began.

Eastern Metal Market

New York, July 30.

There is practically no change in the metal-market situation since last week except that prices have declined. The threatened strike at the plant of the Remington company at Bridgeport failed to materialize; this is also true of the threatened general strike of the machinists. While the labor leaders report gains in the ranks of the unions, none of the plants in the vicinity of New York making munitions are having trouble. It is reported that the men are growing restless, but so far it is more or less of a waiting game. Two of the New Jersey plants have granted a 10% wage increase; others are rumored to be about to follow. At Boston one plant has closed down following the walk-out of a number of men; at another, controlled by the same interests, the workmen, while arguing for shorter hours and more pay, have taken no decisive action. In the meantime the large Bliss plant, which was reported as one that would be closed down, is still working both day and night.

Orders for war material requiring brass, lead, and other non-ferrous metals are still being placed in this country. A $3,000,000 contract for brass-shell cases for the Italian government has been placed with a Chicago company. This order calls for 1,250,000 shrapnel shell-cases, and is in addition to one for 500,000 brass-shell cases received from the Russian government about two months ago. A contract for small shells, rifles, and rifle-cartridges is reported as being practically secured by a Pittsburg manufacturer of bolts, nuts, rivets, and lightning-conduit from the Russian government. The value of this contract, which is the second largest received from that country, is $68,000,000. It is expected that most of the work will be sublet, as was the case with the $3,000,000-shrapnel contract received early in the year from the same source. The bullets called for will, in all probability, be made at the Remington plant.

In iron and steel lines the market developments of the week include an order for 220,000 tons of bars for shrapnel for the French government, and there are inquiries for 100,000 of bars for war munitions for domestic and foreign plants before the trade. It is estimated that 20 to 25% of the current output of the leading steel companies is represented in war materials. Pig iron has become firmer as a result of higher levels being established in the steel lines.

COPPER

As was reported last week, prices, although nominal for the most part, have a sagging tendency. There is no new business of any great amount and buying is very small. On the other hand, consumption continues on a large scale. Most of this is for war orders, and a further inquiry for 50,000 tons is reported. Little credence is, however, given to the report. The domestic demand is somewhat limited and prices are therefore nominal. Large quantities of copper must still be bought to fill munition contracts, but these buyers apparently are cautious in making purchases and are proceeding slowly. When this buying movement is started there will, of course, be a rally, but until then the market is quite likely to remain quiet. Prices have declined from 19c., cash, New York, for electrolytic on July 21 to 18.50c. Second-hands are offering the metal as low as 18c., although it is hard to hold the market steady. Large producers, however, predict a return to the 19c. level in the not far distant future, and are not offering the metal under that figure. Lake copper has been steady at 22c. for high-grade brands, although some have been quoted as low as 19c. The exports July 1 to 29 amounted to 14,588 tons.

The increase in the production of copper by four large properties in April, May, and June is shown clearly in the following table, compared with the yields (in pounds) in those months of 1913 and 1914:

	1915.	1914.	1913.
Utah			
April	12,015,148	13,133,779	9,834,894
May	14,053,765	13,616,993	10,312,695
June	14,730,912	13,268,106	11,637,949
Nevada Consolidated			
April	4,710,684	4,880,043	5,650,608
May	5,271,756	4,959,589	5,933,275
June	5,124,480	4,483,175	6,344,863
Ray Consolidated			
April	5,333,387	6,277,693	4,514,565
May	5,107,717	6,495,719	4,495,217
June	4,341,127	6,226,536	4,392,612
Chino			
April	3,027,548	6,109,888	4,046,813
May	6,442,977	5,666,881	4,067,486
June	6,984,977	5,656,102	3,876,533

ZINC

The prices for this metal are still on the down grade, due to increased production coupled with poor demand. While definite figures are lacking, it is known that the production has increased, the rate at the present time being, it is said, 100,000 tons greater per year than on January 1. The substitution of black and other sheets for the galvanized product has also exerted its influence to depress the market. Between the small size of the domestic inquiries and the absence of any foreign business, which the producers anticipated would sustain the market, there is nothing of great interest in this market. During the past week the price has declined 1.50c. It is still almost impossible to secure the special brass-mill grades at 30c. Exports from July 1 to 29, inclusive, total only 4241 tons, a very low figure compared with any other month since September 1914.

LEAD

The easy tone last week again prevails, and there is no noticeable improvement. The market is ruled almost entirely by re-sale lots due to the heavy deliveries by the leading interest on old contracts. The absorption of these lots is difficult, as the demand is light. The price of re-sale lots has declined to 5.50c., New York, and 5.40c., St. Louis, but producers are confident that the market will not go much lower. They base this belief on the ground that consumers must soon enter the market. It remains to be seen, however, how much foundation there is for this feeling, meanwhile dealers are offering some of the leading brands at the low prices. The exports for the month, including July 29, have been 2203 tons.

TIN

What has been said about the other metals applies with equal force to tin. The market is very dull and weak, and there have been no manifestations of activity for the past week. All the business that has been done, and that is but little, is in spot metal. Buyers, who look for still further declines in prices, do not show much interest in the market, although some attractive offers have been made in future shipments from the Straits. That the large independent consumers or tin-plate makers have covered for their requirements for the entire year is a feeling that continues to gain ground. This would seem to indicate that the business done in the latter portion of May and through June was greater in volume than was believed at the time.

MINING DECISIONS

Severance of Minerals by Map Dedication

A reservation of mineral rights in a dedicatory map of a townsite subdivision will not avail the dedicator or its successors in interest as against lot owners under a deed containing no reservation of such mineral rights. The whole title to the land passed by the deed in general form, even though the grantor may have made a prior dedicatory severance.

Hyde Park Investment Co. *v.* Glenwood Coal Co. (Iowa), 153 Northwestern, 180.

Conveyance of Minerals—Creates Taxable Interest

An instrument "granted, bargained, sold, and conveyed" to the grantee all the oil, gas, coal, and minerals under a certain tract on land in consideration of the payment of stipulated royalties and compliance with certain conditions by the grantee. Held, that this constituted a conveyance of an interest in the realty which was subject to taxation in the lands of the grantee, and not a mere usufructuary right or privilege taxable against the grantor as a part of the land.

Texas Company *v.* Dougherty (Texas), 176 Southwestern, 716. May 21, 1915.

Mining Contract—Fraudulent Representations

A prospective purchaser engaged an expert miner to examine a mine for him and relying on his favorable report, purchased it. It appears that the sellers washed the dirt away from the ore, thus giving it an appearance of an untrue proportion of pure ore, and represented that the mine would yield an exaggerated percentage of pure ore. It did not appear that the miner who examined the property for the purchaser was deceived by the representations or had appraised the property as more than a 'possible mine.' Held, that the purchaser, after trying to operate the mine and finding it a failure, could not recover purchase installments already paid upon abandoning his contract, as there was no showing of any fraudulent inducement which was relied upon by him on making the purchase.

Greenstreet *v.* Walsch (Missouri), 176 Southwestern, 1062. May 24, 1915.

Location Notice—Amendment Cures Defects

Certain ground was located as the Lafayette claim in 1901, but was forfeited and abandoned in 1902. In January 1903 it was re-located as the Eagle No. 2 claim, but the location notice failed to state that it had been located as abandoned or forfeited ground, a requirement prescribed by Section 3241, Civil Code of Arizona (1901). In 1907 the land was again located by adverse parties as the Oversight claim. In 1912, the Eagle No. 2 locators posted and recorded an amended location notice setting forth the statement omitted from their original location to the effect that they were locating forfeited or abandoned ground. They then applied for patent and the Oversight locators adversed and brought suit. Held, that as the Oversight locators were strangers to the original Lafayette title, they could not claim protection under the Arizona Civil Code section above cited, which was intended to provide notice to claim-owners of re-locations made on their claims under claim of forfeiture. Moreover the amendment of the Eagle No. 2 notice in 1912 related back to the original location and cured the defect if any existed. The Oversight claimants, although they were intervening locators were not affected in any of their rights by this amendment. Judgment for the Eagle No. 2 locators.

Copper Queen Consolidated Mining Co. *v.* Stratton (Arizona), 149 Pacific, 389. June 12, 1915.

RECENT PUBLICATIONS

Latin American Monetary Systems and Exchange Conditions. By Joseph T. Cosby, manager foreign department of the National City Bank of New York. P. 31. An abstract of this will appear in another issue of the Press.

District of Ungava. Extracts from reports on this territory recently added to the Province of Quebec, under the name of the Territory of New Quebec. P. 208. Ill., map, index. Mines Department, Ottawa, Canada, 1915. The area is 351,780 sq. miles, added to Quebec's 351,873 sq. miles. Gold, silver, copper, iron, and other minerals occur.

Map of Helena Mining District, Montana. 42 by 62 in. Also index to map, 32 pages. The Engineering Corporation, Helena, 1915. A note on this was published in the Press of July 24.

Mineral Resources of New Mexico. By Fayette A. Jones. Bulletin I. P. 77. Map and catalogue of minerals. State School of Mines, Socorro, New Mexico. This was reviewed in the Press of July 24.

The Little Buffalo Basin Oil and Gas Field, and the Grass Creek Oil and Gas Field. By F. F. Hintze, Jr. Bulletin 11. P. 120. Ill., maps. The state of Wyoming geologists (L. W. Trumbull) office, Cheyenne, 1915.

Les Minerais de Fer de la Province de Quebec. Gisements et utilisation. Par P. E. Dulieux. P. 243. Ill., plans, index Service des Mines, Quebec, 1915.

Report of the Royal Commission on the mining industry at Broken Hill, New South Wales. P. 862. Government printer, Sydney, 1914. Price £1, or $4.80. This is a voluminous report containing besides much data on sociological conditions in this lead-silver-zinc district, 24,381 questions and answers covering every phase of mining contracts, ventilation, drilling, hoists, wages, stoping, and labor disputes, occupying considerable space.

EDITORIAL

T. A. RICKARD - Editor

THE TRUE interest of the American people lies in the restoration of peace.

ALASKA, which was bought from Russia for $7,200,000 in 1867, has produced $244,156,000 in gold since the date of the transfer to the United States.

MEXICAN affairs are making progress. The administration at Washington seems fully awake to the importance of bringing the present impasse to an end. In our next issue we hope to be able to comment on real progress toward a settlement.

DEPRESSION in the silver market is causing the mines at Cobalt to store their output of metal and to restrict their production of ore, in the hope that the end of the War will cause a rise in price. This is dangerous, for it is not so much the War as the by-production of silver in the extraction of copper that is exerting a depressing influence.

TANGANYIKA CONCESSIONS is gaining respect as a copper producer. In 1914 the output was 92,381 tons of ore yielding 10,722 tons of copper, while working two furnaces on average. For the first half of 1915 the output was 6932 tons of copper, working three furnaces. Next year two more furnaces, increasing the existing capacity by 30 to 35%, will be available, so that an output of 25,000 tons of copper is promised.

A GOOD example of the falsity of much of the industrial data connected with the War are the two opposite reports, first that the people of Germany are selling their copper utensils to the Government at the full value, not of the metal but of the articles; second, that the German supply of copper exceeds 2,000,000 tons, that is, more than double the domestic production, plus imports, for an entire decade. The only thing of which we are sure is that Germany will be voracious for copper when the War is ended.

BY the operation of a new law, the State Mining Bureau now exercises supervision over the exploitation of the oilfields in California and will be in a position to remedy certain notorious abuses, especially the infiltration of water into productive wells. The State Mineralogist, Mr. Fletcher McN. Hamilton, has appointed Mr. R. P. McLaughlin as Oil and Gas Supervisor to carry out the provisions of the law. He will select four deputies to collect the necessary engineering data. However, the activities of these officials will be in the direction of instructing and aiding the operators rather than in subjecting them to irritating inquisition. We believe that all concerned will co-operate to the useful purpose designed by legislation and trust that it may prove a beneficial example of State supervision.

WE have been asked to discuss Mr. J. R. Finlay's interesting remarks, in the latest bulletin of the Mining and Metallurgical Society, on industrial energy as a military weapon, in which he says practically that a nation's greatness is measured in tons of pig-iron. Apart from the fact that we still consider human life to be guided and modified by the great imponderables, we deem it unwise to discuss problems so closely connected with the War and the natural prejudices arising therefrom. Most of our readers like to think that in picking up this journal they will derive information on matters outside the pervading horror of organized calamity.

ALREADY names are being mentioned for the directorship of the Bureau of Mines; that of Mr. H. Foster Bain has been mentioned for the office and steps were about to be taken to promote his candidacy. His many friends will be interested to learn that we sounded him on the matter and have received a reply, by cablegram, that he is not a candidate but desires earnestly to support Mr. Van H. Manning for the appointment. Mr. Manning was the loyal friend and assistant of the late Director, Joseph A. Holmes, and is now the Acting Director of the Bureau. We have every reason to believe that he would prove a fitting successor.

WE NOTE that the Canadian Mining Institute is discussing the granting of a medal in recognition of acts of bravery by workmen in and around mines and smelters. There is no question but that such medals are often deserved, for there is no braver man than the miner; the risks of his occupation make him fearless almost to recklessness. And in the discussion with regard to the granting of this medal the principal objection was that the knowledge of the offer of such a medal might make miners even more reckless. There is undoubtedly some force in this objection, for the desire to be thought a hero leads men to run needless risks; indeed, the record of mining accidents shows that more than three-fourths are due to some one's carelessness. Hence anything that tends to increase recklessness and carelessness should be avoided. On the whole we believe that the miner's contempt for danger needs to be repressed rather than encouraged and that the giving of such medals is likely to work contrary to the Safety

First principle. There is no reason, however, why brave deeds may not be rewarded in such other ways as seem just and expedient.

THRIFT is becoming fashionable, partly by precept but chiefly by force of hard times. Professional men are not remarkable as exponents of the Samuel Smiles idea, for their methods of life conduce to an open-handedness that rejects petty restrictions. In one direction at least they cannot afford to be niggardly, and that is in the acquirement of information. While thrift may lead a man rightly to avoid $5 dinners and to eat at a cafeteria, it ought not to shut-off his mental pabulum. In fact, when times are hard, and theatres and dances are too expensive for the lean purse, the time and money that are saved perforce may well be spent in buying books and in reading, preparatory for the days of activity ahead.

IN the latest bulletin of the Mining and Metallurgical Society of America we were glad to find an account of the testimonial dinner to Mr. Henry S. Munroe, on his retirement from the professorship of mining in Columbia University. The various speakers laid their wreaths of laurel at his feet with a grace befitting the occasion and the man they were honoring, yet, not unnaturally, we found the Professor's valedictory the most interesting of the speeches. At such times an earnest man is apt to tell not only the truth but the particular truths that he thinks may best further the cause in which his life has been spent. To his own students the speech must have been deeply interesting and touching in its good sense and sincerity. "In a school for the training of engineers—the men who do things—the instruction must be practical." "A mining engineer must first be an engineer." "His training must be broad and fundamental." These were salient points. In concluding, he spoke of instruction by lectures, indicating the weak and the strong features of this method of education. We commend his remarks to teachers of mining and metallurgy, for they embody 38 years of experience in a school of mines that has proved by its graduates that its methods cannot be far wrong. We join with the Columbia men in recognizing Professor Munroe's services to the profession and in wishing him many more years of health, happiness, and useful work.

Signs of Danger

With the extension of mining activity and the awakening of speculative interest there come divers printed invitations to buy stock in mining companies. We have two before us. One begins by quoting some extensive generalizations out of a Government report and then adds some warm commendations proposed by a 'professor' on the company's board of directors. The lack of quotation marks, particularly at the point dividing the official from the unofficial report, is a danger sign to a wide-awake speculator. It is a red flag. Next we find a photograph of a trench, so many of which now disfigure the face of the earth. This is described as a "shaft" in which the "ledge" was "tapped" at 32 feet. The assay of the ore is given as 49½% copper, 4.96% gold, and 1.17% silver. A rough calculation will prove that every ton must contain 1123 pounds of merchantable metals, worth over $30,000. Some mine that! Did the lucky discoverer proceed to take it out with his candlestick, his knife, or any other rudimentary tool? No; the shaft was "abandoned on account of the immense amount of water encountered therein." Yet it was on the top of a mountain. The story lacks verisimilitude. Let us dismiss it as unconvincing. Another mine, in Colorado, not in California, as was the last, is reported to consist of a large number of acres. Probably it does. It has a "true fissure vein." That is early Victorian; we have outgrown it. Average assays during the development period show $152.52 per ton "on this vein," which is 5 feet wide. That looks attractive. Besides two tunnels, the company owns "a flat formation" and "a titanium vein running the full length of the property." What is to hinder? The existence of two tunnels is explained by the necessity for fresh air; but this phase of mining requires air heated to a temperature capable of inflating a balloon. In the concluding paragraph it is asserted that the mine has "ore that cannot be all taken out for several years to come." We move to delete "all," in order to insure accuracy of statement. The stock is to be guaranteed by a redemption company at Rochester, N. Y., "as to principle, together with the endorsement of a large trust company." To endorse such principles not a trust company but the Y. M. C. A. or the W. C. T. U. ought to be engaged under heavy retainer.

Publicity and Advertising

Sweet are the uses of publicity, to those that understand them. Not long ago we received a call from a gentleman who had a grievance against a company that had obtained control of some mining claims formerly belonging to him, and had then done things that did not suit him. Whereupon he and a friend of his had prepared an article that we were invited to publish. It contained an *ex parte* statement of the case and was intended to hold the company up to public opprobrium. We told him that we could not lend any of our reading pages for the purpose of a private quarrel, and that if he wanted to publish a statement of his point of view, he could obtain the use of the necessary number of pages in our advertising supplement at the usual price per page, provided his statements were not libellous. Whereupon he said that he could send the 'story' to an Eastern non-technical magazine and get paid for it. "Yes," we retorted, "and have it treated as fiction." Of course, if he wanted publicity, we added, he ought to pay for it like a man and not expect to smuggle a partisan version of a business tangle into the reading pages of a paper. The incident is suggestive. Undoubtedly if a person wishes to make a statement to the public—in this case to the members of the profession and to the special public interested in mining—he should pay for the neces-

sary space on the advertising pages. Then the reader, seeing it, gives it at least the respectful attention due to a man who has paid money in order to get a hearing. There is no disguise. The reader is not irritated by going through an article that has editorial endorsement to the extent of being presented as a fair statement of a controversial matter, only to find when he has finished reading it that an attempt is being made to excite his prejudice. As a matter of fact, people often waste a lot of time and trouble in these devious ways when a direct appeal by advertisement would be vastly more effective. Suppose this man had taken four pages to tell his story in the advertising section, surely the mere fact of doing it in this straightforward way would have created a presumption of his good faith; undoubtedly his complaint would have been read with keen interest, and he would have obtained exactly what he wanted: publicity. Mr. Thomas Lawson, irresponsible and untrustworthy as he was in his self-imposed duty of advising the public, was clever enough to know this. When he wanted to catch the public eye, in order to give it one of his flamboyant messages, he did not waste time in suborning editors or in bribing publishers. He simply bought a page or more, according to his requirements, and told his story on it. The average man saw for himself that Mr. Lawson had paid the entrance fee to talk to him; having done so, the frenzied financier was entitled to a polite hearing. He got it, most effectually.

Another case within our recent experience is that of a man who had devised a machine, of which he, being the inventor, thought highly. He sent a contribution to 'Discussion,' under cover of which he advocated the use of his machine and expatiated on its merits. We told him that he would not deceive anybody, that his fond statements concerning the child of his brain were only interesting to the family, and that if he desired to interest the profession in his mechanical device, he had better buy an advertising page and tell his story in a businesslike way. He had not the money to manufacture the machine, which had only been tried once under his own personal directions; he did not like to put it into the hands of an established manufacturer—which seemed the most obvious thing to do—but he hoped to interest somebody either to finance him or to give him an order for a machine. Under these circumstances the best thing he could do was to invite participation or support by explaining the principle of his device and telling the plain truth to those likely to take an interest in the matter. He is still thinking over our suggestion.

Not long ago we received a description, by a writer not known to us, of a tool used in mining. It was a tool for supplementing the use of certain machines made by a well-known manufacturer and it referred to this manufacturer's products only. Like Sir Boyle Roche, we smelled a rat, we saw it floating in the air, and we nipped it in the bud. It looked like a write-up. An illustration, accompanying the text, had the appearance of being cut out of a catalogue. The description had been sent with a request for payment "at the usual rate." We replied that it was not suitable for publication as an independent article but that we would be glad to publish it, being interesting, under the heading of information "furnished by manufacturers." Our correspondent replied protesting that it was written on his own initiative and not in the interest of the manufacturer so plainly indicated. We returned the manuscript, but shortly after received a letter saying that the writer was in the employ of the manufacturer and would agree to the placing of the article as we had stipulated. As a matter of fact, the same information on an advertising page would have been more widely read and would have been more convincing. The average reader becomes irritated when he finds that an article purporting to be an unbiased technical description is really an ill-concealed advertisement. The reader expects the editor of a reputable paper to protect him against advertising that masquerades under the guise of detached technology; he loses his confidence in all reading matter when he detects the fact that some of it is being used to obtain commercial publicity under the guise of a scientific description. The engineer, who is our most honored reader, likes the reading matter and the advertising kept separate, to the gain of both; when they become confused, he cares for neither. When the reading page is misused, the advertising page is ignored. The advertiser who invades the reading page depreciates his own advertisement. The advertising pages of a paper are effective when the reading pages have won the complete confidence of those who are possible purchasers of the things advertised.

Should Directors Speculate?

This question was put recently by the New York *Annalist* to a number of men prominent in financial and corporation affairs. The replies are highly interesting as giving the public a trustworthy consensus of opinion on the part of those into whose hands the administration of corporate enterprise is consigned. Our readers will agree that in these matters it is well that there should be a clear understanding.

In the investigation mentioned, it was ascertained that "all but a few" of the directors considered that they had "a right" to use the information coming to them in their official capacity, that is, to use it for the purpose of their own profit. They were in general agreement that "a director is not a trustee for the rest of the stockholders," so that he is "free to convert his inside information into market profit, if he can." Indeed, the fact that such trading on inside information may prove to be unprofitable is suggested as some sort of justification, on the basis that the taking of risk absolves a director from the charge of taking an undue advantage. One of the replies may be taken as typical:

"If we were all Christian gentlemen with a very fine sense of honor, I suppose no director would buy or sell stocks in his own company on information which comes to him as a director. As a practical matter nearly all directors do. If a director was a trustee, it would be a

different matter, but as far as I see, he is not that. He is an administrator on behalf of himself and of other stockholders, but he does not surrender his individual freedom when he becomes a director. If it were held that a man's holdings of a stock should be frozen up the moment he becomes a director, he being put under obligation neither to add to them nor to reduce them, I fancy very few could be induced to become directors." This statement has the merit of frankness. In his further reply, the non-Christian gentleman with no excessive sense of honor, but for all that probably a more trustworthy man than many who make loud protestations, states that while it might be "rather raw" for a director to sell stock on fore-knowledge that a dividend was about to be passed, yet he would be "within his rights." This 'right' to make money on the side, and by use of confidential information, is excused on the further ground that the director's fees afford no adequate compensation for the time and trouble consumed in the management of corporate affairs. Therefore, the director is entitled to make use of the advantage that accrues to him from priority of information. But this witness is frank enough to conclude by saying that "it might be better if directors were paid a sum commensurate with their service and were then barred from dealing in their own stock, but as a practical matter it is not so."

Here we have the case stated plainly. While no particular reference is made to mining companies, it is obvious that the argument affects them particularly on account of the fact that discoveries of rich ore and the other recognized vicissitudes of mining afford unusual opportunities for using inside information to gamble in shares.

The subject is as old as the joint-stock method of operating industrial enterprise. The mere fact that the question can be put to responsible men suggests a growing opinion that speculation by directors is wrong. To that extent the discussion is an excellent sign. Nobody asks whether a director is free to go to the cash-box and help himself; nobody wants to know whether it is proper for a man to sell short on his partner; nobody raises the point as to the propriety of a trustee using his trust for private gain. We have settled those doubtful points long ago.

In discussions of this kind it is essential to start with a definition of the principal terms used. An attempt to define the terms employed often goes far to answering the question at issue. A 'director' is one that directs; he is also one that superintends or manages. To 'speculate' is to take the risk of loss in view of possible gain; it is to apply money upon an uncertainty in the hope of profit; it is to bet on one's judgment in the expectation of making a killing. If a director be one that superintends and manages his own personal affairs only then his actions do not concern the present inquiry. Obviously he is one that manages the affairs of others. Therefore he is in a fiduciary position. We do not accept the denial of trusteeship; that is implicit in a position involving the use of other people's money. If he speculates in the true meaning of the word, which involves risk, he is not doing what is most objectionable. The underlying objection is to a gentleman betting on a certainty. When he has information to which others equally entitled will obtain access after he has bought or sold shares, he does not 'speculate,' he steals a march on them. As the non-Christian and not too sensitive witness for the defense said, in regard to acting on fore-knowledge of a dividend, it is "rather raw." In short, our view has always been that directors are trustees, not privileged speculators; they represent all the shareholders, not themselves or their group of friends only; we maintain that the shareholders as a whole are the owners of the mine and that the directors are merely officers elected to protect the interests of those shareholders—all of them.

As to the meagreness of their emolument as directors, this is a pitiful excuse. A man's honor is not supposed to vary with his salary. And though it is evidently impossible to pay a dishonest man enough to keep him from cheating, which is really what acting on advance information means, yet if shareholders expect the wholehearted service of their company-officers they should pay them for their time and trouble. In London, where joint-stock finance has been so largely developed, it has become the custom to pay, not a mere fee, but a salary of £100 to £200 per annum, with double the amount to the chairman. Of course, in the more important enterprises the pay is bigger. The fee of a guinea per meeting only lingers now in the nickname of 'guinea-pig,' given to those who appear to go on the boards of companies in order to get pocket-money. As a rule, the type of man trained in company affairs and in a particular business will be a director on several boards, so that he may be in receipt of a considerable income from this particular source. In any case, inadequacy of remuneration cannot be given as an excuse for share-dealings on the side. In this country the fee of $5 or $10 for attending the relatively infrequent meetings of a mining-company directorate is a belated anachronism. Directors ought to be paid for their time by the shareholders for whom they ought to be working. And when the existing custom is changed, we hope that the British mistake of having large boards—of 7 or 9 directors—will be avoided. In the end a board is likely to be dominated by one man, with the others to advise or to divide the responsibility. The ideal administration should consist of a managing director with two assistants, and at their meetings the consulting engineer should be present *ex officio*. However, to return to our immediate subject, it is obvious that whether a man be paid $20 or $2000 per annum for his services as a manager of the affairs of his fellow-shareholders, it does not discount his obligation to not take advantage of a place of trust. If the method of raising capital for mining ventures by issuing shares to the public is to be placed on a sound basis, it is imperative that the status of a director should be properly defined. This can be done, not by legislation, but by crystallizing public opinion on the subject, by discussions such as that started by *The Annalist*. We shall return to the matter in a later issue.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Mining Claims in National Forests

The Editor:

Sir—That Mr. Barrett understands the intent of Congress is evident when he says: "Congress recognized that in establishing National Forests covering the main mountain ranges of the West—for the purpose of conserving water and growing timber, etc." That is exactly what Congress intended, and in making the Forest Reserve cover the watersheds it would, of course, be unavoidable in places to take in mineral land, and in order to protect a watershed it might be necessary to include agricultural land and plant it with trees. What Forest Reserve people overlook is that it was the intent of Congress to protect the watersheds and do nothing else. Does Mr. Barrett claim that Congress authorized the making of a Forest Reserve out of the sagebrush deserts or is it forbidden by the section of the statute I quoted. It is hardly necessary to point out that water-power sites are always in the valleys of streams, while the lawful home of the Forest Reserve is on the top of the mountain. It is only necessary to refer to the bulletins issued by the Forest Service to prove that most of its activities have nothing to do with the protection of the watersheds. There is not a word in the statute that can be construed to authorize the employment of veterinary surgeons to care for the disease of livestock or of mining experts to report on mining properties. It would take up too much of your space to quote from Forest Service bulletins and other official records to prove that these charges of usurpation are not baseless. Bearing in mind the old maxim "*falsus in uno, falsus in omnibus*," let us consider the case of the Forest Reserve covering the mudflats on the shore of Controller bay in Alaska and admit if you will that President Roosevelt established this Reserve in a fit of absence of mind without considering the absurdity of making a Forest Reserve out of tide-lands. When President Taft restored a portion of these flats to the public domain, the Forest Service, led by Mr. Pinchot, made a bitter and venomous attack on him. Will Mr. Barrett explain why this attack was made on Mr. Taft for doing his duty, unless the charge is true that the Forest Service wanted these flats for some purpose besides the raising of trees and conservation of water? The principal object of a discussion of this kind is to call attention to the importance of obeying both the spirit and the letter of the law. The law authorizing the establishment of Forest Reserves was sufficient if any attempt had been made to carry out the plain intent of Congress. It was beyond question the interest of Congress to establish Forest Reserves to protect the watersheds of our streams, and for no other purpose. Care should have been taken to establish the boundaries of these reserves so that they would be perpetual. If these reserves are needed now the necessity will increase as the years go by. They should be in charge of expert foresters, who should devote their time to the care of trees. The control of livestock ranges, the regulation of coal mines and water-power sites, and the care of forests outside the Forest Reserves are matters to be entrusted to the Secretary of the Interior, and the rights that citizens have on the public domain should be defined by law. It is only necessary to read the Forest Reserve use-book to see that the rights of citizens on a large part of the public domain depend upon the will of the forester and a permit granted today can be revoked tomorrow. What Western people ask is regulation by law.

Salt Lake City, August 4.

Do Engineers Talk Enough?

The Editor:

Sir—The men who make the most money in mining, as in general business, are those who talk. The rarest quality in the systematized conduct of industry is the ability to talk well when there is opportunity. New ventures are undertaken, and businesses built up, enlarged, or made more profitable, by someone who expresses his ideas in words that convince.

An engineer tends toward paucity of speech, toward brief utterances, and toward consistency. Frequently the man who is employing him gets out of patience with his pedantic narrowness of view; very likely the employer made his money by his failure to be consistent, by his visions, his accomplishing 'after a fashion' things that engineers said "cannot be done." The conversations of financiers, men of affairs and directors smack of inconsistencies, irrelevancies, dilution, and changes of purpose.

The men who hire engineers (and in whose positions engineers long to be) have the courage and the initiative to start a new business, prospect, or phase of things; to see it sink into failure; and then to find a way out. They can forget an original collapse of their hopes, and out of the muddle of their first purpose, build a side issue that is as good, or better, than the results they had tried for. Through all the trials, changes, and inconsistencies, they must talk, and think aloud, say things they don't mean for the sake of hearing how they sound, converse with

associates to get new ideas and suggestions. And here is where the typical engineer falls down. He lacks the ability to talk; he is pessimistic, dumb, and suggestionless; he is frightened by glaring contradictions to what he had learned; he is barren of constructive ideas unless they be along lines with which he has been accustomed.

The most able men in business are those who understand how to handle and draw out other men in the same business, their superiors in position as well as their inferiors; those men who know conditions; who can recognize ability mixed with inability, who convince others that *their* way is the way things get done. A man's associates in business are part of his stock-in-trade; they make it possible for him to achieve his plans, to reach other men, and to carry his point. And the quality and quantity of one's associates are determined largely by one's ability to talk.

The average engineer does not appreciate that in this country, and in this particular trend of the world's affairs, there is an immense amount of dilution in business —and in talk. Long conversations take place in New York, Boston, London, on trains and steamers, underground and in the hills, which would assay only about one-tenth of 1% in importance; the balance being preliminary, irrelevant, inconsistent, bluff, hope, fear, feeling-the-way, and filling in. But it is all more or less necessary, because it is the way things get accomplished in these days of loose aggregations of business units and of ramified finance.

An engineer, when he gets around to say something, usually means exactly what he says. That makes him a good engineer, after a fashion. But if he aspires to bigger game, to doing things for himself, or to being a part of big affairs, he learns to talk more. He finds out that, unlike engineers, other men (including the 'big men' of finance, and their associates) say many things that they don't mean. Some things they say because they wish they were so, others are highly colored exaggerations uttered for the purpose of cheering themselves up, still others are underestimated little details that nearly everyone knows are due to this reason or that, and must be allowed for. In other words, to accomplish big things, one must expect many inconsistencies, much that 'shouldn't be so' but 'is,' numerous peculiarities, exceptions, and disproportions, and through it all, talking is necessary, to fill in, to satisfy, to lead on, to give suggestions, and to create.

Does the engineer talk enough? Perhaps he does for an engineer. But these are hard times for engineers who can only engineer. An engineer who talks enough for an engineer, may not talk enough for his own best good. Few engineers care so much for engineering, simple and unadulterated, that they wouldn't mix it with something more profitable. The answer is, learn to talk.

Not necessarily is a good talker one who talks a lot. But it is better to talk a lot, say a little worth while, and interest somebody, than to say nothing at all. Great matters spring from trivial remarks, and a chance conversation may be the means of important developments. On the other hand, one should not become a bore. A good talker, rather than one who talks a lot, is one who has a respect for talk, who listens well, puts in a reasonably practical remark, and who makes allowances for talk that is only talk.

Important talks, concerning good-sized issues, are difficult matters to plan in advance, and rarely do they come about just as planned. There is always the other man to be considered, with his personal ideas, feelings, prejudices, and general health, all having a bearing on the interview. Still, while it is useless to plan out one's line of talk in advance for any particular interview, it is well to have in mind a clear idea of the points of the case, carefully threshed out. After one has heard the other party to the meeting utter his first few words, he can decide on what tack to approach him and work in the particular points he wishes to bring out.

Men get important positions, commissions, and privileges, because they are believed in and trusted by those in power. They get believed in because they have talked and made an impression; they said things that appealed to somebody; they struck a point of view that supplied what was lacking. They were convincing, sincere, plausible; and it looked as though what they said was right. A successful man may know much less about his own business than one of his under-paid engineers, but he talked and made the business. It is his business. If an engineer can talk, he stands a chance of being able to sell his talking for more than his engineering. That is, the talking will greatly enhance the engineering. Everyone is susceptible to the right kind of talk, even captains of industry and capitalists who care little for engineering.

Of course there are times when "silence is golden," and much is gained by knowing when to keep still. But a man should say something once in a while, and he should make himself interesting when he talks, and not confine himself to technical utterances, and 'knocking.' He can undoubtedly 'hold his job' by keeping still and saying nothing, but he'll be further ahead in ten years, and will have lived more, by cultivating the knack of talking, so that when the opportunity presents he can direct the conversation and impress his personality and abilities on someone whom he desires to impress, rather than keeping still and thinking what he'd like to say if he dared. A man who can talk and 'put a thing through,' who gets listened to with attention, who can interest and convince his hearers, will get along. A good talker needn't be an orator, nor a liar, nor a bluffer, but he should know how to attract attention to himself when he sees that he can gain something worth while by doing so. Talking that convinces, that sounds like 'the way out,' that clears matters up, is valuable. 'Tis a great thing, talking; we all fall for it.

P. B. McDonald.

Gouverneur, N. Y., August 2.

Operating units should be worked to full capacity. A zinc-lead mine in southwest Missouri formerly hoisted 2,300,000 tons of ore through 24 shafts. By changes in the transportation system 13 of the shafts were abandoned and a yearly saving made of $1,000,000.

Platinum Assaying at the Boss Mine

By FRANK A. CRAMPTON

Upon assuming my duties as assistant superintendent at the Boss mine, Goodsprings, Nevada, it became apparent at once that some assaying method must be devised rapid enough to test the daily samples and yet secure a commercial degree of accuracy. When it is understood that the assay for gold, copper, platinum, palladium, and at times silver, in the same sample must be completed in time for the next lot (say of from ten to twenty samples) it at once becomes apparent to the assayer that methods involving less than two to four days must be devised. It will be interesting to follow the course pursued in eliminating the older methods and developing the new. Each of the standard methods had its strong points, but the vital factor of time made each out of the question for our purpose, especially as these methods required, in most cases, from three to five assay-tons, of which the fusion and cupelling alone would take nearly a day.

The first method used is the one chiefly in vogue on the Pacific Coast, the procedure being the same as with gold, only, instead of the smaller charge of a half or one assay-ton, 5 A. T. is required; an estimated amount of silver, equal to at least 12 times the amount of platinum, being added to the fusion. After cupelling, the button is parted in dilute HNO_3, then in concentrated HNO_3, leaving the gold as residue. The silver is precipitated with HCl, added drop by drop, the solution being then filtered twice and washed thoroughly. Silver-free zinc-dust is added in excess of any acid reaction, the solution filtered, the filter-paper dried and ignited, a known amount of silver added, and the whole then mixed with a proper flux and reduced to a lead button. Proof-silver is run alongside this, and in weighing the cupelled buttons the loss in silver is used as a correction on the Pt-Pd button. This method proved unreliable, as the zinc invariably precipitated some of the silver still in solution, resulting in silver being weighed as platinum-palladium.

Another method, described by J. Ohly, in his 'Analysis, Detection and Commerical Value of the Rare Metals,' on pp. 79-82, was used in combination, so as to include both platinum and palladium. This method, though accurate and by far the most satisfactory of any of those used, took more time than could be given, inasmuch as the treatment necessitated an additional step: not combining the two elements in one single operation but allowing the use of the same solution throughout. As copper in the ore interfered and complicated the assay, Ohly's method for eliminating this element (page 86) was used.

Ricketts & Miller, in 'Notes on Assaying,' pp. 130-135, give two methods for the determination of platinum. In the assaying at the Boss mine, palladium must also be determined. To do so by this method, a complicated series of steps is necessary, involving the method described by Ohly as well as the addition of formic acid. The method naturally took more than the available time, but for accuracy of results compared favorably with the others.

Furman, in 'A Manual of Practical Assaying,' pp. 310-311 and 246-249, gives the assay for gold bullion. This was modified with several additions in such a manner as to allow the assaying of ore to determine the palladium. The method is very clumsy, though as accurate as the others. Another method noted, but not used on account of its length, was recently described in the *Mining Journal* of New York. Other schemes, not worthy of mention on account of their unreliability, were tried and, though aiding, each in a small way, in devising the final method, cannot in themselves be termed worthy of note.

The method now in use, the one finally developed, makes use of the solution after parting platinum, palladium, and silver from the gold in an ordinary assay upon ½ to 1 A.T. of pulp, depending upon the content. In assaying hundreds of samples, the assayer is soon able readily to distinguish a low-grade from a high-grade ore. Silver, estimated at about 15 times the platinum-palladium content, is added to the crucible-charge. The fusion is made at a high heat throughout, and in cupelling the lead button a moderately high heat is maintained: a heat above that required to 'flower' being the more satisfactory. The button is parted first in ordinary dilute nitric acid, and when the parting is apparently complete, 5 c.c. of concentrated nitric acid is added and boiled 10 minutes. Then pour into a casserole; the residue (gold) is washed in a 1 to 10 solution of nitric acid and the washings added to the casserole; the assay for gold is then finished in the ordinary way.

At first the solution was taken up in HCl after evaporation, and the silver eliminated by filtering twice. This step, however, proved unsatisfactory, owing to there being some silver still in solution. This, when the platinum-palladium content is above 2 oz. per ton, has a tendency to precipitate with them. The discovery led to a development of the present method, after the use of HCl was discarded. The precipitation of the platinum-palladium is somewhat the same, without alcohol and without boiling prior to adding formic acid.

The present method, after parting the gold, takes less than three hours for 20 samples and is conducted as follows: The silver is precipitated by a super-saturated solution of sodium chloride, filtered first with a wash, then re-filtered without a wash. The filtrate is neutralized with ammonium-hydrate in slight excess and brought

to a boil. Formic acid is then added till the solution becomes distinctly acid, even strongly so, and boiled briskly for from 20 to 30 minutes. (If the platinum content is high, 10 to 15 c.c. alcohol is added after the formic acid. This is readily determined, as the parted solution shows strongly yellow if over ½-oz. per ton platinum-palladium is present.) After boiling, the solution is filtered without washing, the filter-paper dried, ignited, and the residue wrapped in lead-foil and cupelled, allowing the completely cupelled button to remain in the muffle about 10 minutes more and raising the heat. The resulting button is weighed and recorded as platinum-palladium, a further parting not being necessary for ordinary purposes. It is not necessary, but preferable, to ignite the filter-paper; this, however, can be omitted and the filter-paper wrapped in lead-foil and cupelled. The difference in results is very slight, but in favor of ignition first. The results of tests are given below:

Sample No.	1.	2.	3.	4.	5.
Filter ignited	0.63	0.18	0.32	0.07	2.42
Filter cupelled	0.61	0.18	0.31	0.07	2.38

the error being a little more than 1%.

When a silver determination is necessary, a known amount is added, the button weighed before parting; after the gold and platinum-palladium assay is complete, the silver content is readily computed by difference. It is well to run a proof at the same time for correction purposes.

The following table is inserted in order to compare the various results by the different methods. They were picked at random from a score of comparative assays, and for the three grades of ore. These results are averaged from three assays each on each method employed and on the same pulps:

	High grade.		Medium grade.		Low grade.	
Method.	Au, oz.	Pt-Pd, oz.	Au, oz.	Pt-Pd, oz.	Au, oz.	Pt-Pd, oz.
J. Ohly	79.62	246.12	1.53	0.67	0.18	0.22
Zinc-dust	81.33	272.48	1.51	0.84	0.18	0.31
Ricketts No. 1	80.86	233.19	1.53	0.51	0.18	0.16
Ricketts No. 2	84.37	239.63	1.53	0.54	0.17	0.19
Furman	82.66	249.37	1.52	0.65	0.18	0.20
New (no alcohol)	81.99	245.83	1.53	0.67	0.18	0.20
New (alcohol)	82.87	247.21	1.53	0.69	0.18	0.21

It is probable that the lower platinum-palladium results by the Ricketts & Miller method are due to the incomplete precipitation of palladium, while the high assay by the zinc-dust method is due, of course, to silver being weighed with the button, having been precipitated by the zinc. Otherwise, the table speaks for itself.

It can be seen at a glance that the new method compares most favorably with the older ones. Inasmuch as the assay for gold was made on all the samples, it is inserted, though it has no distinct bearing on the platinum-palladium assay. Assays for comparison on the silver were not made, but it is reasonable to expect that the check would be as close as in any other silver assay.

Extreme accuracy is not claimed for the method, but merely an accuracy commensurate with the relative importance of daily samples for a mine in process of being developed. It is only fair, however, to say that 0.05 to 0.06 would be the extreme error per ounce of platinum-palladium, by this method.

It is a pertinent fact, and one worthy of note, that reports on samples of pulp first assayed at the mine and then sent to representative and reliable assayers would show a wide variation from each other, and a sample of the same pulp, submitted to one assayer was reported differently each time. This seems to be the rule rather than the exception, and naturally leads one to the conclusion that assayers either are not familiar enough with the determination of platinum or show a marked degree of carelessness. Possibly the methods employed are not the proper ones; at any rate there is something wrong. The following table, on the assay of six samples, is inserted for comparison:

Assayer.	1.	2.	3.	4.	5.	6.
Self	0.16	1.15	0.11	1.18	0.11	0.65
No. 1	0.32	...	...	...	0.08	0.76
No. 2	...	0.82	0.07	...	0.03	...
No. 3	...	...	0.32	3.57	...	0.48

The results, of course, are for platinum-palladium only. It is hard to tell which are correct and which are not; the wide variation would seem to indicate, however, that the proof of accuracy is yet a factor to be determined and that co-operation and the exchange of ores as well as of notes by the different assayers would be a step in the right direction. It would appear to me that the more numerous the steps in an assay, the greater the chance of error. The elimination, wherever possible, of all but the basic steps, lessens the chance of loss and gives results more uniform throughout. The following table of an assay on the same ore by two methods, both comparatively short, the shorter being the Boss method, shows the variation to be wide, even when conducted by the same assayer.

Ohly method.	Boss method.
1.61 –0.73	1.62 –0.69
1.64 –0.70	1.64 –0.71
1.62 –0.62	1.62 –0.66
1.62 –0.66	1.62 –0.69
Average 1.622–0.677	1.625–0.687

The averages here check as well as could be desired; however, an extreme variation of 0.11 oz. is noted by one method and 0.05 oz. by the other, a little too much for even commercial work on metals of which each 0.01 oz. is equal to 40 cents.

I do not claim any originality for the new method, and wish to give due credit to the aid afforded by older ones. The Pacific Platinum works uses, it is understood, a formic acid method similar to the one in use at the Boss mine, and it is primarily through study of that method that the present one was evolved.

COPPER AND SULPHUR DEPOSITS are reported to have been discovered in the Planchon pass, between the Colorado and Atuel rivers, province of Mendoza, Argentina. Their altitude is about 6500 ft., according to a consular report of June 12 from Rosario.

The Hydraulic Compression of Air

By A. E. CHODZKO*

It is interesting to the student of coördination of the development of industrial progress to note the features in its processes of evolution that are common to different lines, and in no division, perhaps, of that vast subject are they more conspicuous than in the generation and the utilization of motive power.

For instance, a jet of steam impinging upon vanes or buckets attached to the periphery of a wheel, or else issuing from a point of its rim, was the first concrete form of a steam-motor; it now represents the most advanced type of that class of machinery, after an interval of many centuries, although the far more intricate reciprocating engine was gradually developed in the meantime. The direct use of air under pressure for raising water, which in the light of modern familiarity with their practical combination, offers an efficient method of pumping, was distinctly outlined in the well known 'Fountain of Heron.' Nevertheless, this early suggestion remained unheeded until many elaborate designs of pumping machinery had gradually been evolved and perfected. The same is true of the compression of air. The crude and classical *trompe Catalane*, used for forge-blast in the small charcoal-iron factories of southern France, had long been relegated to the position of a mechanical curiosity, and been superseded by motor-operated fans.

As higher air-pressures were demanded, the piston machine was developed to a remarkable degree of excellence. It was followed, in course of time, by the high-pressure centrifugal, better adapted to large capacities. Continued progress in that direction has brought back a process primarily based on the principle of the ancient *trompe*, namely, the hydraulic compressor.

Two main features seem to characterize this gradual progress of human ingenuity; the first, of a general, not to say universal nature, is the tendency of advancing knowledge toward a return from the complex to the simple. In almost every industrial effort, the desired object is first attained by some intricate and cumbersome process or device. This is followed by a gradual blending of its useful elements into a smaller number. Later comes the weeding out of unnecessary intermediates between power and resistance. The second tendency, less general perhaps than the former, because it admits of of some exceptions, is the discarding of intermittent in favor of continuous motion. These exceptions are found in cases where great variation of speed or frequent reversals in the direction of motion are a necessity; they do not detract, however, from the logical and general character of that tendency.

The hydraulic compression of air is the subject of the present paper. This can hardly be termed a novel process, since, aside from the remote origin already indicated, the first patent covering its application on a large scale was taken out by Joseph P. Frizell in 1878. The following quotation from his treatise on 'Water Power' gives a comprehensive presentation of the principal features of that process.

"It is founded upon the familiar observation that water thrown into commotion breaks into foam, and becomes impregnated with minute air-bubbles, and upon the further fact that these bubbles rise through water with a very moderate velocity, and in a descending current, are carried downward and subjected to a pressure conformable to the depth. Fig. 1 shows the arrangement for applying these principles on a practical scale. It assumes a fall created by a dam on a running stream. It

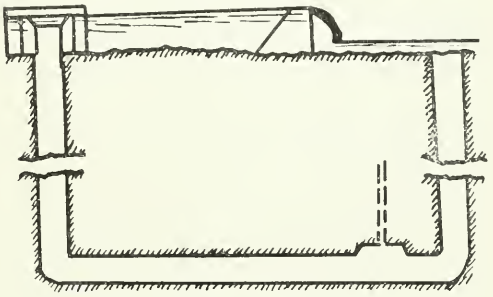

Fig. 1. SKETCH OF FRIZELL COMPRESSOR.

also assumes, what is generally the fact at a fall or rapid, a rock formation at no great depth. On the up-stream side of the dam, a vertical shaft descends into the ground to a depth corresponding to the required pressure. At that depth, its direction changes to horizontal, and it pursues this course to a point below the dam, where it joins a second vertical shaft opening into the river. Around the entrance to the shaft, a masonry structure rises to the elevation of the dam or something more, and is provided with means for controlling the influx. Over the horizontal passage, a capacious chamber is formed, provided with an impervious lining. The air-transmission pipe leads from this chamber. Water entering the descending shaft from different directions, meets with a high relative velocity, and is thrown into violent commotion which impregnates it with air-bubbles of a minute and very uniform size; such bubbles tend to rise with a velocity of no more than one foot per second, and the descending current being four feet or more, they are carried downward. In the horizontal part of the passage, the air is free to rise and accordingly enters the air-chamber, and there accumulates under a pressure corresponding to the depth of the surface of water in the chamber below the surface of the stream. The water divested of its burden of air pursues its course, and rising through the ascending shaft, joins the river.

*Consulting engineer, Phelan Bdg., San Francisco.

"The compression in this method takes place isothermally, and avoids one of the principal sources of loss in machine-compressors. The losses inherent in the method are:

1. The head expended in impregnating the water with air, which includes the head due to the initial velocity, a fall of one foot in entering the shaft, brings in the water from both sides with a velocity of eight feet per second, and these two currents meet with a relative velocity of sixteen feet per second, which creates a sufficient commotion.

2. A loss which may be called the 'slip' due to the velocity with which the bubbles tend to rise. It is obvious that the rise of the bubbles during the descent of the water is a lost motion, to be deducted from the efficiency of the system.

3. The head consumed by the friction in the channels.

"A committee of the Franklin Institute gave its attention to this method, and in a formal report, pronounced it identical with the ancient *trompe*. This statement is entirely incorrect, and reflects little credit upon that time-honored institution. The conclusive and indisputable criterion between the two methods is this: The *trompe* cannot produce a pressure equal to the working head, or closely approaching the same. The device under consideration can produce a pressure many times the working head."

Considering the device on its general lines, a certain volume of water in the intake is allowed to fall into a vertical shaft, entraining by suction and by adhesion some atmospheric air, and gradually compressing it. The falling water is then deflected through a horizontal passage, where it meets a collecting-chamber. At this point the air, through its buoyancy, separates from the water and is led by a pipe to any place where it is intended to use it. The water from which the air has been separated is again deflected up another vertical shaft leading to the tail-race.

In the complete device there is but one piece of machinery, namely, the controlling-device for the admission of air and water. This device is practically stationary. No attendance is necessary, and if the shafts and passages have been carefully built and secured against leakage or caving by erosion, there is no apparent reason for considering it other than a permanent structure unless, perhaps, in the case of unusually gritty water.

It may be noted that aside from the small amount of air that might remain in suspension in the escaping water, the latter reaches the tail-race in the same condition as to pressure as when it left the intake. The work performed is therefore due to the fall of a certain volume of water from a height equal to the difference in elevation between them. This quantity may be computed exactly.

Whatever intermediate process may take place in transit between these two terminals, the result is the production of a certain volume of compressed air, capable of yielding an amount of useful work that can likewise be correctly determined. The practical efficiency of the system is the ratio of these two quantities of work. In practice efficiencies have been obtained comparing favorably with the most elaborate air-compressing plants.

It will be seen that the air-pressure depends solely upon the depth of the return-shaft leading to the tail-race, and is therefore apparently independent of the head. This, however, is not strictly true. A higher working-head is necessary for an increased air-pressure.

The experimental results realized with the Frizell hydraulic compressor led Chas. H. Taylor of Montreal, Canada, to propose a modified form of that machine. A machine of this type was erected in 1896 at the Dominion Cotton Mills, Magog, Quebec.

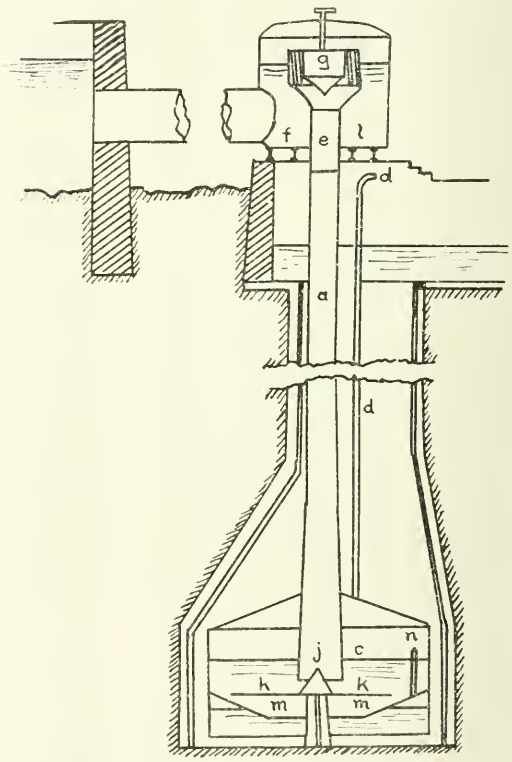

FIG. 2. SKETCH OF TAYLOR COMPRESSOR.

Fig. 2 is a sketch of the compressor used in that instance, taken, together with the following abridged description, from 'Compressed Air Plant,' by Robert Peele. "For the Magog Mills, a 128-ft. shaft was sunk to give the desired head and pressure: in it was erected a large vertical compressing-pipe *a*, 3 ft. $8\frac{1}{2}$ in. in diameter, the lower part gradually increasing to 4 ft. 8 in. and made of $\frac{5}{16}$ in. steel plate. This pipe passes through the bottom of a cylindrical intake *b*, 12 feet in diameter by 12 ft. high, connected to the supply flume. The pipe extends to a point a few feet above the bottom of the shaft, passing through the top of a cylindrical bell *c*, 17 feet in diameter and 12 feet high. This bell, entirely similar to those used for the storage of illuminating gas,

is open at its lower end, and supported about 18 inches above the bottom of the shaft, the top of which opens into the tail-race. The bell is entirely immersed in the return-water. Immediately under the open lower end of the pipe, *a*, a deflecting cone *j*, attached to a horizontal circular baffle-plate *k*, about 14 ft. in diameter, is secured at the centre of bell *c*. A pipe *d*, attached to the top of that bell, leads the compressed air to any place intended for its use. Returning to the top of the pipe, *a* in the intake, one finds a telescopic section *e*, riveted to a bell-mouth *f*. Immediately above this is a cylindrical head-piece *g*, open at its top and terminating below in an inverted conoid that penetrates the bell-mouth *f*. The head-piece is suspended to a central screw, by means of which it may be raised or lowered at will. This regulates the size of the circular inlet of water into the pipe *a*. The head-piece carries on its periphery thirty 2-in. iron pipes 4 ft. long, open at the top, which projects above the water-level in the intake. Into each of these and close to its lower end, are screwed thirty-two short horizontal ¾-in. pipes directed into the annular inlet-opening.

As the inrushing water passes among the small pipes, it tends to create a vacuum. Atmospheric pressure drives the air through the pipes in the form of small bubbles entrained by the water. With the water, they are carried down pipe *a*, their pressure increasing with the depth below the surface. As this emulsion of air and water issues from the pipe, it impinges against the baffle-shield *jk*. Its flow is abruptly swerved radially and at right angles, while the area of the stream is considerably increased. Its velocity decreases accordingly, and the bubbles, rising to the surface, are collected into the receiver formed by the upper portion of the bell *c*. The water, having lost most of the entrained air, is deflected by an apron *m*, toward the centre of the bell, and continues on its way to the tail-race. In so doing it follows the slanting outer face of the apron *m*. The remaining air collects at its connection with the plate *k*, and is led by the pipe *n*, to the receiver, and thence, through the pipe *d*, to the place of use.

The minute subdivision of the air increases its surface of contact with the cooling water to a great extent. The compression has been found to be actually isothermal. In a series of tests made by C. H. McLeod of McGill University in August 1896, the best efficiency in the Magog plant was found to be 62.4% with an effective air-pressure of 52 lb. gauge. This was realized with a delivery of 4005 cu. ft. of water, entraining 1095 cu. ft. of free air, per minute, the available head being 22.3 feet. Subsequent experience with this system has shown that the parts were not correctly proportioned in that first installation, and greater efficiencies have been realized in more recent application."

The same source of information mentions a plant built for the Kootenay Air Supply Co. at Ainsworth, British Columbia. The first portion of the induction pipe *a*, Fig. 2, which is 33 in. in diameter, is carried on a wooden tower 110 ft. high, whose base is at the level of the tail-race, and continued by a vertical shaft 105 ft. deep, the effective compressing-head being 107 ft. The main pipe-line 9 in. in diameter, is two miles long. It discharges from 4200 to 4600 cu. ft. of free air per minute, producing 600 hp. after compression. The volume of water and the efficiency are not mentioned. Owing to improved constructive features, the latter must have reached, if not exceeded 70%.

Another large plant was built in 1906 at the Victoria Copper Mine, Ontonagon Co., Michigan, containing three units in all. In one of them, with a working head of 70 ft., 14,820 cu. ft. of water was used to deliver 11,930 cu. ft. per minute at 114 lb. gauge-pressure, corresponding to 1623 hp. and an efficiency of 82.27%. It is expected that the three units will deliver 4000 hp. in all. The single unit at present in use operates, among other machines, a 500 hp. hoist designed for 4000 ft. beside seven pumps. The cost per horse-power per year is $2.25, including all operating expenses.

Other recent installations are, two in Germany and one on the Shetucket river, near Norwich, Connecticut. The latter plant was described in 'Compressed Air,' in April 1906. An underground plant developing about 60 hp. has been constructed in the silver mines of Clausthal, Bohemia.

The most important point of difference between the Taylor and the Frizell designs lies in the process adopted to induce the entrainment of air at the intake. The former uses a large number of small inlet-pipes, 1800 being used at the Victoria Mine. That is, it carries the preliminary subdivision of the air intended for compression as far as possible, apparently with the idea of increasing the cooling-surface. In the Frizell compressor, the head-piece consists of a funnel, in the shape of a square truncated pyramid, with its apex downward, attached to a telescopic piece of pipe. The following excerpt is from Frizell's 'Water Power.'

"Fig. 1 shows a telescopic pipe entering the descending shaft, carrying a hopper-shaped mouthpiece, which we will call the 'hopper,' and adjustable vertically by mechanism not shown. The hopper is guided in its vertical movement by four piers or guides. These form four channels of approach, through which four currents of water enter the hopper, and in meeting cause the necessary commotion. It was clearly shown by the writer's experiments at Minneapolis, in 1880, that throwing the water in commotion is an effective mode of impregnating it with air.

"Any arrangement of pipes for this purpose appears to the writer entirely superfluous as well as objectionable. The pipes could not fail at times to become clogged with floating debris to the extent of wholly arresting the flow of air. In the arrangement of Fig. 1, trash of every kind, blocks of ice, and even logs could go through the system without embarrassment or interruption, not even a rack being required. In this disposition, the position of the hopper determines the quantity of water drawn. The quantity of air regulates itself, and is neither more nor less than the given quantity of water can carry. If the descending column is so loaded with air that it does not preponderate sufficiently against the ascending column,

the water in the former will rise, the commotion will diminish, and less air will enter. In the contrary case, the water falls, commotion increases, and more air is taken in."

In the presence of two different designs, both evolved by persons of evident technical qualifications, and both founded on actual experience, a third party not possessing the latter advantage, can offer no comment other than remarks suggested by the records.

As the tops of the air-inducing pipes in the Taylor compressor stand above the water-level in the intake, their obstruction by floating debris seems probable. At the same time, an examination of the Frizell design suggests the possibility at least of blocks of ice or floating logs lodging in the air-chamber, whence their removal would be impossible without shutting off the water, and pumping out the underground portions of the plant.

Leaving aside the obvious superior simplicity of the hopper, and considering only the relative effectiveness of the two designs, the following foot-note from 'Compressed Air Plant' by R. Peele deserves insertion.

"Since the Victoria plant was put in operation, trouble has been experienced by the freezing up of the small pipes of the intake-heads, due to the severe winter climate of the region. This has led to the removal of the heads, as originally designed, the water being allowed simply to flow into the top of the compressing pipes. I am informed that the capacity of the plant, in cubic feet of free air compressed per minute, is practically the same as when the intake heads were in use."

This seems to show that the particular arrangement of the air-intake has no controlling influence on the practical efficiency of the plant. But the statement emphasizes, in a still more decisive manner, the simplicity of that system of air-compression. It may certainly be contended that in mountainous regions, compressed air may often be produced at a moderate cost of first installation and that the operating expenses would be, in not a few cases, practically negligible.

A self-suggested objection lies in the cost of sinking a shaft of sufficient depth to secure a convenient air-pressure, as such a shaft must be of substantial construction to insure permanency. This objection would doubtless be well founded in some instances; yet it might frequently be overcome by having all the parts of the plant laid upon or built at the surface.

Fig. 3 illustrates the case of a ditch or flume running along the slope of a mountain. This is dammed at A and the water is led by the pipe AB to the air-receiver B. This might be built above ground of reinforced concrete, or else, be excavated, lagged and cemented to make it air-tight. The use of pressure-tunnels in hydro-electric plants shows that such construction may be both inexpensive and substantial. The water returns through another pipe BE to a point E located at the proper vertical distance below A to secure the desired power. The same water is then returned to the ditch at F, the section of the tail-race EF being, of course, larger than of AF. All of the water is available for other uses below the position of the compressor. The portion AF might be omitted altogether and replaced by a short diversion-canal AE, to be used if it is desired to dispense with the compressor.

Similar plants could be established along a stream, either for operating machine-drills in a mine or tunnel, for pumping water to a point above the level of the ditch, or for still other purposes. Their design would obviously be governed by local conditions. For instance, the topography might not permit the extension of the pressure-pipes far enough downward for raising the air to a sufficient working-pressure. In such a case, the air might be delivered at a lower pressure, and conveyed to a piston-compressor, the hydraulic portion of the plant acting as the first stage in compound work, and permitting the use of a smaller machine to complete the compression.

In the case of a certain California mine, the total available head was such that the water-wheels operating the

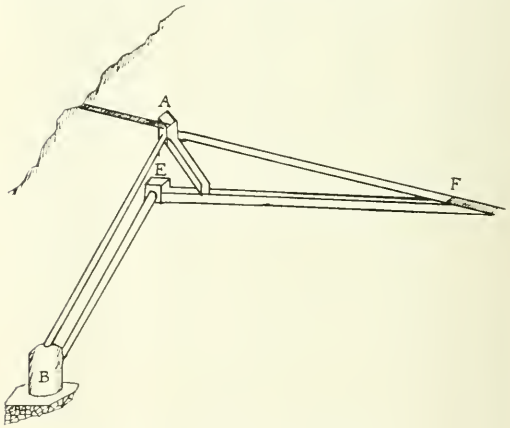

Fig. 3. Sketch of typical hillside plant.

hoist and the air-compressors are about 130 ft. above the river. Under these conditions, the tail-water of the wheels, which was going to waste, at a moderate cost could have been utilized to develop a considerable amount of compressed air. This air could have been used either to dispense with one half of the duplex machine in use at the shaft, or to operate an air-lift pump. As it was the pump frequently required so much air as to reduce materially the amount available for the machine-drills.

Like other processes apparently simple in principle, the hydraulic-compressor requires careful study in its practical design, in order to attain efficiency in the coördination of the various parts. The detailed treatment of a concrete case would, perhaps, prove a rather arid peroration to this paper, but its general lines may briefly be presented. The action of this machine is based upon the downward motion of a column formed of a mixture of air and water, against the back pressure of an ascending column of water alone. It may, therefore, be considered as the counterpart of an air-lift, inasmuch as the excess in weight of the descending column over the back pressure must be sufficient to cause the entrainment of

the proper amount of air, and to overcome the other elements of resistance.

The analytic theory of the motion of air in contact with flowing water is far from simple, it involves among other factors, the shape of the air and water ajutages. The degree of certainty of its conclusions would not, in the present case, compensate for its abstruseness. The adjustment of the water and air supplies must remain facultative, whether or not, as contended by Mr. Frizell, that adjustment is invariably automatic.

Starting from the conclusion of his experiments, that fine air-bubbles rise in the water at an approximate velocity of nine inches per second, the velocity varying as the square of their diameter, it is evident that water must enter the induction pipe at a speed materially greater than that figure, the more so, as all available records of tests on entrainment devices point to a low efficiency. Furthermore, the necessary velocity, and consequent loss of head, will be reduced by subdividing the entering air into minute bubbles, as done in the Taylor compressor.

Experience has set some practical values of the proper velocity, which is said to be from 12 to 16 ft. per second.*

The first step, in designing such a machine, is to assume a definite value for that velocity, for instance, 14 ft. The weight of the column of water to produce that velocity is 190 lb. per sq. ft., but it may be taken as 250 lb. to cover frictional and other losses.

If R is the volumetric ratio of free air to water at the head of the induction pipe, d the weight of one cubic foot of free air, P_0 the atmospheric pressure, and P_1 the absolute receiver pressure desired, both in pounds per square foot, the weight of one cubic foot of mixed air and water is:

At the top of the induction pipe: $\frac{62.4 + dR}{1 + R}$

At the bottom of the induction pipe:

$$\frac{62.4 + dR}{1 + R\,\frac{(P_0)}{(P_1)}}$$

Giving an average value:

$$\frac{62.4 + dR}{2}\left[\frac{1}{1 + R} + \frac{1}{1 + R\,\frac{(P_0)}{(P_1)}}\right] = m$$

If we assume H to be the height of the induction pipe and h that of the pressure pipe; we may write, as a first conditional equation:

$$mH = 62.4\ h + 250 \quad (1)$$

E being the efficiency of the process, and the compression being isothermal, another relation, when c = cubic feet of water and v_0 cubic feet of free air per minute is:

$$62.4\ cE\ (H - h) = P_0\ V_0\ \mathrm{Log_e}\ \frac{(P_1)}{(P_0)} = P_0\ R_c\ \mathrm{Log_e}\ \frac{(P_1)}{(P_0)} \quad (2)$$

But

$$P_1 - P_0 = 62.4h$$

so that at sea-level, for instance, equation (2) becomes:

$$0.0295\ E\ (H - h) = R\ \mathrm{Log_e}\ (1 + 0.0295\ h) \quad (3)$$

*Gibson's 'Hydraulics and Its Application.'

The air-pressure is a known quantity, and so is the working-head (H-h) so that E and R may be determined from equations (1) and (3).

This will give a first idea of the combination of the assumed numerical values, but a more accurate estimate of the detailed elements is, of course, necessary for different velocities in the induction pipe; the separation of air from water is the most important contributory factor of the efficiency, as the proportion of air passing to the tail-race either in suspension or in solution, affects the back pressure. It hardly need be said that aside from the computable data, the practical results of existing installations have to be taken into careful consideration.

The dominant feature of the hydraulic process is a considerable reduction in operating and maintenance expenses as compared with mechanical installations. For great capacities and high air-pressures, the first cost might reach large figures yet would compare favorably with that of a regular power-plant of the usual types, while the obtainable efficiency is decidedly higher. For small mines or tunnels, remote from manufacturing centres and difficult of access, the system should prove valuable in many cases.

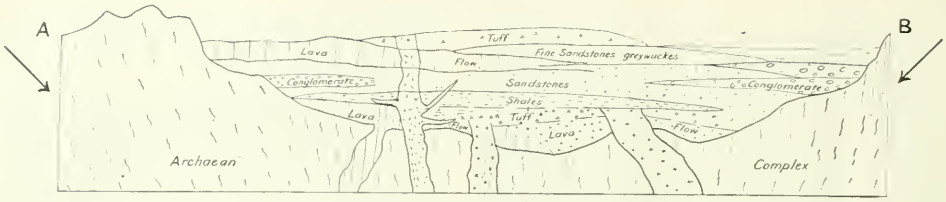
A Location Notice

Our contemporary the *Contact Miner*, of Nevada, publishes the text of a location notice found on the Granite range. It was dated June 11, 1889 and was found on ground that bore no evidence of ore. It is in poetic diction, but, for fear of shocking our readers, we give it in prose form.

"We, the undersigned men of worth, just to show we are on the turf, do hereby locate for ourselves alone, 1500 feet radius around this stone, together with mineral and water rights, all placer lands and townsites. We claim all ledges and veins within our lines, of brass, gold and other mines, and all coal and oil as well, from the top of sagebrush down to hell, and all the air and sunshine, too, up to where the sky shines blue."

Protective paints upon metal that is to be embedded in concrete structures, in order to prevent any damage that might be caused by electrolysis, has been proposed. No tests have been made that have determined what type of coating is best suited for the purpose. It would appear from first consideration that a paint capable of forming a film of high electrical resistance would be most efficient. Such films, however, generally present a high gloss surface and are apt to prevent the proper bonding of the concrete with the painted metal, thus doing more harm than good. It is chiefly for this reason that engineers have not generally adopted the use of paint upon reinforcing metal.

Fuller's earth production of the United States in 1914 amounted to 40,981 tons worth $403,646, an increase of 2387 tons. There were fourteen producers.



Section showing probable origin of older rocks of Kalgoorlie region (now represented by older greenstones, calc-schists, sheared conglomerates etc) before they were folded and intruded by the Igneous Complex shown in Plate II.

FIG. 1.

The Geology of Kalgoorlie

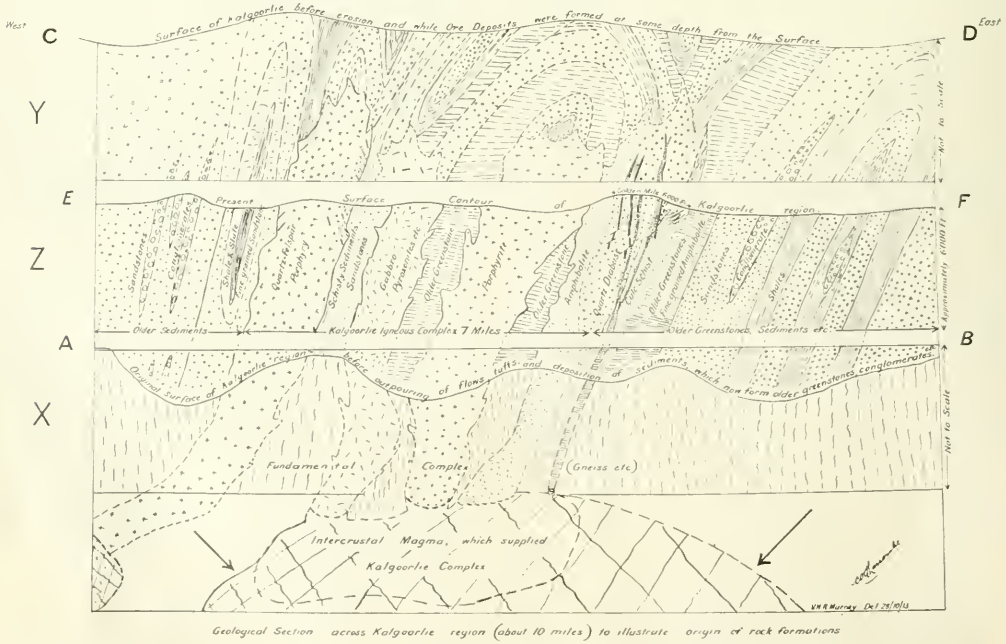
By C. O. G. LARCOMBE

THE SLATEY STRUCTURE. The so-called 'slates' have been described in some detail in my book on the geology of Kalgoorlie, but since the publication of that work I have carried out many observations with a view to determining their economic effect on the lodes, and their mode of occurrence.

I am now certain that on the Golden Mile the carbonaceous 'slate' has three modes of origin: (1) from the quartz-dolerite, (2) from the felsite (albite-porphyry), and (3) from the calc-schist.

In each case the slate is formed along lines of maximum shearing. From its general appearance one would be inclined to think that carbon was the chief constituent, but as a matter of fact the slatey structure marks a silicified zone. As a rule the structure is that of a cleat or joint of carbon not much thicker than a quarter of an inch, surrounded by cherty quartz passing outward into sheeted aphanite zones, though in places the cleavage does not completely obliterate the character of the original quartz-dolerite.

The plan of the 2630-ft. level of the Golden Horse-Shoe mine clearly shows the distribution of the slatey structure in felsite and quartz-dolerite respectively. I have not had much experience with the 'slate' in calc-



Geological Section across Kalgoorlie region (about 10 miles) to illustrate origin of rock formations

FIG. 2.

schist, but the slatey parts of the quartz-dolerite and felsite vary in strike and dip. They may be less than an inch in length, or they may be dozens—even hundreds—of feet. The more persistent bands strike north 40° to 45° west and dip between 65° and 75° in a westerly direction.

Relation to Lodes. It seems quite clear that the slatey structure in both quartz-dolerite and felsite was caused before the lodes were formed. There are many diverse opinions as to the effect of the 'slate' bands on the lodes. Since these are older than the lodes, the question is often asked: why do we not get rich ore with the carbon? As already stated, the actual amount of carbon is small, often no thicker than a sheet of paper, while the slatey bands are composed essentially of cherty silica, thus forming powerful silicified zones.

In the very highly altered zones, where there has been much differential movement and consequent change in strike and irregular distribution of the slatey silicified bands, it would appear as if the shear-line controlling the lodes must weaken. This caused the solutions to scatter, the 'slate' zones forming impenetrable barriers, with a consequent reduction, if not absence, of the precious metals.

The felsite 'slate' seems to me to be the worst in this respect.

But the more continuous bands of slatiness in the quartz-dolerite, such for instance as that on the 2480-ft. level of the Golden Horse-Shoe have no detrimental effect; in fact, in this case the 'slate' has acted as a barrier against which the solutions were allowed to concentrate. At this particular point one of the strongest enrichments was found. The occurrence may be seen in Fig. 3.

Origin of the Carbon. There has been much discussion as to the genesis of the carbon in these 'slates,' and the fact that the latter occur entirely within an igneous rock has tended to stimulate the controversy.

In a bore at the 1048-ft. level of the Associated Northern mine gas was given off containing 42.5 to 56.5% of methane.[1] Another report states:[2] "Carbonic acid gas is met with in some boreholes. One in the Lake View Consols has given off this gas for the past two years."

After closely investigating the question I am convinced that

1. The carbonaceous deposits are formed along shear-lines in the quartz-dolerite, felsite, and calc-schist.

2. In some cases the carbonaceous material is associated with quartz, pyrite, and ordinary gangue-minerals in open fissures, as in the main west cross-cut, 62 ft. from the main shaft at 2650 ft., in the Great Boulder mine.

3. In the first case the carbon is probably derived from solutions, possibly of oxides.

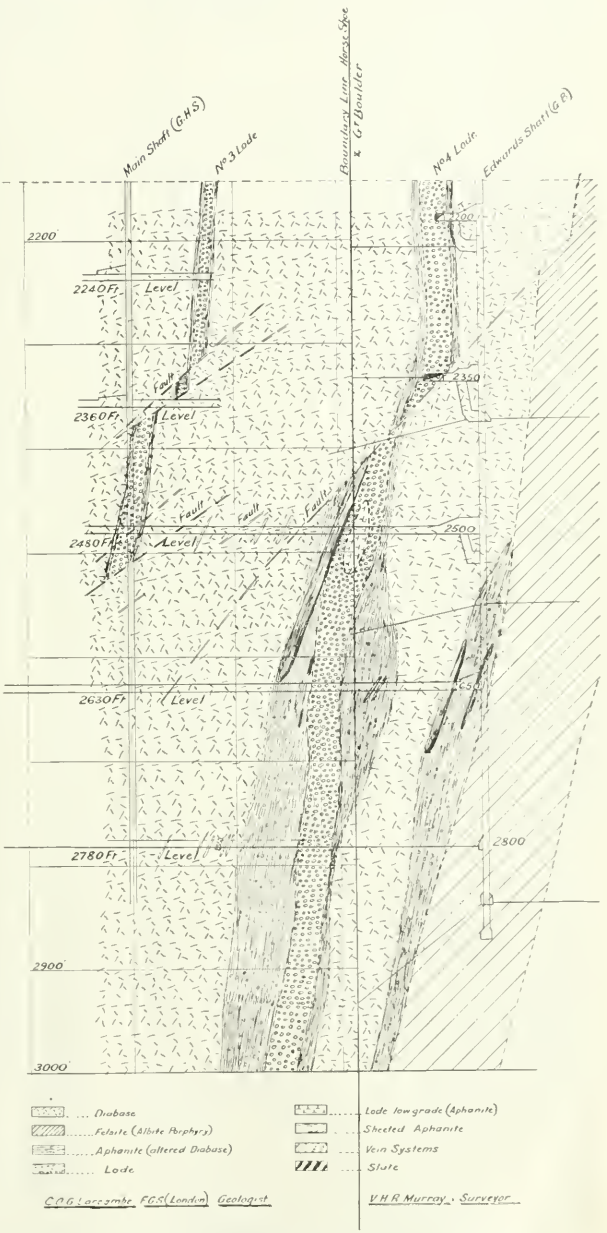


Fig. 3. Transverse Section, Golden Horse-Shoe.

[1] 'The Geology and Ore Deposits of Kalgoorlie,' Geol. Surv., W. A., p. 159.

[2] *Engineering and Mining Journal*, January 23, 1902, W. A. Prichard.

4. The mere fact that with the graphite veins are the same minerals that characterize the lodes and enclosing rock suggests a genetic connection between the veins and the metamorphic phenomena. In reality the quartz and other gangue-minerals represent contemporaneous crystallizations with the graphite.

Recent investigations in the graphite deposits of Ceylon and Dillon,[3] and the experiments of Van Hise, afford abundant support for my contention of origin from solutions. The constituents of the quartz-dolerite have crystallized at high temperatures from silicate solutions, and since the temperature of vaporization of graphite is known to be 3000°C., a temperature it is impossible to conceive the quartz-dolerite to have ever attained, the idea of sublimation from carbon vapors is scarcely tenable. We know that later chemical metamorphism generated much carbonate material, while there was much water shown by the phenomena of cementation at every level. Consequently the most feasible suggestion is that the graphite before deposition must have existed in the solutions in the form of some compound of carbon.

E. S. Simpson says: "In all these cases there would appear to be a direct connection between the gas and the graphitic schists, the gas being encountered either actually in such rocks or in fractured rocks close to, and in direct communication with them. This lends support to the theory held by the writer [Simpson] and apparently by A. Montgomery, State mining engineer, that the graphitic 'slates' found in lenticular masses in the heart of large areas of amphibolite and greenstone schists, at Kalgoorlie, Cue, Coolgardie, and elsewhere, are in reality shear-zones in the greenstone into which hydrocarbons of volcanic origin have penetrated, depositing finely divided carbon in them during slow combustion. This oxidation may have been at the expense of oxygen in the pores of the rock, or at the expense of ferric compounds capable of reduction to a lower state of oxidation."

This suggestion seems plausible, since hydrocarbons, especially methane, are found among the gaseous constituents of igneous rocks and in volcanic gases. But an argument against the above idea is that the carbon is so closely associated with vein-formation, which does not take place at high temperatures, whereas I can so far find no literature to show any reactions for the decomposition of hydrocarbons—with formation of graphite—below 500°C., the temperature expected under the conditions of vein-formation. It is therefore more likely that the methane is formed as an after-effect, for the graphites were powerfully slickensided after their formation, though some hydrocarbons may have been left undecomposed.

Weigert's[4] researches throw considerable light on the subject, for he has proved the reversible reactions:

$$C + 2H_2O \leftrightarrows CO_2 + 2H_2$$
$$2C + 2H_2O \leftrightarrows 2CO + 2H_2$$

and also that below 500°C. the CO_2 and H produced tend to react to make water and graphite.

In view of these facts it is only reasonable to expect graphite deposits along shear-lines at great depth, where the gases cannot escape.

In the case of Kalgoorlie, I strongly incline to the opinion that the formation of the carbon is due to the de-oxidation of carbon oxides that existed in the vein-solutions and along the sheared lines.

THE FELSITE or albite-porphyry has recently come into prominence on account of its somewhat large development in the Ivanhoe mine, and the recommendation of Dr. Malcolm Maclaren to sink the main shaft on that property to 3470 ft. and then cross-cut with the hope of picking up the lode on the foot-wall side of the felsite dike.

In various parts of the district this dike possesses a most characteristic pink color, but at deep levels it is a compact pale greenish rock, in many cases practically indistinguishable from the aphanite or altered quartz-dolerite. Moreover, both felsite and aphanite carry slatey bands that increase the alteration and thereby render separation almost impossible. It was for this reason I did not attempt to separate the felsite from aphanite in my original work, and only two dikes were recorded at deep levels. These were positively identified in a bore put out in an easterly direction from the 2350-ft. level from the main shaft in the Great Boulder mine.

But for economic reasons I have carefully investigated the question. I realized that if Dr. Maclaren's remarks held good as regards the Ivanhoe mine there would shortly be trouble in the Horse-Shoe ground, and the manager of the latter kindly allowed me to make a close investigation of his property.

Dr. Maclaren says: "The Ivanhoe east lode enters the porphyry (that is, the felsite) at 2800 ft. on the southern boundary," or, in other words, the northern boundary of the Horse-Shoe. I have proved that the foot-wall of the felsite at this depth is in the main shaft of the Great Boulder or a few feet to the east.

Judging from these remarks, and the calculated position of the Ivanhoe east lode at this depth, the felsite on the northern boundary of the Horse-Shoe would be certainly not less than 350 ft. wide, and possibly more. I know the felsite continues at least 2000 ft. north of this point. Consequently such a powerful body as this would surely go through the Horse-Shoe ground, with detrimental influence on that property. But after examining about 200 rock-sections from the Golden Horse-Shoe and Great Boulder properties, I am convinced that much of the so-called porphyry (felsite) is aphanite or altered quartz-dolerite. Moreover, the felsite has a dip of 73° and a strike of N.44°W. between the 1500 and 2800-ft. levels. If this dip is continuous, and if we take the foot-wall of the felsite as being 20 ft. east of the Great Boulder main shaft at 2800 ft., then the maximum thickness

[3]"A Theory for the Origin of Graphite as Exemplified in the Graphite Deposit near Dillon, Montana," A. N. Winchell, *Economic Geology*, Vol. VI, No. 3, 1911, p. 218.

[4]Abegg's Handb. Anorg. Chem., III, 2, 1909, p. 196.

of the felsite would be about 250 ft., a fact confirmed by the Ivanhoe bore put out from the 2870-ft. level. But I doubt if the actual felsite is as much as 250 ft. wide (Dr. Maclaren says 340 ft.), a fact of much importance to the Ivanhoe mine, for in the latter case the lode will enter the quartz-dolerite (beneath the felsite) at a less depth than anticipated. The 2800-ft. level of the Horse-Shoe mine shows the possible western edge or hanging wall of the felsite, which is no doubt considerably different from that of Dr. Maclaren. Fig. 4 shows the position of the felsite dike at 1650 ft. between the Hamilton and Edwards shafts. I have prepared Fig. 5 to show the possible position of the felsite from the surface to 3300 ft. between the Edwards and Horse-Shoe main shaft.

Dr. Maclaren says: "I have, however, gained the impression that the dike will flatten, and it will not persist as steeply as might be inferred from the last observed dip," but I have seen nothing in my examination outside of the Ivanhoe mine to support this idea of flattening. Furthermore, as far as one can judge, the boring in the Ivanhoe does not appear to have confirmed it as shown in Fig. 6, which I have prepared from informa-

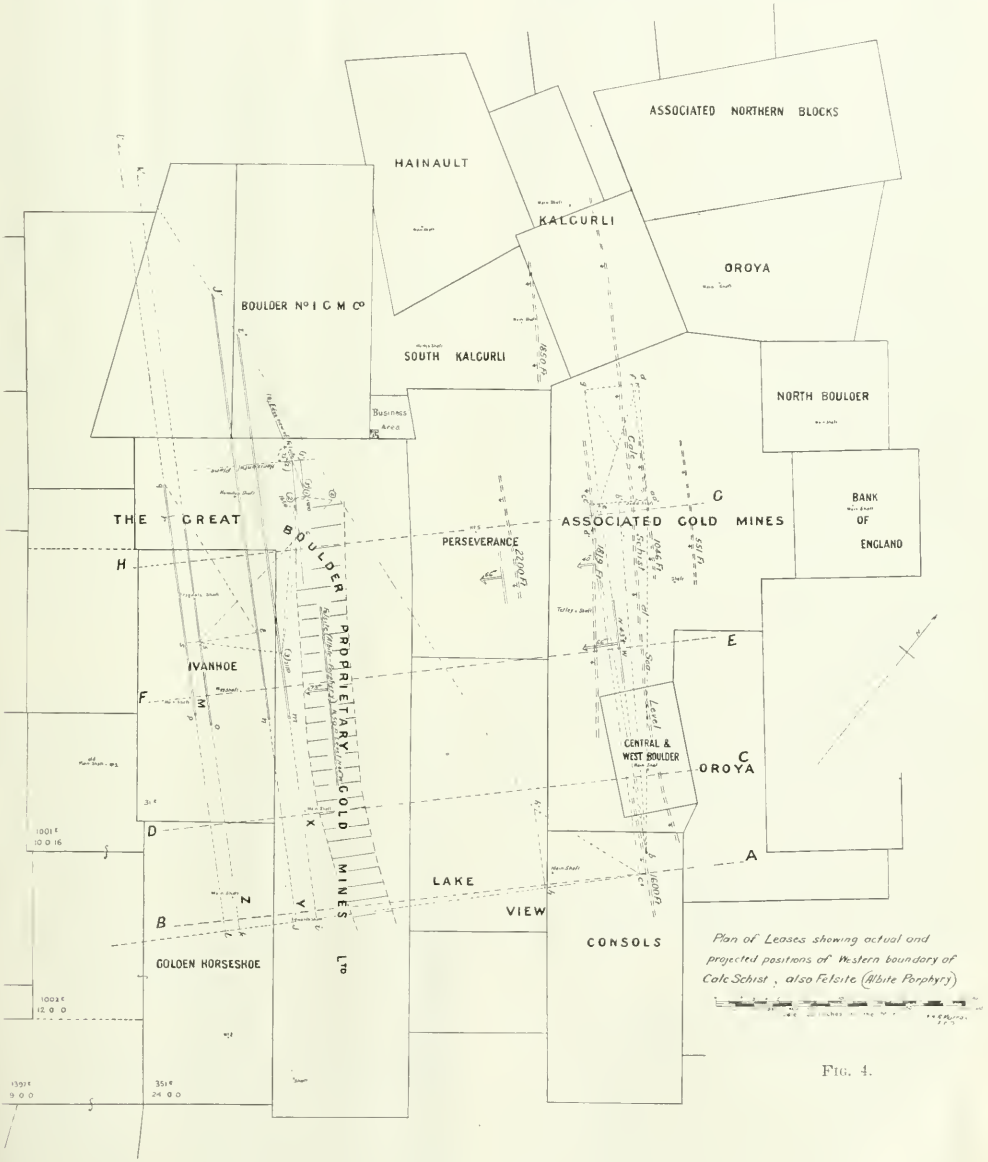

Fig. 4.

tion culled from reports, to endeavor to show the possible conditions revealed by the Ivanhoe bore put out at an angle of 39°30′ from 2870 ft. The dotted lines represent the position of the felsite as anticipated by me. In fact, at the southern end, opposite Edwards shaft, I am inclined to think the dip of the felsite at 2800 ft. is greater than 73°: this is indicated by the cross-section of the Great Boulder, which Mr. Hamilton kindly allowed me to examine.

Relation of Felsite to Lodes. It is quite clear that the felsite is older than the lodes. The shearing forces that produced the slatey bands in the felsite and quartz-dolerite, respectively, are also prior to the formation of the lodes; consequently, the felsite 'slate' is older than the lodes.

My experience has been that although the lodes pass into the felsite their gold-contents are either low or erratic and patchy. This is particularly the case where lodes enter slatey zones, especially when such zones make an acute angle with the lodes. The 'slates,' being very highly silicified and cherty zones, cause the main-lode shear-lines to split to a certain extent, thus causing an unequal and wide distribution of ore-bearing solutions and consequent erratic distribution of ore. Apart from this fact altogether, the felsite is inherently a tougher rock than the quartz-dolerite and is more resistant to the forces of shearing. In addition, it does not appear to me to offer the same inducements to replacement as the quartz-dolerite. The felsite therefore cannot be looked upon as a kindly rock for ore-formation, but it is of the highest importance to realize that the lodes do live in the felsite, and I agree with Dr. Maclaren this far, that if the shear-zones are able to withstand the resistance offered by the felsite over 700 to 900 ft. (on account of its steep dip) there is no geological reason why ore should not make again on the foot-wall side of the felsite. But with my knowledge it would be rash to predict any possible ore at such a depth, more particularly as there is a tendency for epidote to develop in the quartz-dolerite in depth.

The question is frequently asked: Why does not the Boulder get ore on the foot-wall side of the felsite. So far it has not, but this cannot be used as an argument in the case of the Ivanhoe, because the Great Boulder management has not followed the lode through the felsite.

The calc-schist has been the cause of considerable discussion of late, owing to the following statement by Dr. Maclaren in his report on the Kalgurli mine.

"Five other important mines (besides the Kalgurli) have suffered in the same way, together with several smaller mines. The experience of all these is identical, namely, that beyond a certain short distance (generally less than 100 ft.) beneath the quartz-dolerite, lode-channels fail to carry ore."

As far back as 1910 I penned the following remarks: "Another point is that, as shown in the general section across the field (Fig. 2) the metamorphic tuff (calc-schist) tends to dip to the west, and the position of this rock at various levels should also be marked, for, if lodes pass into the metamorphic tuff (calc-schist) their continuance will be doubtful. On the other hand, the contact of the metamorphic tuff (calc-schist) with the quartz-andesite (quartz-dolerite) might perhaps be regarded as a favorable zone for the occurrence of ore."

C. Gibson, in his report to the Geological Survey, says: "In economic importance the calc-schists probably rank next to the quartz-diabase (quartz-dolerite), many auriferous deposits of considerable importance occurring within them; these, however, have so far been at no great distance from the newer intrusives." He says further:

"No quartzose orebodies occur in this series of rocks, the lodes being similar and behaving similarly in every way to the schistose and carbonated ores found in the diabase, and the same general remarks apply equally well to both. As a general rule, however, they are more patchy in their contents and on the whole of lower grade than the latter class of deposits."

During last year I carefully examined the western margin or hanging wall of the calc-schist with a view to determining its position in various parts of the district. In order that the actual conditions may be more clearly grasped, I have prepared the plan (Fig. 4).

The plan shows the western edge of the calc-schist at 551 ft., 1046 ft. above sea-level, and 1819 ft. in the Associated mine; at sea-level and 1850 ft. in the Kalgurli mine; 1600 ft. in the Lake View Consols, and 2200 ft. in the Perseverance mine.

For the projections three points were taken:

Point.	Depth.	Mine.
a	1046	Associated
b	1600	Lake View Consols
c	1819	Associated

By projecting on to *ab*, the line *gcb* was found to be the strike N.43°5′W. From the projection to the left of *ac* the dip was found to be 66°. Consequently, down to the 1819-ft. level of the Associated, the dip of the hanging wall of the calc-schist is about 66°. A second construction (not shown on plan) gave a dip of about 40°, after a depth of 1750 ft. But how far west this lower angle of dip is to be continued nobody knows. I projected the point *c* to *c″*, and by drawing the horizontal line *c″l* the depths to which the Great Boulder Edwards, Horse-Shoe, and Ivanhoe shafts must be sunk below their present bottoms to meet the calc-schist can be worked out, as the plan shows, namely, by projecting a line through the shafts mentioned on to the horizontal line *c″l*, measuring off *im*, *jn*, etc. (the difference between the depth of the point *c* and the bottoms of the respective shafts) and measuring off the distances left, namely, *mi′*, *nj′*, etc. On the other hand, *c″h* represents the horizontal distance over which I think the calc-schist continues at a dip of about 40°. I then carried the dip back to 66° *h′l′*. That this construction is possibly near the mark is shown by the fact that no calc-schist occurs in the bore put out 300 ft. east from the main shaft of the Great Boulder at 2800 ft., while the bore east from the Ivanhoe shaft at 2870 ft. is still in quartz dolerite

(Fig. 6). The latter bore was carried a distance of 712 ft. into the Great Boulder ground at an angle of 39°30′.

From these data the calc-schist should be cut in the shafts mentioned at or about the following depths:

	Feet.
Main shaft, Great Boulder	4803
Edwards shaft, Great Boulder	5046
Horse-Shoe main shaft	5750
Ivanhoe main shaft	6019

It is hoped that these deductions will turn out to be correct, for when we come to consider that the quartz-dolerite forced its way up the western limb of an isocline in the calc-schist there seems to be every justification for continuing the dip of 66° after a horizontal heave of 500 ft., especially in view of the evidence afforded by the bores just mentioned.

From the foregoing remarks it is clear that there is a similarity of opinion between Dr. Maclaren and myself as to the general behavior of this rock, but I am inclined to take a distinctly more optimistic view for the following reasons:

1. From figures kindly supplied by the Chamber of Mines, I find that the calc-schist has yielded gold to the value of close on £7,000,000, and a rock that can yield so much gold above a vertical depth of 1200 ft. should not be neglected.

2. The Eclipse mine is entirely in calc-schist.

3. The foot-wall of the Oroya ore-shoot in the Associated Northern ground at the No. 5 level is 200 ft. from the quartz-dolerite contact. This leaves a fair margin.

4. The Perseverance mine has ore in the calc-schist.

5. The change in dip of the calc-schist at 1750 ft. is probably due to an old fault. This may afford possibilities.

6. Ore has been found in the calc-schist down to 2200 feet.

On page 117 in my book I said: "The ore-occurrences on the eastern side of the Golden Mile are quite unique, and differ altogether from the lode formations that dominate on the western side of the field. The country-rock on the east is also different from that on the west.

"The bulk of the ore is derived from orebodies along large fault-planes, and zones of impregnation at the junction of faults. It is to this class that the famous shoot of ore which commences in the Brown Hill, passing through the Associated Northern, Oroya, and finally the Associated mine, belongs." On page 127 I further remark:

"There seems to be much more geological work required on the eastern side of the field, to prove not only the direction of fault-planes likely to carry ore, between the two dominant outer planes, but also the possibility of parallel fissures."

Finally, on page 287, I remarked: "It is hard to believe in country like that on the eastern side of the field, where the ore grows on three large fault-planes, there should not be more faults of a similar nature."

Of course, when it comes to a question of deep sinking in the calc-schist I fear I cannot recommend it, for the trouble is that this rock apparently passes downward

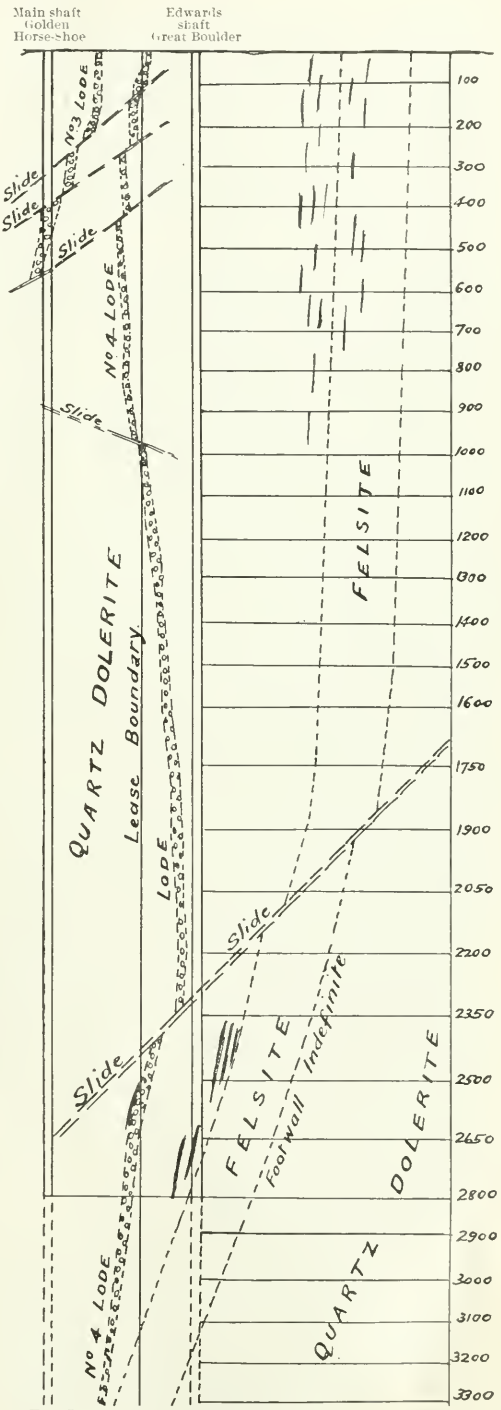

FIG. 5. TRANSVERSE SECTION OF GOLDEN HORSE-SHOE AND GREAT BOULDER.

into fine-grained amphibolite, which we have no reason to believe contains auriferous deposits; and below this we have the barren sediments as shown in my cross-section of the field (Fig. 1 and 2).

However, as shown in cross-sections, it is clear that the life of the western mines is not affected by the calc-schist, for, although at 1750 ft. the calc-schist flattens to angles as low as 36°, I am of opinion that it will return to its normal dip and so not come into the western mines much before 5000 feet.

However, I am still hopeful that new orebodies may yet be found in the calc-schist, for I see no reason why they should not if the necessary fault-planes or sheared-lines exist, and I think the recent developments in the Oroya Link leases at depths not far short of 1000 ft. strongly support this contention.

The Quartz-Dolerite. So much has been written about this rock by Dr. Maclaren,[5] Geological Survey,[6] and myself[7] that there is little to be said in the way of description.

But my recent investigations have brought to light certain economic phases in the development of the rock that have a bearing upon the economic feature. First, there is a very basic variety containing much epidote developed along the eastern edge of the quartz-dolerite in the Perseverance mine on the 1900-ft. level. Although it is believed that the epidote-bearing variety, which passes into epidote-amphibolite (epidiorite) is not a favorable sign, my examination showed that in this instance the differentiation is only local, for the normal type is again present on the 2200-ft. level.

An interesting rock, which undoubtedly belongs to the Boulder type, was examined from a bore 600 ft. deep, put down on the southern end of Lease 4236E east of the Brown Hill townsite. No quartz-dolerite is shown at this point on the Geological Survey map, and the particular rock described, which is east of the calc-schist, evidently belongs to the Brown Hill branch mentioned by Dr. Maclaren. It is regrettable that no lodes have yet been reported in this rock. Another point is that a certain amount of epidote develops in the dolerite at depths of 2800 ft. on the western side of the district, and it is important to watch the influence that this change is going to have on the lodes in depth.

General. For the information of those unacquainted with the geological structure of Kalgoorlie, I have drawn cross-sections (Fig. 1 and 2) over 10 miles of country, in order to show the probable relationship existing between the various rock formations.

From these cross-sections it will at once be seen that after all the Golden Mile, the local name for the gold-bearing area from which most of the gold has been won, forms only a small part of the entire width—about 6000 ft.—characterized by the intrusion of quartz-diabase (quartz-dolerite) with the associated calc-schist and felsite (albite-porphyry).

[5]Mining and Scientific Press, August 2, 1913, pp. 189-90.
[6]"Geology of Kalgoorlie," pp. 56-65.
[7]"The Geology and Ore Deposits of Kalgoorlie," pp. 22-30.

If we go far enough back into the geological history of Kalgoorlie, long before any ore deposits were formed, the conditions would be something like those shown in Fig. 1. Here we have a fundamental platform, marked Archean Complex (Dr. Maclaren's Sub-Kalgoorlie formation) on which was deposited a series of alternating lava-flows, ash-beds, sandstones, conglomerates, etc. As a result of the gradual cooling of the earth the crust continued to contract on a shrinking nucleus, and was in consequence subjected to enormous strains and stresses, which resulted in the folding of the lava-flows, etc., in the same way as a sheet of paper is crumpled under lateral compression, the amount of compression being just sufficient to cause the limbs of the folds to be almost parallel (isoclines), but with a steep dip westward.

During the process of folding, the original rocks were changed as follows:

Original rock.	Now represented by
1. Lava-flows	Older greenstones.
2. Tuffs or ash-beds	Calc-schists (though these are in some cases more likely the altered edge of the older greenstones).
3. Conglomerates	Sheared conglomerates.
4. Sandstones	Hardened sandstones and micaceous quartzites.
5. Shales	Hardened shales, slatey rocks, and micaceous schists.

Up to this time, before any intrusions forced their way to surface, the Kalgoorlie terrain consisted of the altered representatives of the older rocks, and the surface of Kalgoorlie was no doubt much higher than it is now, but still probably of the nature of a tableland, and represented by the line *C D* in Fig. 2.

In those days, as at the present time, there existed great reservoirs of molten rock furnishing material, not only for the various intrusive rocks—granite, gabbro, etc.—of the earth's crust, but also the great flows of lava that from time to time have been poured out over the surface of the land.

Some such reservoir as this is shown at the bottom of the drawing. From this magma the various igneous masses that are characteristic of the Kalgoorlie region were no doubt derived by the ordinary processes of differentiation. The chief rocks that separated out from the magma were gabbros, pyroxenites, quartz-dolerite, porphyrite, and felsite (albite-porphyry) but farther south of the section peridotites appear.

The actual order of separation does not cut much figure from an economic point of view, but we know that the quartz-dolerite and felsite are the intimate associates of the gold, and at least that the felsite dikes were the last product to separate, for they forced themselves through both calc-schist and quartz-dolerite.

The quartz-feldspar-porphyry at Binduli, on the left side of the section, has been referred to as a separate magma in the direction of Coolgardie.

It seems quite feasible to suggest that the forces that folded the older rocks acted on the intercrustal magma, and so caused the igneous masses to be forced toward the surface along the limbs of the isoclinal folds, as we

know was the case with the quartz-dolerite, which came up from the west at an angle of about 66° along the western edge of the older greenstone, in part converting the edge of the latter into calc-schist.

During the period of these intrusions the surface of Kalgoorlie was much higher than it is now (see *C D* in Fig. 2), and the tops of the intrusions were some distance beneath the surface.

Crustal forces must have still been in evidence, for up to this time no ore deposits had developed, so that sheared lines were later formed in the quartz-dolerite and felsite (for both rocks are older than the lodes). It was along these sheared lines that the process of ore deposition continued to operate with the ultimate production of rich lodes. As yet the surface of Kalgoorlie was still represented by the line *C D*, and it was not until ages of erosion, when the surface was worn away to *E E* that the lodes were exposed.

In concluding this paper I must express my sincere thanks to the various managers in the district, especially J. W. Sutherland, general manager at the Golden Horse-Shoe mine, for kindly allowing me to use the plans prepared in connection with my report on this mine. I also owe much to V. H. R. Murray for the great care he has taken in the production of the various plans and sections, as well as F. W. Rowe, who made the microscopic sections upon which my conclusions have been based.

[Publication of this interesting article by the Lecturer on Geology in the Kalgoorlie School of Mines has been delayed. The following notes bring development up to the end of May 1915: At the Ivanhoe the main shaft is down to 3345 ft. from the surface, in country assaying a trace of gold. A cross-cut eastward has been started from the shaft at 3320 ft. At the end of 1914, a diamond-drill completed a hole from 3170 ft., going east at 38° to explore the porphyry dike, which was cut at a vertical depth of 3297 ft., and 184 ft. east of the shaft. It continued to 409 ft. east, equal to a depth of 3475 ft. At 262 ft. 6 in. the hole passed through 33 in. of material assaying a trace. This is the East lode, and is 32 ft. farther west than at 3067 ft. The porphyry is 31 ft. farther west. Nothing of interest was disclosed by the hole. Reserves of ore are estimated at 998,718 tons worth $8.94 per ton. At the Horse-Shoe mine the main shaft is down 3068 ft. A cross-cut is being driven east. The mine is estimated to contain 727,043 tons of $8.56 ore, of which 82,416 tons, averaging $15.30, is in No. 4 lode, which is near the boundary of the Horse-Shoe and Great Boulder properties. This lode at 2900 ft. in the Horse-Shoe has averaged 10 ft. in width as far as opened, worth up to $32.40 per ton. The south drift is in 182 ft. The Horse-Shoe made a profit of $43,500 in June. Ore reserves in the Great Boulder are estimated as 469,115 tons, assaying $15.14 per ton. No sinking has been done for about four years, or since the boundary lode passed into the Horse-Shoe ground.—Editor.]

Compound interest causes a sum of money to double in a period of years that is approximately 69 divided by the rate per annum: thus, if the rate is 3% the sum will double in 23 years. A French mathematician has calculated the value of a franc put at compound interest 2000 years ago and finds it to be equivalent to 162,260 spheres of pure gold the size of the earth; hence, a dollar, under the same conditions, would have grown to equal more than 800,000 golden worlds.

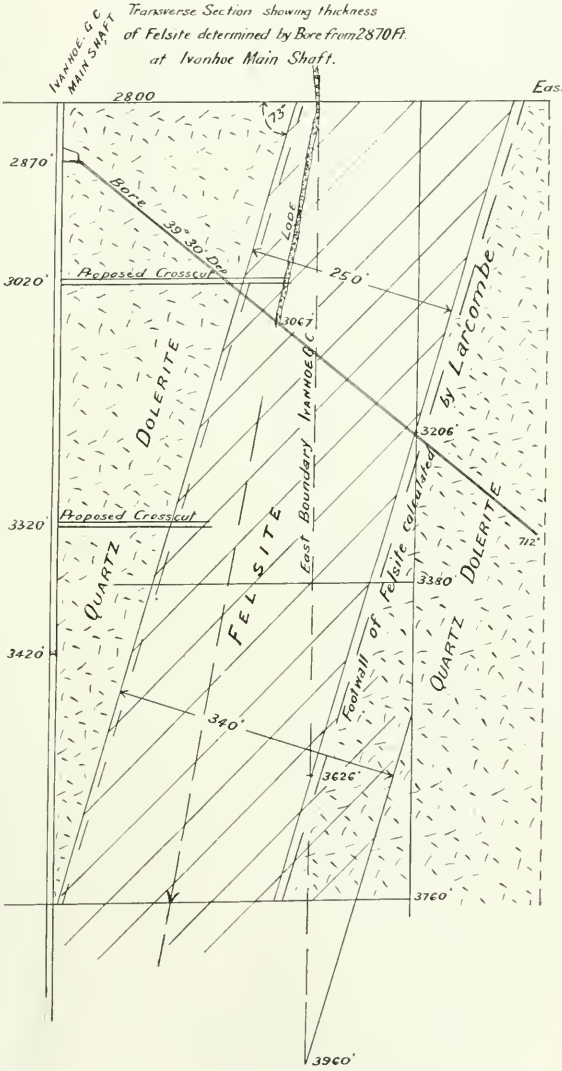

Fig. 6.

Mining in Arizona

By CHARLES F. WILLIS*

Miners, business men, and residents generally are happy over the prosperity that now pervades the State. Never were wages so high, never was the copper market in better shape, and never were the activities of the mining centres in more expansive mood. Conditions from a mining standpoint could hardly be better; all properties are working to capacity, and even with an overload; working forces are being increased wherever room can be made available. Although the price of copper has declined slightly during the month, it has not affected the increasing output of the mines of the State.

Among the events of the past month has been the revival of several old districts. The American Smelting & Refining Co. has started in this State with holdings in the Christmas and the Twin Buttes districts, and is now about to sink a few test churn-drill holes in the Silver Bell district, on the property formerly owned by the Imperial Copper Co., which was controlled by the Development Company of America and was a heavy producer up to 1909. In 1907 it yielded over 4,000,000 lb. of copper and 48,000 oz. silver. In 1908 almost 6,000,000 lb. copper and 68,000 oz. silver were produced. Then, with the blowing in of the Sasco smelter and the completion of the Arizona Southern Railway in 1909, about 15,000,000 lb. copper was produced. Litigation, terminating in a bankruptcy sale, brought the work to a close in the spring of 1915. Although it is not known who the purchasers really are, it is significant that shortly afterward the American Smelting & Refining Co. sent some churn-drills and started a systematic prospecting of the property. With the operations of the Copper Queen Consolidated in the Catalinas, the Cahmet & Arizona at Ajo, and the A. S. & R. at Silver Bell, it looks as though Pima county would come back to its old-time mining prosperity. The activity of these operators in Pima county has stimulated interest and caused others to start operations. L. D. Plankey and associates of Butte, Montana, have taken an option on the property adjoining the new holdings of the A. S. & R. in the Twin Buttes district and have purchased a diamond-drill for immediate prospecting.

The building of the railroad to the Magma mine in the Superior district is a reminder of the time when the famous Silver King mine made several millions of dollars in profit—from 1884 to 1886. The pinching of the orebody in 1887 caused the desertion of this once flourishing camp. On the Magma vein about 95,000 tons of copper ore has been developed, carrying 7.6% copper, 8.1 oz. silver, and 56 cents in gold. Reserves are rapidly increasing with the extension of the 1000-ft. level.

Another old producer has been revived at the property of the Kay Copper Co. in Black canyon. Although the main shaft has a depth of only 325 ft., the drifts and other exploratory workings are reported to show attractive conditions. Considerable quantities of ore have been shipped from this property in past years.

The Congress district is again active, but in a way different from heretofore. This district attracted attention in former years on account of the richness and persistence of the Congress lode. Much excitement was caused in the early days by the finding of considerable quantities of native gold on the tops of the hills. Although for many years these deposits furnished ground for 'dry-washing,' the persistent work of Messrs. Genung and Barnum in tracing the source of these dry placers has led to the uncovering of the old topography and the discovery of the ancient channel. Three hundred linear feet of exploration on this 'deep lead' has demonstrated that it is the source of the 'nuggets.'

The Phelps-Dodge Co. has invaded Mohave county and has optioned almost all the valuable claims in the Mineral Park basin. But little work has been done in this area, and even that in a rather perfunctory and haphazard manner, but considerable quantities of low-grade copper ore with occasional very rich ore have been uncovered in the surface-work. It is evidently the intention of the Phelps Dodge Co. to explore this basin by drilling.

The Harqua Hala is again coming into its own. Crosscuts run on the sixth level of the famous producer have encountered ore in both directions. Driving and raising on the orebodies are now in progress. This is virgin territory and both veins are of good milling grade. The Harqua Hala has produced more than $4,000,000 in gold in the past and bids fair to produce as many millions more. When it is considered that a vertical depth of only 200 ft. has been attained on this property, its production is little short of marvelous.

Tombstone, around which hangs a history typical of the early days of the West, is again taking on an industrial appearance in consequence of the efforts being made by the Bunker Hill Mining Co.—a Phelps-Dodge subsidiary. Tombstone was discovered in 1878. The ore contained gold, silver, and lead. At first silver was the principal constituent of the ore, but as the mine workings were extended in depth, it was found that the proportion of gold to silver rapidly increased, so that the value of the gold greatly exceeded that of the other metals. The camp became one of the largest in the South-West and produced about $35,000,000. At a depth of 560 ft. below the surface, the water-level was reached, where the flow was so great that all attempts to control it failed and the miners were obliged to dis-

*Director, Arizona State Bureau of Mines.

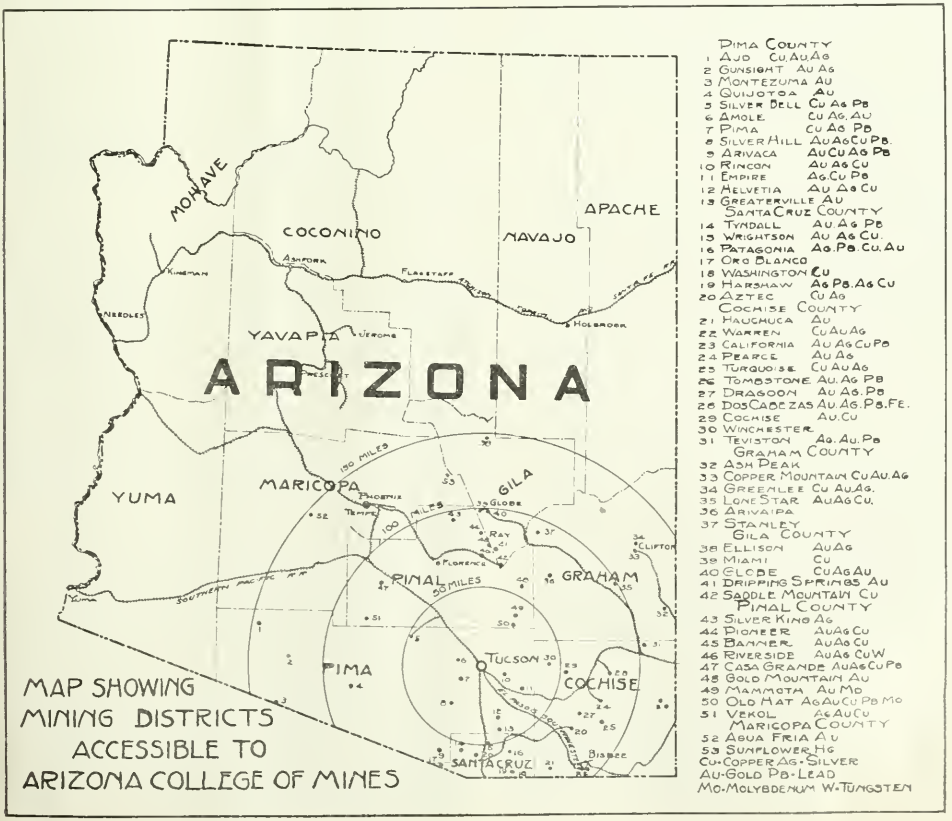
continue operations. The present owners are working a force of 300 men. Ore is now being milled from one of the old shafts; this ore averages between $5 and $7 per ton. The old tailing-dump is valued at about $4 per ton, and this also is being sent to the mill, which has been entirely re-modeled. The all-sliming cyanide process is being used. At the old shaft where millions of dollars were spent in a vain endeavor to drain the district, a modern pumping- plant is in operation and water is being raised to within 70 ft. of the surface, and is handled from there by an air-lift.

Construction plans have also been a notable feature of Arizona mining in the past month. A contract has been let for the construction of the Tucson, Ajo, & Gila Bend railroad and the completion of the Gila Bend-Ajo link is expected by January 1. Work will then be rushed on the Cornelia reduction works of 4000 tons daily capacity to handle the 40,000,000 tons of copper ore that has been developed. Leaching and flotation processes are to be used. Probably $5,000,000 will be expended before production begins.

Much activity in mill-building is evident in the gold-fields in the northwestern corner of the State. Three new mills are about to be erected and within 90 days it is expected that there will be two additional plants. Work is being rushed on the construction of a mill for the United Eastern mine, at Oatman, in order to derive a revenue as early as possible from the large body of high-grade opened up on the 460 and 565-ft. levels. The assay-value of this ore is said to be about $2,000,000 and it is being rapidly increased by the development work. The general average of the ore opened west of the shaft on the 565-ft. level is $36.60 per ton across a width of 22 ft. The initial unit to be erected will have a capacity of 150 tons daily.

C. E. Finney, of Los Angeles, representing the London-Arizona Copper Co., which has just sold the London-Arizona, the London-Range, London-Shamrock, and Ball groups to the American Smelting & Refining Co., has secured control of the M'Cracken silver mine, an old producer and arrangements are being made to place upon the property a 500-ton reduction plant to handle the $700,000 of ore said to be in reserve.

In the Wickenburg district, mills are to be erected for the Monarch and Grijavla mines. The Monarch is a copper-gold mine. The Grijavla Neavo Mining Co. is building a mill and tram to treat the 24,000 tons of ore now available. A pumping-plant of 150 gal. per min. capacity will deliver water from the Hassayampa river to the mill, a distance of 4000 ft. and an elevation



of 600 ft. The Grijavla is a coarse-gold lode and many pieces of considerable size have been found in its ore. The present company acquired control of the property only last April.

The striking of ore on the 1600-ft. level of the United Verde Extension Mining Co., in the Jerome district, has brought renewed vigor into its operations as well as giving its stock a decided boost. Improved facilities for handling the ore are under discussion and it is expected that a tram down the hill to the V. T. & S. Ry. will be built shortly as this would afford excellent shipping facilities to the Clarkdale smelter.

Gold has been found in the Christmas district, which has heretofore been actively mined for copper. The gold is coarse and ore averaging $200 per ton has been shipped. Although the presence of asbestos in Gila county has been known for some time, it has only just been shown to exist in commercial quantities and is of the long-fibred variety. The strike in the Commonwealth Extension, at Pearce, is proving larger with development work. Since striking the ore 80 ft. has been driven and the assays run from $20 to $60 per ton. It would appear that the Juniper Flats district will give Arizona another goldfield.

Oil Production of the World in 1914

The quantity of petroleum entering the markets of the world in 1914 amounted to 400,483,489 bbl. according to statistics compiled under the supervision of J. D. Northrop of the U. S. Geological Survey. They are as follows:

	1914.		1913.	
Country.	Production.	%	Production.	%
United States	265,762,535	66.36	248,446,230	64.59
Russia	67,020,522	16.74	62,834,356	16.34
Mexico	21,188,427	5.29	25,902,439	6.73
Rumania	12,826,579	3.20	13,554,768	3.52
Dutch East Indies	*12,705,208	3.17	11,966,857	3.11
India	†8,000,000	2.00	7,930,149	2.06
Galicia	†5,033,350	1.26	7,818,130	2.03
Japan	‡2,738,378	.68	1,942,009	.51
Peru	1,917,802	.48	2,133,261	.55
Germany	†995,764	.25	†995,764	.26
Egypt	777,038	.19	94,635	.03
Trinidad	643,533	.16	503,616	.13
Canada	214,805	.05	228,080	.06
Italy	39,548	.01	47,256	.01
Other countries	**620,000	.16	†270,000	.07
Total	400,483,489	100.00	384,667,550	100.00

*Includes British Borneo; †Estimated; ‡Includes Formosa; **Includes 600,000 bbl. produced in Argentina.

The total of the world since 1857 is 5,593,262,936 bbl., of which the United States yielded 3,335,457,140, and Russia, 1,622,233,845 barrels.

WATER in a heavy stream poured directly upon the chip at the point where it is being removed from the steel forging by the tool permits an increase in the speed and allows of a 30 to 40% increase in the amount of work done; with cast-iron the gain is 16%.

Oil in China

The Standard Oil Company of New York is said to be pushing operations in the Chinese oilfields and recent reports from China state that the National Oil Bureau is confident that an extensive supply will be found by the wells now being drilled. The latest news is that the company has stopped wells No. 1 and 2 in the Yen Chang district of Shensi and is boring new wells at Tuanchiawan and Huailiho. These regions had previously been surveyed by the company's geologists.

The above item is of great interest to one of our engineer friends, who tells us that he visited Yen-chang in 1899. At that time the Pekin Syndicate had a concession for any petroleum found in the Province of Shansi, which lies just east of the south-flowing Yellow river, while Shensi lies to the west. Extensive search for eight months, the placarding of the province of Shansi (which is about as large as England and Wales) and offering rewards running from a few taels (say, 70 cents) for report of oil indications up to 10,000 taels, to be paid after development of a well producing 100 bbl. per day, failed to bring out any oil in Shansi. The nearest approach to oil was an iridescent scum of iron oxide found on the surface of a quiet pool hidden in a deep ravine. This rainbow film was the only thing resembling oil to be seen in Shansi. It took 14 days steady travel to reach the pool.

Shensi, however, has been noted for its oil occurrences for centuries. Marco Polo, a geographical prodigy, was the first to speak of the "fire-fountains" of Shensi, but all memory of them seems to have been lost, as far as the local Chinese are concerned. No fiery fountains have been seen for generations. There is doubtless some foundation for the story.

Our mining engineer friend saw two oil-springs; one at Yen Chang Hsien, a miserably poor hamlet some miles west of the Yellow river. The geology of this part of China is simple: overlying a thick deposit of limestone is the shale of the coal formation and above this is found a brown sandstone of great thickness. The Yen Chang district is in this upper sandstone and the oil was found oozing out between the layers of the sandstone not far above the little stream on which the town is situated. The total amount of oil flowing was not more than a quart per day. Similar springs were said to be nearby. Another spring was seen some 30 miles away in a southerly direction. Here the ropey oil floated on the surface of a pool 30 ft. in diameter at the base of a sandstone cliff. The oil was skimmed off when wanted; and used as medicine; and also in lamps, when the crops failed and bean-oil was lacking. A peculiarity of the deposits is their occurrence in horizontal, or at any rate, only slightly disturbed strata. Oil experts in London, to whom the deposit was described, thought that the chances of developing an oilfield were not good, but the Standard Oil Company, with its wider experience, seems to have faith. Where oil indications are scattered over so wide a territory, it does seem that the chances for finding productive wells are good.

Concentrates

Readers of the Mining and Scientific Press are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

Fuel-oil vaporizes at 130° Fahrenheit.

The choice of power in churn-drilling cannot affect the cost except to a minor extent.

Calcium carbide (lime and coke) is made in an electric furnace at a temperature of 7000°F.

Falling water is an active resource. Power is inherent therein. If not captured, it is unused, unproductive, and wasted.

Fire-brick production, which accounts for 12.68% of the value of all brick and tile products of the United States, rises and falls with the fluctuations in the iron and steel and coke-making industries.

When using heavy oils in large oil-fired furnaces it is necessary to use oil or steam at 80-lb. pressure in order thoroughly to atomize the oil and distribute the heat, but in small furnaces 20-lb. pressure will suffice.

Ten 1360-lb. stamps at the Empire mill, Grass Valley, driven by a 35-hp. back-geared motor, use 31.5 horsepower. By the use of this style of drive a saving of about 5% was made, compared with the old drive.

Churn-drilling results at the Sacramento hill, Bisbee, Arizona, are being proved by underground work. One hole, which gave an average of 3.80% copper, has been followed by a raise that yielded 3.79% ore, showing good work.

A soldering composition for aluminum consisting of the following elements in substantially the following proportions: block tin, 80; lead, 16; aluminum, 8; zinc, 16; and phosphorus, 8 parts, is among the recent patents issued at Washington.

Formaldehyde is a water-white liquid, which, if of full strength, contains 40% formaldehyde gas. It has a strong odor, which, however, practically disappears in the diluted form in which it is generally used. It is a powerful disinfectant and antiseptic.

A man with an electric-hammer may be expected to do about as much work as six men working by hand. This is easily explained by the fact that a man with a hammer strikes from 50 to 80 blows a minute, while the electric-tool strikes from 1400 to 4000 in the same time.

Silver is chiefly produced as a by-product of copper and lead smelting. For example, 14 of the largest copper and lead companies in North America have a total annual output of 108,000,000 oz. silver, while the 14 largest silver companies have a total output of only 21,500,000 oz. Anaconda alone produces more than half as much silver as the total of the 14 silver-mining companies.

The efficiency of a reciprocating air-compressor is ordinarily stated as the ratio of the work done upon the air, as shown by an indicator-diagram from the air-cylinder, to the work performed by the steam, as shown by the area of the indicator-card taken from the steam-cylinder.

Fifteen stamps, one Chilean mill, and four grinding-pans at the Eldorado Banket gold mine, in Rhodesia, reduced 57,073 tons of ore in the year ended March 31. The duty was 5.25 and 84.07 tons for the first two machines. The three stages cost a total of $1.18 per ton treated.

Sulphur is successfully used in setting holding-down bolts for machinery. A cracked centrifugal pump was patched temporarily recently with a rich cement mixture, but the bond between this and the pump did not hold. Molten sulphur was then run into the crack, making a tight joint.

Viscosity of lubricants may be determined in the following manner: A metal strip is coated on both sides with the lubricant, and placed between two cylinders, held against it by weights. Known weights are hung on the strip, and from the relation between the various weights at equilibrium the viscosity is found.

High-speed steel is comparatively little understood, although a great deal of work has been done on it. It is a material which may be very complicated in composition. It may contain as essential constituents iron, carbon, silicon, manganese, tungsten, chromium, vanadium, molybdenum, and cobalt. Many of the ultra steels contain as many as eight of these elements. The range of composition of the English high-speed steels is as follows: carbon, 0.45 to 0.85; silicon, trace to 0.2; manganese, 0.1 to 0.5; tungsten, 8.0 to 18.0; chromium, 2.5 to 6.5; molybdenum, 0.0 to 2.0; vanadium, 0.0 to 1.5; and cobalt, 0.0 to 5.0 per cent.

Fusible-tin boiler-plugs have been reported as failing to melt and give warning. An investigation by the Bureau of Standards shows that the tin filling in these cases had become oxidized to tin oxide (SnO_2), which has a melting point above 2900°F. One pronounced and dangerous type of deterioration is the oxidation of the tin along the grain boundaries, by which is formed a network of oxide throughout the tin. This is shown to be due to the presence of zinc in amounts as low as 0.3%. Lead and zinc are found to be the principal impurities in tin-plug fillings, and since all 'failed' plugs contained these or other impurities, the conclusion is reached that if these impurities are eliminated by strict specifications and inspection, which will allow only admittedly superior qualities of tin, such as Banca and some others, the danger of failures of these plugs will no longer exist.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

CRIPPLE CREEK, COLORADO

Gold Output.—Cresson Dividends.—Hondo Development.—Drainage Adit.—Nagel Lease.—Compensation at the Portland.

The estimated gold production of the district in July is as follows:

Plants.	Tons.	Average value.	Gross value.
Smelters	4,000	$55.00	$220,000
Golden Cycle	37,000	19.00	603,000
Portland (Colorado Springs)	11,000	20.00	220,000
Portland (Cripple Creek)	17,800	3.05	54,290
Portland (Independence)	11,000	2.42	26,620
Wild Horse	850	3.50	2,975
Kavanaugh-Jo Dandy	400	2.00	800
Total and average	82,050	$13.74	$1,127,685

Although the tonnage treated in July was considerably larger than in June, the grade was a little lower. For this reason the total was less than in the previous month.

During July about $200,000 was paid in dividends. During the first quarter of the current year the Cresson Gold Mining Co. distributed $1,050,000. This includes a special dividend of $1,000,000 in addition to the regular dividend of 5% on its capital of $1,000,000. This company is a close corporation. It is reported that the dividend for the second three months is about the same as that given above.

A rich discovery was reported a few days ago in the property of the Hondo Gold Mining & Milling Co on the 'saddle' between Battle mountain and Bull hill. In sinking a winze from the 200-ft. level, 5 ft. of ore was opened. A rich streak of quartz-bearing sylvanite was found on the hanging wall. It is rumored about the east end of the district that this company will build a small mill this fall to treat the low and medium-grade ores which were exposed recently in sinking the shaft.

The directors of the Roosevelt Deep Drainage Tunnel Co. have decided to continue the work on company account. It is estimated that a little more than 8000 ft. of work remains to be done before cutting the main water-courses of the Golden Cycle mine. This work will be done as rapidly as possible. C. H. Fuller is in charge of operations. The Nagel lease on the adit level of the Portland mine is making splendid profits.

In a notice recently sent to each of its employees, the Portland Gold Mining Co. has decided to accept the provisions of the Workmen's Compensation Act. This provides for the payment of certain fixed compensation to employees for personal injuries accidentally sustained in working for the company. This act became effective on August 1, 1915. In order to supplement the benefits under this act, the Portland company placed before its employees two propositions, namely: (1) The new law provides benefits only for accidents sustained by the employee while engaged in his regular work. The Portland company proposes to erect in the Cripple Creek district a first-class hospital with modern equipment. This hospital will be open to all employees in case of sickness, as well as in all cases of injury through accident, whether such sickness or injury arises when the employee is on or off duty. The company will also furnish and equip, at its own expense, a first-aid office on its property, where immediate first-aid may be applied until injured persons may be cared for at the hospital. For such hospital, medical, surgical, and first-aid service the company will deduct $1.25 from the monthly pay of each employee. (2) Under the new law the employee receives no compensation whatsoever for the first three weeks of his disability through accident, nor does he receive any benefits during said period, except actual surgical and hospital aid, etc., not exceeding $100 in value. The Portland company proposes to form, with its employees, a mutual plan of insurance without assessment features. Each employee will be required to contribute 1% of his monthly wages. The company will contribute an equal amount. From this fund, contributing employees, while unable to work by reason of sickness or injury, will receive half pay during the first three weeks of disability. As a result of a vote, participated in by every employee of the company, the two proposals were unanimously accepted. This is but another example of the broad-minded, efficient, and far-seeing policy of the Portland company toward its workmen.

GOLDFIELD, NEVADA

Merger-Jumbo Extension Agreement.—Jumbo Extension Development.—Merger Capital.—Atlanta, Great Bend, Silver Pick.

The end of litigation at Goldfield, pending and threatened, was signalized this week by the action of the Federal court at Seattle, in discharging Carl M. Johanson, receiver of the Merger Mines Co. Prior to his dismissal, an agreement was filed with the court, terminating all disputes between the Merger and the Jumbo Extension companies. This agreement includes that the Merger company admits that the Jumbo Extension company is the lawful owner of the Velvet Lode mining claim, now in its possession, and of all the minerals within the exterior boundaries thereof, extending downward vertically, and release and quit claim to said Jumbo Extension company any and all right therein. This agreement also constitutes a perpetual side-line agreement between the companies, and provides that either may use workings of the other when such use will not interfere with regular operations. The last named provision is merely a matter of form, as neither company is likely to have any use for workings of the other, but it is planned to make air connections between workings of the two mines on the 1017-ft. level in the near future.

It is estimated that the net production of the Jumbo Extension in July was approximately $60,000. The secretary, Ben Gill, states that returns from June shipments, still incomplete, indicate a production larger than estimated, and probably slightly over $55,000 net. A production of about $60,000 net monthly, will be made until the Velvet shaft is completed, when the output will be approximately doubled. The mine continues in excellent condition and stoping is now in progress from drifts east of raises 503-B and 503-C, in the big quartz fissure that penetrates the shale and below the contact ore-channel. It is estimated that the new orebody, exposed on the shale-contact and south of the 524-ft. drift, contains shipping ore worth $3,000,000. The mine contains a large tonnage of ore of lower grade, containing copper and silver, which will be treated profitably by the concentration-flotation process recently evolved here.

On the 1175-ft. level of the Merger, the drift following the shale-contact and driven from the Grizzly Bear shaft of the Consolidated, has progressed over 280 ft. Raises have been

driven at intervals, through 40 ft. of silicious material, marking the contact, to the overlying latite. The character of the quartz is more encouraging, as the drift progresses, and it is thought that the extension of the Jumbo orebody will be exposed soon. The manager, A. I. D'Arcy, has left by auto for a month's vacation in California. His assistant, William Sharp, is now in charge of the Merger, Atlanta, Sandstorm-Kendall, Kewanas, Booth, and Blue Bull properties, of which Mr. D'Arcy is manager. The special meeting of shareholders of the Merger company, August 4 at Seattle, was for the purpose of ratifying the agreement with the Booth company, increasing the capital stock from 5,000,000 to 6,000,000 shares, and authorizing the payment of 750,000 shares to the Booth company, in settlement of the apex claims of the latter.

Good results are reported in further opening the ore on the 1660-ft. intermediate level of the Atlanta, as well as at the newer discovery, 100 ft. farther north, and on the 1620-ft. level. A raise from the 1750-ft. level is being advanced to connect with the south drift on the 1660-ft. and to develop the ore between these levels. The drift at 1620 ft. will be extended to connect with the same raise. Shipping ore has been assaying from $32 to $41 per ton, and the manager reports the presence of ore of lower grade, varying from $8 to $20 per ton, in large quantity.

The main shaft of the Great Bend property has been cleared of water and debris, and development will now proceed on the 400-ft. level, where a drift and cross-cut had been extended and some rich ore exposed in a short raise several years ago, when the miners were driven out by water. The property has been equipped with an excellent surface plant, and with pumps of ample capacity. J. K. Turner is consulting engineer and Jack Campbell, a pioneer mining engineer of the district, is manager. Great Bend has shipped about $70,000 in high-grade ore in the past, and old assay records show that ore of good grade was found at several places.

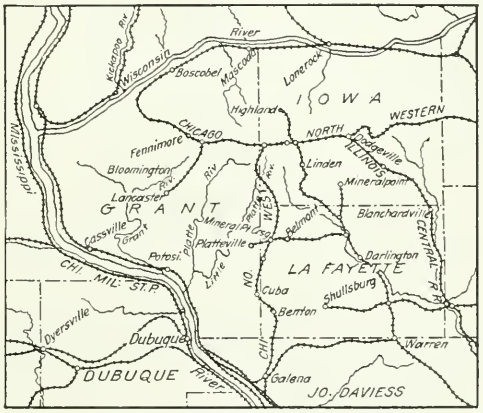
Work of the Silver Pick Consolidated is at an interesting stage. The west cross-cut on the 500-ft. level has penetrated the Phelan vein, and proves it to be 16 ft. wide, of low-grade quartz. Drifts are now being started north and south on this vein. The east cross-cut on the 700-ft. level has been in a broken formation, indicating heavy faulting, and is apparently nearing the main vein, explored to some extent on the 500-ft. level, and which is apparently the north extension of the Combination vein of the Goldfield Consolidated.

PLATTEVILLE, WISCONSIN

Situation of the Zinc Producers in July.—Malm Process.—Lead.—Pyrite and Sulphuric Acid.—Carbonate of Zinc.—District Yields.

July resulted in large and interesting developments in all branches of the zinc-lead mining industry of the upper Mississippi Valley districts. Continued high prices for metal and ore made its influence felt. While production showed no large increase, shipments were much better than usual. Buying was centred on the highest grades of zinc concentrate but the ban on inferior grades was lifted somewhat, and purchases were made during the latter part of the month down to 40% zinc-content. This did not help to diminish the reserve in the field, which at the close of the month aggregated 10,000 tons or more. Optimism as to prices prevailed, and not a siugle organization in the field relinqnished its efforts to maintain a maximum output. This feeling was extended in other directions, and the month's work was done nnder conditions that can be ascribed to boom periods. New capital became interested, especially in the southern districts where great strides are being made in the development of new land for zinc-mining purposes. Abandoned properties have been resurrected, and every available foot of ground has been secured by mining leases. Agents of local operating concerns, landowners, and lessees have been swarming in the hotel lobbies of Milwaukee, Chicago, St. Paul, and nearby cities, soliciting financial backing for various projects. Large profits are being made on account of low costs, which are down to including separator treatment, less than $15 per ton of concentrate. It is this high-grade separator product which is now in constant demand that is bringing from $95 to $110 per ton. No great recession in price was experienced during the month. The operators in the field prepared to refine low-grade ores have become aroused to the real needs of the region, and snbstantial gains were made in treatment capacity at all plants.

The Malm process of separation is attracting considerable attention. It is claimed to make a complete and separate recovery of all contents in ores, besides entirely eliminating the smelters. The general principles of the process are briefly as follows: the ore, properly dried and crushed, is fed into one end of a tube-mill, where it is subjected to the action of chlorine gas, being kept in contact with the gas long enough to chloridize from 40 to 70% of the metal-content. The ore is conveyed to a roasting-furnace, where the heat breaks up the iron chlorides and liberates chlorine free or as hydrochloric



ZINC DISTRICTS OF WISCONSIN.

acid, leaving the iron in an inert oxide condition. This acid unites with the sulphides forming chlorides of the metal-contents. The ore is passed to an agitator, solution is added and precipitation commenced. The various precipitates are separately collected in filter-presses, dried, melted, and cast into bars. Numerous tests have given extractions of over 90% of all the metals in an ore. The products obtained are in the most concentrated form possible for shipping to market. Great claims are made for the process. Leading mining men are interested, and a plant is proposed at a central point in the field to test the method.

Lead ore was in poor demand all the month; sales and shipments were very light. $60 per ton for 80% metal-content held throughout the month. The reserve at all points in the field gained considerably, as most of the lead secured in this region is obtained as by-product in the process of wet concentration, the heavier the output of zinc ore the greater the recovery of the lead. The close of the month found 2500 tons in bins. Miners were showing no desire to sell at prevailing figures.

The production of pyrite was confined to product secured at separating-plants. Fines were in good demand at $3.75 to $4 per ton of 50 units, and the ore cleared for reduction in sulphuric-acid works. The New Jersey Zinc Co. will restore its acid-plant at Mineral Point, shut down five years ago on account of damage-suits brought against the company for injuries worked to shrnbbery, trees, and lawns in the vicinity. A device has been patented which controls the fume. The

original plant represents an investment of $1,000,000, and gives employment to several hundred men. One 25-ton tank car of commercial sulphuric acid was shipped daily. More low-grade ore will now be in demand to supply the necessary material. Miners, especially low-grade producers, have taken new hope from the proposals.

Producers of carbonate of zinc received the highest prices ever known for this ore, the first days of the month recording $60 to $70 per ton 40% base zinc-content. Miners engaged in producing this ore are beginning to give up all hope of ever deriving any returns from their mines on account of the conditions of disposing of their product.

Deliveries of ore by districts were reported as follows:

Districts	Zinc Pounds	Lead Pounds	Pyrite Pounds
Benton	12,638,000	354,800	344,000
Hazel Green	4,944,000	289,000	.....
Galena	4,878,000	.....	.....
Cuba City	3,728,000	.....	2,449,220

DEADWOOD, SOUTH DAKOTA

Water-Rights Dispute.—North Homestake.—Homestake Improvements.—Wasp No. 2 Tungsten.—New Mill.—Echo.—Trojan Sampler.—Rattlesnake Jack and Mogul Mills.—Tungsten and Gold.

To the end of July, the rainfall in the Black Hills for the current year is over 28 in., the average annual precipitation at Deadwood being 20 in. Springs and gulches are seldom running at this time of the season, so there is an assured supply for the remainder of the year.

Opposition is developing against the diversion of waters of Elk and Bare Butte creeks, petition for which diversion J. T. Milliken has made through the regular channels, namely, the office of the state engineer of South Dakota. Mr. Milliken wants the water for milling and other purposes at the Oro Hondo mine. Those opposed to him in this matter include the owners of the Clover Leaf mine, at Roubaix, on Elk creek; farmers along both creeks, and the United States government, which is interested on account of using at Fort Meade, a supply secured from Bare Butte creek. A hearing will be held by the state engineer at which the contending parties will be heard. Mr. Milliken's diversion would be located near the head-waters of Elk creek. His contention is based on a state statute which permits water to be appropiated that has not been used for three years. Just what influence prior water-rights would have, which are located down the stream, is a question that has not yet been settled by rulings nor in court. For that reason considerable interest attaches to the proceedings now under way. Mr. Milliken has the good wishes of residents of the Black Hills, as the complete development of the Oro Hondo would mean the adding of a large producer to the present list, but it is apparent that these same residents are not willing to let him take their water. The Oro Hondo shaft is steadily being deepened; it is now 1650 ft. below the surface. Cross-cutting is under way in both directions on the 1500-ft. level.

Water has been removed from the underground workings of the North Homestake company, at Maitland, the small compressor placed on a new concrete foundation, and other incidental repairs and improvements made. It has not been announced whether lateral work or sinking will be done.

Construction work for the many improvements at the Homestake, at Lead, is being continued steadily. A big landmark was erected when No. 1 smokestack was recently completed at the new boiler-plant. This stack is 220 ft. high, constructed of sheet-steel on a massive foundation of reinforced concrete. Work has been started on the second stack, which will be similar to the other. The boiler-house roof having been completed, the tramway has been built over the coal-bunkers, and the chutes are being installed. Work of installing the boilers will soon commence. At the B. & M. shaft the head-frame is finished, also practically all work in erecting the great hoisting-engine. Part of the shaft-house has been completed. The air-compressor, which will supply air for operating the clutches, reversing-gear, and brakes on the hoist, is being installed, but not until the boiler-plant is ready to furnish steam for the hoist will the old compressor and boiler-room be torn out to make way for the immense new machine which will furnish air for some of the drills in the mine. The electric-plant building is completed, a portion of the machinery installed, and at the rear of it erection of the condensers has been started. Efforts are being made to complete all of the new work before cold weather.

As mentioned in the Press of July 17, tungsten ore is being extracted in small quantities at the Wasp No. 2 gold mine, at Flat Iron. Even though in small quantities, its gross value in the course of a month runs into thousands of dollars. The company is particularly fortunate to have found it at this particular time, as $9 per unit was realized for the last shipment. The material will average nearly 40% tungsten trioxide. It is probably wolframite, as analyses show it to contain both iron and manganese in considerable quantities. It also contains about $20 per ton in gold. The tungsten buyers do not pay for the gold-content. The usual dividend of 1c. per share was paid on July 15.

The newest mill to be added to the list of producers in the Black Hills is that of the Rattlesnake Jack, at Galena. It started on July 19. The plant is equipped with 10 stamps, Hardinge mill, Dorr classifier, and Trent cyanidation system. It is one of the most complete in the Hills, and reflects up-to-the-minute practice in all departments. C. B. Harris is manager.

Shaft work is progressing favorably at the Echo property at Maitland. From June 16 to July 19 the shaft was deepened 29 ft., notwithstanding trouble with the sinking-pump. Considering everything this was good work. Two shifts of miners are employed. The sinker is operated by compressed air.

Among the improvements that have been made at the Trojan mill, at Trojan, South Dakota, is a device by which an accurate sample of the mill-feed is procured each day. At the head of the conveyor that delivers the crushed ore to the mill-bin a slow-moving pulley has been installed; this actuates a sheet of steel that is interposed against the stream of ore at intervals of about 90 seconds, diverting the entire stream for about 2 seconds to a chute leading downward through the floor of the bin. By this means a sample comprising about 2% of the full mill-feed is secured. This sample may be diverted to either one of two sample-bins, which will hold 6 tons each, the maximum amount cut from a day's run of 230 to 250 tons of ore to the mill. From this bin, chutes lead direct to a small grizzly at the lower end of which is a Samson sample-crusher. The entire content of the bin is put through the grizzly and crusher, drops to the boot of a bucket-elevator, at the head of which the ore is divided in a chute, half going to the mill-bin, and the remainder to a third sample-bin. After the first sample-bin has been emptied, the grizzly opening is made smaller, the jaws of the crusher are set to give a finer product, and the contents of the third bin are put through a smaller mesh. During this operation the sample

is 'circulated' and continually cut down at the head of the elevator until it amounts to only 100 lb. It is then further reduced by shoveling over a split-sampler until its quantity is small enough for the assayer. The equipment in all details is well arranged and undoubtedly gives as nearly a correct sample as it is possible to secure under present conditions.

The mill is well arranged and many of its details are worthy of mention. One of the most noteworthy achievements learned on a recent visit was that an average of 230 tons was being crushed daily by one 7-ft. Trent Chilean mill through a screen of 0.021-in. opening. The ore is medium hard, and this duty for a single machine is probably a performance unequalled anywhere. The company is on a good profit-earning basis, and has several years' ore supply in sight.

The Rattlesnake Jack mill, near Galena, is working well. The plant includes 10 stamps, a Hardinge pebble-mill, Trent cyanide system, and Merrill precipitating-press. The daily tonnage is from 70 to 80 of hard ore.

Engineers representing W. Flynn and Senator George Oliver, of Pittsburg, are making a thorough examination of the McHugh and Gillmore properties, between Lead and Deadwood, and adjoining the Homestake. They are sampling the workings, and will do several thousand feet of diamond-drilling.

John R. Mitchell, of Denver, is investigating the Lexington Hill properties, which have been represented to him as containing an immense quantity of low-grade cyaniding ore.

Another De La Vergne oil-engine of 100-hp. capacity is almost installed in the Mogul mill, at Terry. This will increase the mill duty to about 200 tons per day. The new engine is of the same type and size as the old one, but is a later model, and contains some improvements. It will be used for driving the crusher, another Chilean mill, and some small machinery, including air-compressors, diaphragm-pumps, etc. The increase in tonnage at the plant will permit the handling of a lower-grade material, which occurs in large quantities in the stopes. Demands for handling custom ores have been numerous, so the management decided an increase in capacity was justified. In the past few weeks some of the old tailing from the Kildonan chlorination mill, at Pluma, has been shipped to the Mogul mill for cyanidation. As this material assayed over $6 per ton, it yielded a good profit.

Sixteen thousand dollars was recently received by the Wasp No. 2 Mining Co., operating at Flat Iron, for 40 tons of wolfram ore recently shipped to the Primos Chemical Co., Philadelphia. The shipment was hand-sorted from over 200 tons of ore. The reject is on the dump and in the bin, at the mine, in two grades as sorted, and will be marketed later. Production of the rich material continues. The ore now exposed is as good as it has been at any time in the past four months; it lies on top of and in quartzite, in a poorly-defined shoot 12 inches thick, and four to seven feet long. At the edges it is broken, and the wolframite spreads out in narrow seams. Immediately above the quartzite is a stratum of sandy shale a foot thick, and above this about an equal quantity of sandstone; next above is shale. The richest ore appears to be a replaced quartzite, although some of the purest of the wolframite occurs in a sandstone matrix. While this is not the first production of wolframite from this property, five tons having been shipped some years ago, it is the first important discovery made. It was found near the roof of a stope being excavated in the gold-bearing quartzite, which is cyanided, and an odd feature is that extraordinarily rich gold ore, sometimes assaying thousands of dollars per ton, is found in small quantities in the wall-rock of the ore-shoot. The wolframite itself assays $15 to $20 per ton in gold. The shipment yielded over 56% tungstic oxide, and the lower-grade ore on the dump will average 10%. The company's cyanide-plant continues to treat an average of 500 tons of gold ore per day, assaying about $2 per ton. Bumping-screens have replaced the stationary-screens long in use. The usual monthly dividend of 1c. per share was paid in July, and the August rate may be higher.

LEADVILLE, COLORADO

Dredging at Leadville.—Down Town Areas.—St. Louis Gold Ore.

The first dredge to operate in the Leadville district was launched on August 5, by the Empire Gold Dredging Co. Great interest was taken in the event. The company was incorporated here early in the spring, and immediately proceeded under the management of Robert E. Lafferty to purchase the large placer area along the Arkansas river and Box creek, known as the old Derry ranch, as mentioned in the Press at the time. The ground includes about 300 acres of the richest gravel in this region. It has been thoroughly tested, and averages 30c. gold per cubic yard. Complete title to the land and the water rights were obtained near the first of April. Machinery and supplies for construction of the boat began to arrive about the fifth, and actual work on the building was started on the tenth. Since then some 30 carloads of machinery have been delivered at the siding near the site, and a large force has been engaged assembling parts and constructing the hull. The boat is 107 ft. long with a 42-ft. beam built of the heaviest California timber.

The machinery is now being installed on the hull. Some of it is heavy. The large revolving-screen weighs 30,000 lb.; spuds 50,000 lb.; and the bucket ladder 108,600 lb. When the boat is complete it is expected to draw about 8 ft. of water. The dredge should affect the prosperity of the district. Mr. Lafferty is confident that the boat will operate for from 10 to 15 years on the ground that he now controls. There are many other smaller tracts of valuable ground in the district suitable for dredges. The boat should be at work early in October, and will operate steadily all the year.

The draining of the Down Town basin of the Leadville district is progressing steadily, and in the most satisfactory manner. The pumps will be described in detail in the next issue of the Press, accompanied by a plan of the shaft and chart of pump efficiency.

Ex-governor Jesse F. McDonald, who is manager of the company and directly in charge of the work, is highly pleased with the progress and states that actual mining in the drained areas will be under way by the first of 1916. The opening of the Down Town basin to mining is expected to result in one of the largest and richest ore-producing areas. The ground controlled by the company is roughly estimated to be three miles square, and is known to be rich in lead, zinc, silver, iron, and manganese. The most extensive operations that have ever been carried on here are planned by the Down Town company.

The richest property that has been developed in the Leadville district this year is the St. Louis adit now being operated under the control of the Third Venture Mining Co. W. A. Palmer, of Boston, is president and is in charge of the work. The largest shoot of high-grade gold ore that has been opened here since that of the Little Jonny on Breece hill has been opened in the St. Louis adit. The adit adjoins the Jonny and other claims of the Ibex Mining Co. on the north slope of Breece hill, and it is the extension of one of the rich shoots from the former that is now producing the ore in the St. Louis. Mass gold, from several inches in diameter to that of a small pea is being taken from the vein at the rate of about $2000 per day. Mr. Palmer states that the orebody is continuous, and in places extremely wide. He is confident that the shoot as now developed will afford mining at the present rate for a number of years. He has a seven years' lease on the ground. In addition to this rich ore, several large bodies of rich shipping ore have been opened in the property, and a large tonnage of this material is being extracted. The present operators of the St. Louis have been working for a number of years without success, and the continuation of developments have often been despaired of by Mr. Palmer, because of the heavy expense. He, however, had confidence in the property, and is now making excellent profits.

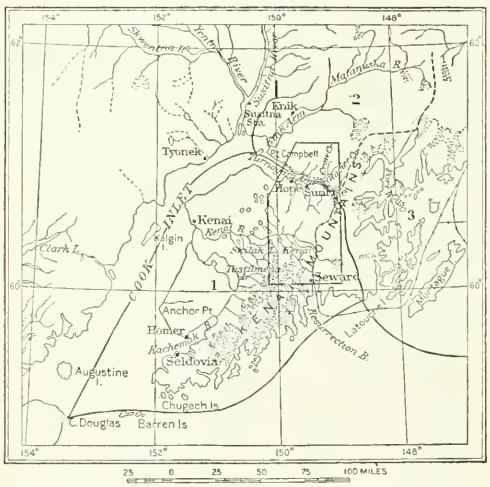
THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

On July 30 the Workmen's Compensation Act became effective. The provisions are liberal, the largest amount being $6000.

The geology and mineral resources of Kenai peninsula are described in Bulletin 587 of the U. S. Geological Survey by G. C. Martin, B. L. Johnson, and U. S. Grant. With maps it covers 243 pages. The area, 9400 sq. miles, lies between Prince William sound and Cook inlet, and is almost separated from the rest of the continent by the waters of Passage canal or Portage bay, and of Turnagain arm. There are two distinctly dissimilar districts, the mountains and the lowlands. Seward is the largest town. Alfred H. Brooks states that the peninsula contains auriferous lode-bearing areas of some promise,



MAP SHOWING THE RELATION OF THE AREA DESCRIBED IN THIS REPORT TO THE KENAI AND KNIK RECORDING DISTRICTS.

1, Kenai recording district; 2, Knik recording district; 3, Valdez recording district.

though deep mining has so far been done on only a small scale. Gold-bearing gravels are widely distributed in the northeast part and for nearly 20 years have been worked in a small way. The future of placer mining here depends on large-scale operations on low-grade gravel. Large deposits of lignitic coal occur on the Cook Inlet side. Hydro-electric power is possible. Timber is sufficient for local use. There is good fishing and hunting. Work done and being done is given in detail.

Fairbanks

The strike of placer workers ended here on July 24. The trouble arose over hours and pay.

ARIZONA

Mohave County

The United Eastern mine has made its first shipment, consisting of 35 tons of $30 ore. This went to the Gold Road mill. It is intended to mine about 1000 tons per month. The ore comes from development at 460 and 565 ft., and future extraction will be from these levels. The west drift at 460 ft. has a length of 190 ft., and the east drift at 565 ft. is 210 ft., making a total of 400 ft. in the ore-shoot. The face of each drift is filled with ore, and there are no indications of its getting narrower. On the dump is about 2000 tons of good ore.

Pinal County

The Ray Consolidated Copper Co. reports as follows for the second quarter of 1915:

Results of operations	Second quarter	First quarter
Mine development, feet	10,769	.....
Cost of mining and crushing, cents per ton	60.959	.....
Ore treated, tons	679,004	656,672
Average metal-content, per cent	1.677	1.667
Copper output, pounds	14,524,380	14,463,213
Copper from ore shipped direct, pounds	277,851	.....
Cost of treatment, cents per ton	44.53	48.95
Cost per pound, cents	9.057	.....
Net profit	$1,340,886	$741,539
Dividend paid	547,035	.....
Surplus	$793,851	$741,539

Yavapai County

The Western Investment Co. is considering the driving of a long development, drainage, and transportation adit to develop all the veins between the Bradshaw Mountain railway, two miles below Crown King, and a point near Hooper, at depths from 1000 to 2200 ft.——The Arkansas and Arizona Mining Co., operating at Jerome, is being re-financed. The mine is opened to 1648 ft., with good equipment.——Six miles from Prescott the Arizona Mine Supply Co. is to sink to 500 ft.——A mill is being erected at the Saratoga mine.——Cinnabar deposits in Copper Basin are to be developed.

CALIFORNIA

Amador County

It is reported that the Kennedy company has purchased the Zeila mine at Jackson for about $50,000. This property is said to contain a large quantity of ore, requiring modern equipment for profitable extraction.——The Bunker Hill output in July was $35,000 of which $13,000 was profit. The dividend absorbed $5000. The lower levels are opening well.

Butte County

A representative of the Luther Burbank Co. is at Oroville investigating the suitability of dredged areas for growing the firm's spineless cactus, used for feeding stock. Some of J. H. Leggett's land will be tried first.

Eldorado County

The Georgia Slide claims near Georgetown are being examined by M. L. Hurley of New York, and a lease has been secured by H. K. Montgomery until September.——The Rising Hope gravel mine has made its first shipment of gold after five years' work. G. W. Engelhardt is manager.

Inyo County

A report on the Cerro Gordo mine near Keeler has been made by Edward S. Spring. The property is in a comparatively inaccessible position, making haulage charges heavy. An aerial tramway 29,118 ft. long, costing about $50,000, from the mine ore-bins to those at the railroad at Keeler, is nearly

finished. L. D. Gordon is the present lessee, his lease expiring on September 18, 1915. The main vertical shaft is down 900 ft., with an incline winze 250 ft. below that depth. Faulting has been of frequent occurrence. The best ore occurs chiefly in limestone. At present only zinc ore is being extracted. Silver-lead ore also occurs. The Cerro Gordo Mines Co. also controls the adjacent Newsboy claims. Over 50,000 tons of slag from former smelting operations is a large asset.

Nevada County

At the Cassidy mine, adjoining the Empire, nine miners under W. P. Martin, averaged 11 ft. per day in hard ground for the past four weeks.

Relatives of two of the men killed in the Columbia mine near Washington some time ago are to receive a total of $4150 each. The other case has not been settled yet.——Hawke Bros. are constructing a small dredge on Deer creek, near Nevada City.

Placer County

The Federal Drift Co. is sinking and driving under the town of Dutch Flat, in charge of W. T. Watson. The district is showing increased activity.——The Rossier silver-lead mine near Colfax is being examined.——Thirty-five men are working at the Ralston mine.

Plumas County

The State Railroad Commission has granted permission to the Great Western Power Co., whose plant is on the Feather river, to construct a transmissiou-line to the Engels copper mine and mill.

San Diego County

In the Chamber of Mines and Oil, Los Angeles, *Mining and Oil Bulletin* for July, tube-mill pebbles from this county are discussed by E. H. Schiek, who states that the pebbles gathered on the beach there are of good quality.

Sierra County

Speciman ore, worth about $10,000, was taken out of the Eldorado mine on Kanaka creek, below Alleghany, last week by Fessler Bros. and Armstrong Bros.——A good development is reported from the Twenty-one mine, adjoining the Tightner. ——At the Monarch and Cleveland mines, near Sierra City, 75 men are employed. Considerable work is under way. Ten stamps are dropping at the latter.

Tuolumne County

(Special Correspondence.)—At the old Santa Ysabel mine, just south of Jamestown, there has been a good deal of activity in the last two months. Twelve men are now working in the lease, and twelve are on the pay-roll of the Nyman Consolidated Mines Co. About 20 tons of good milling ore is being extracted from the lease each shift. The mill-bins are filled from the rich Mascot ores now being drawn from the 200 and 250-ft. levels from the main three-compartment shaft. Fifteen stamps are dropping and another five will be added as soon as the ore reserves are equal to 20-stamp capacity in the 40-stamp mill. About 500 tons are now in reserve in the Mascot stopes, and three machines are increasing this amount. Last year the Mascot vein was found on the 400-ft. level, showing 12 in. of excellent ore. A raise will soon be started on this shoot to connect with the 250-ft. level, and systematic extraction started. The property is fully equipped with 40 stamps, a 750-cu. ft. air-compressor, a 2000-ft. steam hoist, a 400-kw. substation for the operation of all equipment except the hoist. The work at the mines is under the direction of C. E. Shafer, who was formerly in charge of the Harvard mines.

Jamestown, July 29.

COLORADO

Clear Creek County

Cyanidation has been abandoned at the Hudson mill at Idaho Springs, amalgamation, concentration, and flotation now giving excellent results. S. P. Warren is in charge.

Eagle County

The Iron Mask, Rock Point, and Chief mines at Red Cliff have beeu purchased by the Empire Zinc Co. at a high price. The Eagle mill which is treating 120 tons daily, is included in the sale.——It is rumored that the American Zinc Co. is negotiating for zinc properties near Red Cliff.

Gilpin County

According to Robert Sayre, of Black Hawk, the Lake mine, which is operated through the Big Five tunnel at Idaho Springs, produced 16,507 tons of ore which yielded a net return from the smelters of $122,629. The mine is developing well, good ore being opened at 2300 ft. depth. Mosher and others have most of the miue on lease.——Lessees at the Gilpin Eureka are making good profits.

Gunnison County

Twenty four-horse teams are hauling iron-zinc ore from the Doctor mine 19 miles to the railway. A large lode has been opened.——The Denver City people are still unwatering their property.——The Brant company is installing machinery.

Lake County (Leadville)

At the Down-Town property the station at 470 ft. in the Penrose shaft is nearly complete. The Valley adit is in 1200 ft. into Prospect mountain. The ground is heavy, and timbering is difficult.——A large tonnage of ore continues to be shipped from the Ibex.——Lessees are re-opening the old Bartlett mine on Sugar Loaf.——Mining in the Lackawanna area is increasing.

Park County

Rich gold ore (about $100 per ton) that had been extracted from the London mine during last winter is now being shipped to smelters. Cripple Creek and Denver people are investigating properties nearby.

San Juan County

The Wilfley mill has started treating tailing from the lake near the Silver Lake plant. Flotation is part of the process. ——The Frisco mill is working again.——Development continues at the Golden Fleece, Syracuse, and several properties near Animas Forks.

IDAHO

Bonner County

Fire of unknown origin completely destroyed the mill of the Idaho-Continental mine, 26 miles from Porthill, on July 30, entailing a loss of $50,000. The plant was insured for $20,000. One hundred men were employed at the property. The president, A. Klockman, states that it will be re-built.

Shoshone County (Coeur d'Alene)

Dividends paid by Coeur d'Alene mines during July amounted to $1,124,490; the total this year to date is $2,849,098, exclusive of profits paid to owners of the Hercules mine. July payments were as follows: Interstate-Callahan, $575,000; Stewart, $309,-590; Bunker Hill & Sullivan, $81,750; Caledonia, $78,150; Hecla, $20,000, and Success, $60,000. Dividends for August are expected to greatly exceed those for auy previous month in the history of the region. The special declaration of Interstate-Callahan of $920,000 is expected to be followed by announcement of a liberal payment by several other dividend payers. The Hecla company announces that it will pay 7c. per share, or $70,000, monthly. Net earnings of the Interstate-Callahan in June were $675,000. Shipments of ore and concentrate amounted to 5400 tons.

On August 20 the Success company will pay 8c. per share, equal to $120,000. This makes $285,000 for the year, and $630,-000 to date. Many improvements are being made to the property.

It is rumored, apparently with some foundation, that the Hercules Mining Co. and the A. S. & R. Co. have agreed as to the smelting contract. The Hercules is to pay $16 per ton for freight and treatment, and the settlement rate is to be 90%

of the full New York price for 90% of the lead-content of the ore. As a further concession, it is said, the Smelting company has promised to keep Harry L. Day, one of the Hercules owners, as president of the Federal Mining Co., which is controlled by the Smelting company.

MICHIGAN

The Copper Country

In the first half of 1915 the Mohawk produced 7,410,393 lb. of copper. The average yield is about 18 lb. per ton of ore. This output is far ahead of previous periods. Costs were the lowest on record.——On July 31 the Wolverine and Mohawk companies paid their 1200 employees a 5% bonus.——Owing to a minor accident at the Allouez, the output in July was not quite 1,000,000 lb.——The daily ore production of the Calumet & Hecla is now over 11,000 tons.——During the financial year ended June 30, 1915, the Wolverine produced 7,350,866 lb. copper at about 8.5c. per pound, from 297,614 tons of ore. The June output was 637,346 lb.——Financial results are as follows:

	1915.	1914.
Revenue	$929,192	$484,081
Profit	318,201	81,075
Dividends	360,000	.....
Surplus	787,310	829,109

The *Daily Mining Gazette* estimates the copper output of the district in July as follows:

Mine.	Pounds.	Mine.	Pounds.
Calumet & Hecla	8,050,000	Mohawk	1,300,000
Quincy	2,000,000	Franklin	270,000
Copper Range	5,400,000	Centennial	280,000
Winona	200,000	Allouez	850,000
White Pine	450,000	Mass	500,000
Houghton	70,000	Superior	360,000
Tamarack	450,000	Hancock	175,000
Osceola	1,900,000	LaSalle	125,000
Ahmeek	2,300,000	Victoria	260,000
Wolverine	700,000		

MISSOURI

Jasper County

Production of the Missouri-Kansas-Oklahoma region during the last week of July was as follows: blende, 4885 tons; calamine, 328 tons; and lead, 573 tons. The average value was $90.91, $46.22, and $58.54 per ton, respectively, the total value being $492,809. For 31 weeks the total is $13,552,401, blende, accounting for $11,699,861.

St. Francois County

It is reported that in July the St. Joseph Lead Co.'s earnings were over $500,000. The large export contracts are resulting in big profits.

MONTANA

Silverbow County

During the second quarter of 1915 the Davis-Daly Copper Co. did 1697 ft. of work at 1400, 1700, 1900, and 2500 ft. Encouraging results were obtained at the lowest level. Low-grade ore from 1700 ft. has been mined at a profit. The output was 1422 tons of ore assaying 3.7% copper, and 6.4 oz. silver. The cash balance is $56,999. Assessments are coming in slowly.

Net earnings of the Butte-Ballaklava in July were about $37,000. The daily output is 250 tons of ore, containing 3.4% copper.

NEVADA

Churchill County

In the second quarter of 1915 the Nevada Hills company treated 16,410 tons of ore averaging $5.94 per ton. The tailing loss was 97c. per ton. The net profit was $17,105. Assets total $278,145.

Esmeralda County

The Florence mine produced 430 tons of $18 ore in July. This was extracted from the 'new' vein at 250 ft. north of the shaft of the old Florence Con. lease area. Owing to a fire at the Campbell & Kelly foundry at Tonopah, the new head-frame and equipment will be delayed about a month.

Humboldt County

The Willard district is proving to be more persistent, and prospects are good. A representative of an ore-treatment concern considers that there are large quantities of good milling ore. The Honey Bee adit is in 125 ft., cutting $25 to $40 ore. The Oddie-Malley-Cole lease cross-cut at 50 ft. depth is in good ore. Conditions at the Healey-Mayer-Borland, Sheepherder's Dream, Excelsior, Big Thing, Ruth, Finland, and the Fords are encouraging.

The Friedman adit, to cut the veins in Rochester hill at 1200 ft. depth, is being driven 12 ft. in two shifts. The adit is in 430 feet.

The Buckskin National company has purchased a hoist and compressor. Drifts from No. 2 level have opened the vein for over 1000 ft. in good ore. F. F. Bell is superintendent.

Lincoln County

Foundations for the 50-ton mill for the Yuba Leasing company are being prepared. The plant is expected to start by September 15.——Plans have been prepared for the new mill of the Amalgamated Pioche company. A Colorado smelting company will take the product. The output of ore last week was 300 tons.

Lyon County

The new 250-ton leaching-plant for the Nevada Douglas company is nearly complete. Work was started in September 1914. The mine is estimated to contain 550,000 tons of 3% copper ore. Recent development has added 30,000 tons averaging 5%.

Mineral County

(Special Correspondence.)—Active work continues at Rand, 15 miles east of Walker lake. At the Queen Regent Merger, part of the property has been leased. Shortly after this was let, 9 ft. of ore was cut, 7 ft. suitable for milling, the remainder for shipment. One carload assayed $58 per ton. The Golden Pen is showing rich ore. One lot was worth over $100, another $250, and another $400 per ton, while specimen ore is sent out by express. Higher up the hill a fine vein is being opened by an adit. The owners want $125,000 cash for the property.

Rand, August 7.

A carload of rich ore has been shipped by W. S. McRacken, T. W. Kenyon, and W. A. Woodruff from the Eagle mine. The shipment, which went to the Selby smelter, averaged 4.35 oz. gold and 2.76 oz. silver per ton. The Eagle is an old mine, 300 ft. deep, developed by an adit only, and recently re-opened.

It is reported that rich gold-silver ore has been discovered 25 miles east of Mina. Claim-jumpers have been busy.

Nye County

Six companies and several lessees at Tonopah last week produced 10,722 tons of ore worth $218,956.——At the old workings of the Midway 10 sets of lessees are producing from $25 to $100 ore.——Lessees at the Montana shipped 49 tons.——The Belmont dispatched 176,284 oz. bullion and 42 tons of concentrate from both mills, valued at $133,000.——The Jim Butler is developing on five levels each at the Desert Queen and Wandering Boy.——The West End shipped 70,256 oz. bullion.——At 540 ft. on the MacNamara vein in the Silver Top claim of the Tonopah company there is 10 to 12 ft. of mill ore. $40,000 of silver was sent away last week.——The Extension shipped 103,350 oz. bullion and 27 tons of concentrate, worth $68,500. ——Development continues at the Mizpah Extension, Halifax, North Star, Rescue-Eula, Buckeye-Belmont, Bonanza, Umatilla, Monarch Pittsburg, and Cash Boy.

NEW MEXICO

Grant County

The Chino Copper Co. reports as follows for the second quarter of 1915:

Results of operations.	Second quarter.	First quarter.
Material moved, cubic yards	1,208,360	834,158
Ore treated, tons	592,200	406,000
Average metal-content, per cent	2.38	2.19
Extraction, per cent	65.34	66.12
Copper output, pounds	18,455,502	11,732,508
Cost per pound of copper, cents	6.10	6.38
Net profit	$2,006,548	$890,638
Dividends paid	652,455	434,970
Surplus	$1,354,093	$455,668

The cost was the lowest since operations started.

UTAH

Juab County

According to the semi-annual report of the general manager of the Chief Consolidated at Tintic, Walter Fitch, development totaled 2629 ft. Ore shipments amounted to 11,865 tons worth $21.78 per ton. Charges were $10.65 per ton, and total profit $47,020. The year started with a balance of $115,713, and at July 1 there was $211,954 on hand.

The Tintic district shipped 165 cars of ore last week. Some encouraging work is being done at the Grand Central, Gold Chain, War Eagle, Yankee, and some claims in west Tintic.

Piute County

It is expected that the Mineral Products Co.'s plant at Marysvale will start in September. Only potash will be recovered from the alunite.

Salt Lake County

The Utah Copper Co. reports as follows for the second quarter of 1915:

Results of operations.	Second quarter.	First quarter.
Overburden removed, cubic yards	1,548,132	1,143,596
Ore treated, tons	2,215,159	1,396,341
Average metal-content, per cent	1.42	1.42
Extraction, per cent	64.85	....
Copper output, pounds	40,799,825	26,415,995
Cost per pound, cents	7.49	8.19
Net profit from production	$3,680,249	$1,691,728
Income from other companies, etc	732,050	475,688
Total profit	$4,412,299	$2,167,416
Dividends paid	1,624,490	1,218,367
Surplus	$2,787,809	$949,049

The Bingham & Garfield railway carried an average of 16,798 tons of ore per day, and 29.21 tons of other freight.

In the Journal of the Western Society of Engineers of Chicago, for June, the Bingham and Garfield railway, a short road with some unusual features, is described by H. C. Goodrich. The road is 25.93 miles long from the Utah Copper mine to the mills near Great Salt Lake, including long bridges and tunnels. Including sidings, etc., the total track was 102.08 miles. The rolling-stock consists of Mallet compound locomotives, switching engines, ore-cars, concentrate-cars, general cars, passenger-cars, wrecking-crane, etc. The greatest tonnage of ore handled in a day was 26,730 tons, also commercial freight and passengers. Forty cars of 56-ton capacity make up a train. The difference in elevation of the terminals is 1874 feet.

The Cardiff mine, in Big Cottonwood, is shipping over 100 tons of ore daily. Ninety-five men are employed.——The Alta Tunnel & Transportation Co. has arranged to sell the water flowing from its adit to the municipality of Salt Lake City. The present quantity is about 647,000 gal. per day. The adit is in 1400 ft., or about one-third.——The Alta Tiger company has purchased an interest in the Highland Chief ground in Little Cottonwood, and will be able to gain 500 ft. in opening its property.

Summit County

A 50 to 75-ton capacity Callow flotation-plant is to be installed at the Daly-Judge mill at Park City. This will save the zinc and lead being lost in the slime, and will result in an additional recovery of $50,000 per year. After leaving the mill the slime will be filter-pressed, then pass to a Dorr thickener and the flotation cells. The company is making good profits.

The Snake Creek tunnel was advanced 368 ft. in July, making a total of 12,000 ft. It should be finished, 14,000 ft., early in 1916.

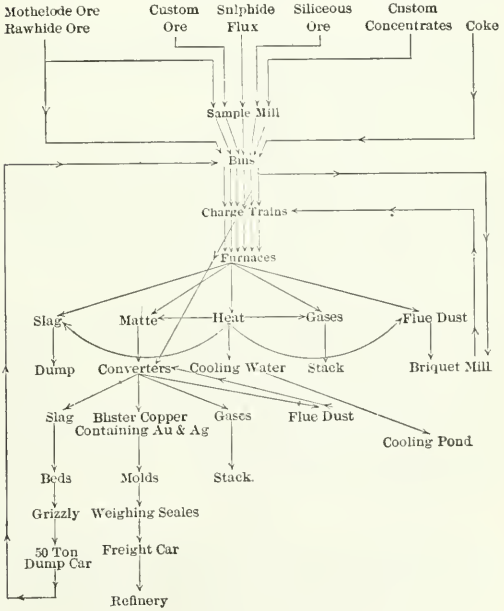
CANADA

British Columbia

At Grand Forks the Granby company has eight furnaces in blast. The output of copper for five months of 1915 was 6,057,249 lb. at Grand Forks, and 7,455,407 lb. at Anyox.

The Slocan district is more active than ever before, new mines being opened, and those idle for years being re-worked.

The high price of copper enables the British Columbia Copper



FLOW-SHEET OF B. C. COPPER CO.'S SMELTER AT GREENWOOD.

Co. to treat its low-grade ore profitably. The smelter at Greenwood has a capacity of 2000 tons per day. One furnace is now in blast.

The Silver Hoard Mining Co. is to erect a 50-ton mill using concentration by water and flotation.

Ontario

(Special Correspondence.)—It is reported that a new townsite is being planned at the gold camp of Sesekinika, 10 miles north of Swastika on the T. & N. O. railroad. The geological formation and the ores differ from the Porcupine area. The formation is generally andesite and diorite, while most of the

ores contain tellurium. The veins are narrow, but rich. Directors of the Dome are to consider the matter of declaring the initial dividend of the company. This is expected to be 5% quarterly. The estimated production for July is $130,000. ——It is expected that diamond-drilling will soon commence at the Preston East Dome which adjoins the Big Dome.—— The Buffalo company of Cobalt has been sampling the Teck-Hughes at Kirkland lake, on a basis of actual purchase of the property.——The rich ore of the Vipond recently cut between the 300 and 400-ft. levels is reported to be about $160 per ton. ——The annual report of the McIntyre shows the estimated ore reserves on March 15 to be 93,836 tons, worth $7.89 per ton, and broken ore in stopes 15,857 tons, worth $7.14 per ton. ——Efforts are being made to commence work at the West Dome in October.——The Ontario government last year sent a representative through the mining districts of the province in search of radio-active minerals. He was unsuccessful. Some of the ores of the Kirkland Lake and Goodfish districts are fonnd to be slightly radio-active, but not yet of commercial value.

It is reported that the Seneca Superior company at Cobalt has obtained a lease on the Gould Consolidated which adjoins it.——The old Wright mine on Lake Temiskaming may be worked again. This is probably the oldest silver mine in Canada, records and maps of the property dating back some 300 years. The ores contain galena.

Timmins, July 26.

YUKON

On July 23, No. 2 dredge of the Canadian Klondyke Co., which was being overhauled, resting on piles, suddenly slipped into the pond, killing one and injuring three others. This boat capsized at the end of last season.

MEXICO

American mine operators in northern Mexico interviewed Villa on August 11 regarding the conditions under which they are working. He wants all payments to his department in gold.

Exports of crude oil from Tampico to the United States during June totaled 864,208 bbl., against 684,824 bbl. in May.

CHIHUAHUA

(Special Correspondence.)—The Concheno Mining Co., controlled by Corrigan, McKinney & Co. of Cleveland, Ohio, has started its 60-stamp mill and cyanide-plant at Concheño Distrito Rayon. The equipment includes concentrators, sand-leaching vats, tube-mill, continuous agitation of slime, Butters filters, zinc-boxes, three 300-kw. generators driven by high-speed Ball engines, steam and electric hoist and compressor, also a turbine auxiliary. H. W. Edmondson is general superintendent, and Donald B. Gillies general manager.

Chihuahua, July 15.

SONORA

The Moctezuma mine and mill at Nacozari resumed work last week, after nearly a month's shut-down. Bridges on the railroad have been temporarily repaired, and trains of coal, oil, food, and other supplies have been received. Several hundred cars of copper concentrate awaits shipment to the Copper Queen smelter at Douglas.

KOREA

The Seoul Mining Co., operating the Suan concession in Whang Hai province, reports the following results for July at the Suan mill:

Ore treated, tons	6270
Mill working days	26½
Recovery, bullion	$45,785
Recovery, concentrates	$30,680
Total	$76,465
Operating expenses	$27,500
Net earnings	$48,965

PERSONAL

H. H. WEBB is at Santa Barbara.

ROBERT B. TODD was in Tonopah last week.

C. S. HERZIG was at Salt Lake City last week.

F. E. MARCY was here on August 10 from Salt Lake City.

P. T. BRUHL has arrived here from Collahuasi, in Chile.

JOHN W. MERCER left San Francisco for New York on August 12.

ROBERT VAUGHAN and W. D. ROGERS are returning to Cinco Minas, in Jalisco.

H. S. DENNY is in charge of the reconstruction of a high explosive factory in Wales.

GELASIO CAETANI has obtained a commission in the Aviation Corps of the Italian army.

FRANK H. PROBERT announces his change of address to the Hobart building, San Francisco.

PHILIP R. HUDSON and C. FIELD, both of the Guanajuato Development Co., were in San Francisco this week.

CHARLES E. LOCKE, Professor of Mining in the Massachusetts Institute of Technology, is leaving San Francisco today.

ROBERT S. LEWIS, Associate Professor of Mining in the University of Utah is at his home near Palo Alto, California.

ANDREW C. LAWSON, Professor of Geology, has been appointed dean of the College of Mining in the University of California.

F. F. HEYDENFELDT, superintendent of the Tonopah Mining Co.'s plant at Millers, has been spending a month in California.

CHARLES W. NEWTON, superintendent of the Con. Interstate-Callahan Mining Co. of Wallace, Idaho, spent several days in Butte recently.

FRANK MANSON, manager of the Western Ore Purchasing Co., was recently elected a director of the Goldfield Consolidated Mines Company.

WALTER SCOTT WEEKS, recently instructor in Harvard University, has been appointed Associate Professor of Mining in the University of California.

CHARLES E. VAN BARNEVELD, at present chief of the Department of Mines and Metallurgy at the Exposition, has been appointed Acting Professor of Mining in the University of California.

W. H. BLACKBURN, general manager of the Tonopah Mining Co., and J. G. KIRCHEN of the Tonopah Extension, were at Reno last week attending a meeting of the Nevada Mine Operators Association.

MORTON WEBBER, of New York, who obtained a commission in the Royal Field Artillery after the outbreak of war, was recently wounded in France. He has now recovered and has joined the British Expeditionary Force at the Dardanelles.

Schools and Societies

The NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES opens at New York on September 20.

The Seattle Association of Members of the AMERICAN SOCIETY OF CIVIL ENGINEERS met on July 26.

A new mining building to cost $215,000 has been given to the MASSACHUSETTS INSTITUTE OF TECHNOLOGY by several of its graduates.

The UNIVERSITY OF NEVADA at Reno, has issued its catalogue for 1914-1915, including announcements for 1915-1916. The publication covers 238 pages. The new year commences on September 1. Full details are given regarding admission, courses, and degrees.

The MICHIGAN COLLEGE OF MINES has issued its year book for 1914-1915, with announcement of courses for 1915-1916. It consists of 116 pages, and five tables showing time devoted to subjects, and three good maps of the region.

THE MARKET PLACE

Weekly Summary of Metal Prices and Notes on the Markets.

Metal Prices

San Francisco, August 12.

Antimony	35 —35¾
Electrolytic copper	20½—20¾

Quicksilver (per flask)	$95
Spelter	23 —23¼
Tin	39
Zinc-dust, 100-kg. zinc-lined cases	No quote

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, August 12.—Copper is weak; the only market in lead is at concessions; spelter has practically no market.

COPPER

Prices of electrolytic in New York, in cents per pound.

Exports of copper during the week ended July 14 totaled 11,352,552 lb., worth $2,181,114. Of this, France got 7,492,788; Russia, 1,905,316; England, 1,308,704; Australia 263,621; Italy, 187,556; and Holland, 113,402 lb. Imports of all kinds totaled 2,861,770 lb., valued at $430,064. Canada sent 2,469,970 lb., and Japan 391,022 pounds.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.		Average week ending	
Aug. 5	47.00	June 30	48.40

On August 7 about 270,000 oz. left San Francisco for China. Exports of silver from this port in July were worth $1,097,200, or, say, 2,250,000 oz. In the last week of July Cobalt mines dispatched 527,442 oz. The total from these for seven months is 5,068,043 oz. London will store bullion and make advances on it; while American smelters will take all they can get at New York rates, and settle in full. Exports from London to the Orient for the period to July 21 were £1,457,000 less, say, 15,000,000 oz., than in the same time of last year. London stocks are about 20,000,000 oz. The dominant factor of prices in London is the restricted amount of selling from America, which offsets the sluggish disposition of buyers. India and China have operated little. The main support comes from the Continent.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

June	30.72	40.26	Dec.	33.60	....

On August 11 tin was firm at 34 87 to 35.37 cents. The Vulcan Detinning Co. reports that its sales for the half-year totaled $369,695, and net profit, $41,715. In the second quarter sales were $34,000 less than in that period of 1914.

ANTIMONY

Demand is quiet, but Chinese spot is being offered freely. Chinese and Japanese grades still continue to be quoted at 35.25 to 36.25c., while special brands are nominal at 44 to 46 cents.

The Nevada Consolidated reports as follows for the second quarter of 1915, compared with the first quarter:

Overburden moved, cubic yards	754,649	.....
Ore treated, tons	849,155	564,834
Average copper-content, per cent	1 40	1.49
Metal produced, pounds	15,106,920	10,815,681
Profit	$1,364,093	$615,818
Dividend	749,796	749,796
Surplus	$614,297	.....

Eastern Metal Market

New York, August 6.

Prices of all metals in this market are on the down grade, with the exception of copper. While the quotation for electrolytic has remained steady at 18.25c., considerable metal has been offered by second-hands at a lower figure. None of the plants in this vicinity making ammunition are having any trouble with their machinist employees, although there are a number of rumors that one such plant and two who have subcontracts will be closed shortly. One manufacturer of machine-tools required by projectile-factories has a strike bothering him; the idea of the labor unions being to cripple the new plants that are entering the war-material field by cutting off their source of machinery supplies.

After being in a rut for months, pig-iron has started in the past week on what promises to be an important movement. Prices in all districts have advanced, and the sudden appearance of inquiry from many sources indicates an effort on the part of consumers to forestall a long-delayed rise. Pig-iron output is crowding close up to high-record figures on account of the demand for steel. The July production was 2,563,420 tons, or 82,691 tons per day, against 2,380,827 tons in June, or 79,361 tons per day. The steel companies are now close to their maximum pig-iron capacity. They made 62,895 tons daily in July, or 3900 tons more than in June. Production is now at the rate of 32,000,000 tons per year, against 18,000,000 tons on January 1. Rolling-billets are now quoted at $30 and higher in eastern Pennsylvania. This makes this class of semi-finished steel higher than some finished products.

ZINC

Prices have declined all the week, but the bottom does not seem to have been reached as yet. There is no demand for the metal, and with continued production at a high rate, further reductions in the price are not improbable. Dealers are anxious to dispose of their stocks, but very little has been sold for the last half, although the price for fourth-quarter delivery is 15 to 16c. At present the market is lower than it was after the reaction following the high June price of 26½c. Spot metal is difficult to obtain. Brass-mill special has declined, and is now quoted all the way from 18 up to 23c., compared with 30c. last week. Prices, while entirely nominal, have receded from 18.12c. a week ago, to 17.25c. yesterday, when the price fell to 16.50c. The exports for July which were the lowest since last August and about half those for June, amounted to only 4483 tons. For August only 200 tons has been sent abroad up to and including August the 5th.

COPPER

In spite of a market that has been dull for almost a week, producers have, nevertheless, been able to keep the price of electrolytic steady at 18.25c. While there has been considerable talk of impending transactions, it has not gone any further. There is no business, and consumers appear to be waiting for a further decline in prices, although the producers look forward to a revival of demand from domestic interests working on war business. For that reason they are not disposed to lower the 18.25c. quotation, but consumers appear to be well covered. Second-hands are reported as offering unlimited quantities at 18c., consequently there is little prospect that prices will be sustained. About all the business that has been done in the past three weeks has been limited to a few small sales. Russian and Italian munition contracts calling for 50,000 tons of copper are reported in the daily papers as being closed, but this cannot be confirmed. The quotation on Lake copper is nominally 21c. There has been no business to test the firmness of this price, but sellers are generally reported to be willing to meet buyers. The exports for the month of July were 17,308 tons, or about half those of July, 1914. The exports for the first five days of August amounted to 346 tons.

The following table shows the copper exports from Atlantic ports during July in gross tons:

Destination.		Destination.	
United Kingdom	3,865	Norway and Sweden	333
France	6,000	Russia	2,950
Holland	336	China and Japan	....
Italy	3,398	Sundries	376
Denmark	50		
		Total	17,308

Ingots account for 2918; pigs, 1125; bars, 9892; plates, 1453; cakes, 135; and rods and wire, 1785 tons.

With a record production of 27,000,000 lb. of copper in the Houghton district in July, and 28,000,000 lb. assured for August, if everything works out as planned, the output is breaking all records. The bulk of the copper produced is sold up to September, and in some cases to October.

LEAD

The difficulty in absorbing re-sale lots mentioned last week has been intensified. Demand has not improved in the past week; in fact, the reverse is true. The situation is dominated by re-sale lots which continue to make their appearance. Although consumers are continuing to use large quantities of this metal, they are evidently overstocked. In the past week the price of the leading interest has been reduced twice, thus proving that the belief of the producers that consumers would soon enter the market was wrong. On July 30, the price was reduced to 5.50c., New York, and on Monday, there was another decline of ¼c. In both cases, outsiders went still lower, going to 5c. on Tuesday. On Thursday holders offered the metal at 4.75c., but buyers were not attracted and the sales which took place later in the day were at 4.50c. Consumers are not in any hurry to cover future requirements, and it is understood that on contracts covering shipments over the remainder of the year the price of 4.75c. is being shaded. July exports were 2458 tons, and on August 4 a shipment of 20 tons was made to Batavia, Dutch East Indies, which is all that has been exported so far this month.

TIN

Although the tin consumption for the year is predicted to be larger than 1914, based upon July deliveries of 5300 tons, 4700 at the Atlantic seaboard and 600 on the Pacific coast, the market is quiet, and consumers are not in the market at present prices. On Wednesday the price was 35.50c., New York, and following the arrival the next day of 1505 tons, the price dropped to 34.75c. While consumers are well covered for several months to come, it is believed that should prices recede further they will enter the market. Future positions are not receiving much attention. There was some demand for futures a few days ago, but it is doubtful whether any business was placed or not. Speculation is entirely absent. The July deliveries of 5300 tons compare with 3900 tons for the corresponding month of 1914. For the three months ended July 31, 1915, the deliveries were 14,800 tons, against 11,350 tons for the same period last year. Stocks on hand August 1 were 991 tons, and the total afloat at the close of July was 12,070 tons, against 11,166 tons in June and 5519 tons on July 31, 1914. The total visible supply on that date was 16,084 tons. There was a sharp break in the London market on Thursday, Straits spot declining £2 10s. to £154 10s. against £160 10s. on July 29. The arrivals August 1 to 5, inclusive, were 1600 tons, and there were 6100 tons afloat on that day. About 200 tons of this is due to arrive within the next week.

New Machines and Devices

Information based on letters and catalogues from manufacturers.

Pipes at the Exposition

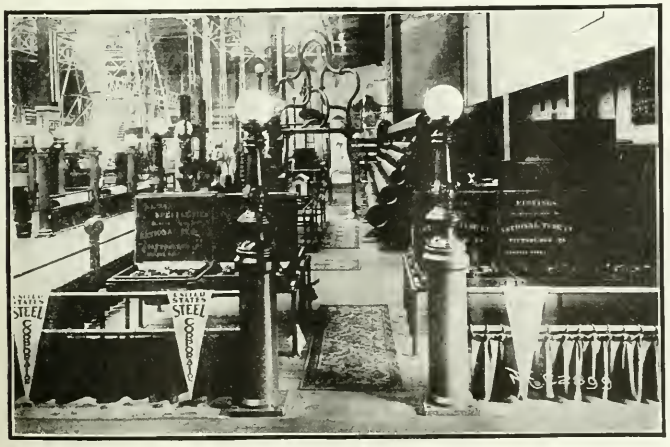
In the Palace of Mines and Metallurgy at the Exposition the U. S. Steel Corporation's exhibit covers a large area. Its subsidiary, the National Tube Co. of Pittsburg, has approximately 6000 sq. ft.

This company manufactures three closely related, and yet distinctly different, lines of products, and the exhibit naturally divides itself into the following sections, namely, (1) 'National' pipe and allied tubular products; (2) 'Kewanee' specialties, fittings, etc.; (3) 'Shelby' seamless tubing and cylinders. The display of National pipe and allied products is the largest of the three sections. This is as it should be, inasmuch as National Tube Co. has an annual capacity exceeding 1,250,000 tons of tubular products.

Entering the main section, the visitor walks through a large arch, 15 ft. high, made of miscellaneous bends of 4-in. National pipe. Immediately behind this is a massive rack, on which are displayed the various types of National pipe used in the oil-fields of the world. Capping this rack, is the largest and longest individual length of lap-welded wrought pipe ever made in America, consisting of one length of 20-in. O.D. National pipe, 39 ft. 6 in. long. This double length of pipe, was welded at the National works of the company at McKeesport, Pennsylvania.

The right-hand portion of the main booth is devoted to the display of Kewanee specialties, including the Kewanee union, 'NTC' re-grinding valve, brass fittings, cocks and valves, malleable and cast iron and wrought fittings. Probably the most commanding feature of this section is the colossal model, made to exact proportions, of a two-inch octagon Kewanee union. An eighth section has been cut from one side of the model in order to show in cross-section the Kewanee patented principle, which consists of (a) brass to iron thread connection, no corrosion, (b) brass to iron ball-joint seat, no gasket, (c) 125 lb. compressed air test under water, no defective fittings, and (d) solid, three-piece construction, no inserted parts. Nearby is a working model of a testing machine, designed and used to give each Kewanee union a 125-lb. compressed air test under water, thereby protecting the consumer against the possibility of receiving defective unions. A complete line of Kewanee specialties and fittings is neatly displayed on a multiplex, swinging-leaf, exhibit rack.

Across the aisle from the Kewanee section, in a separate booth, is the exhibit of Shelby seamless tubing and cylinders. Perhaps the most unique feature of this exhibit is a set of furniture, consisting of six chairs, one settle, and a table, made entirely of Shelby seamless tubing. The method of manufacturing seamless tubing from a square, flat plate, known as the 'cupping' process, is clearly explained in an exhibit which shows the various steps from flat to finished cylinders or tubes.



NATIONAL TUBE CO.'S EXHIBIT AT THE EXPOSITION.

Scientific Instruments at the Exposition

Among the many instructive booths in the Palace of Liberal Arts is that of the Bausch & Lomb Optical Co., Rochester, New York, and San Francisco. This firm supplied the Exposition with a large number of parabolic searchlight mirrors for night illumination. There are over 700 of them, and there are 48 searchlights 36-in. diameter. Samples of these are on view in the booth.

The engineering instruments shown comprise transits, levels, theodolites, tachymeters, and alidades. As might be expected from the advancement in all scientific apparatus, include novel features which appeal to engineers, surveyors, and architects. There is the inner focusing device in the telescope, by which the focus is adjusted without the lengthening or shortening of the tube, assuring practically permanent collimation adjustment, water and dust-proof conditions, and equilibrium of telescope. There is also the tubular compass-needle which is lighter and consequently of greater sensibility. The graduations are marked by great precision, and these instruments are claimed to have received a high reputation for accuracy, advanced design and durability.

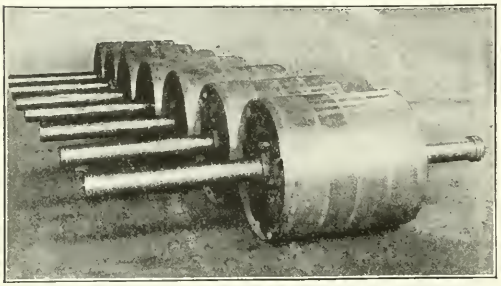
The 4½-in. tachymeter mountain and mining instruments are especially interesting. The water and dust-proof conditions, both as regards the telescope (due to the introduction of the interior-focusing system) and the mechanical construction of the plates, vernier-windows, compass-box, and vertical-circle guard, are considerations of the highest importance. The one piece U-shaped standard permits plunging the telescope at either end and assures the required stability and permanency so essential in a mining transit. A new manual of great value to the engineer will shortly come from the press, and will undoubtedly be highly appreciated by the users of engineering instruments, as the technical experts of this firm enjoy a high reputation among the profession. The firm has been awarded the Grand Prix at the Exposition.

Range-finders and periscopes naturally attract considerable notice at present. Bausch & Lomb make them up to 40-ft. long. Pamphlets distributed describe the range-finder, exophthalmometer, inter-

pupillary gauge, lens comparator, spectrum projector, keratometer, and the large Gullstrand phthalmoscope.

Magnetic-Separator Pulleys

The importance of removing 'tramp-iron' from material about to be delivered to crushers or pulverizers is recognized in modern plants. It is practically impossible to keep broken drills, coupling-pins, and other similar material out of ore and rock to be reduced. Those experienced in the operation of



MAGNETIC-SEPARATOR PULLEYS.

crushing plants know what costly and vexatious delays are caused by the presence of tramp material. Magnets have been sucessfully used. The magnetic-separator pulleys shown in the photograph were recently sent to the Washoe reduction works of the Anaconda company from the Cutler-Hammer Clutch Co., Milwaukee.

Wood Pipes and Tanks at the Exposition

From the Redwood Manufacturers Co.'s plant at Pittsburg, Contra Costa county, California, have been displayed in the Machinery, Mines, California, and other buildings at the Exposition a lot of interesting products. In the first named is a 17,000-gal. capacity Remco tank connected with 12-in. machine-banded Remco pipe and a 80-hp. Bessemer engine and 12-in. Advance pump, 5000 gal. of water per minute being pumped through the 12-in. redwood stave-pipe at a velocity of 11 ft. per second; samples of Remco machine-banded pipe of standard make in various diameters from 2 to 24 in.; samples of Remco continuous-stave redwood pipe as erected in the field; samples of Remco machine-banded pipe wound with copper wire, furnished where acid or strong alkaline solutions are used; a section of 18-in. Remco continuous-stave pipe taken from the main flow-line of the city of Logan, Utah, in June 1914. This pipe-line, from which this piece was cut, was installed by the firm in 1892, and has been in continuous service for 23 years.

Outside of the Machinery building is the 50-ft. Remco tower, surmounted by 30,000-gal. capacity Remco redwood tank, and supplied by 1500 ft. of 6-in. Remco machine-banded redwood stave-pipe. The pipe runs underground from San Francisco bay, and salt water is pumped through it and into the tank, against a 75-ft. head. This exhibit supplies the water for the cooling system in the building.

In the Mines building are three Remco redwood tanks and two towers exhibited by the firm in connection with the L. C. Trent Engineering Co. These tanks are in actual service, containing machinery and holding cyanide solutions.

Much of the sewer and drainage-pipe in the Exposition grounds are of the Remco brand. This is made either as continuous-stave or machine-banded. The former is made of redwood staves averaging 14 ft. long; the latter in sections 8 to 20 ft. long, and shipped ready to be laid.

Commercial Paragraphs

The JANTZ & LEIST ELECTRIC CO., of Cincinnati, Ohio, sends us photographs of its generators for all purposes.

A directory (133 pages) of piston-ring sizes has been published by the BURD HIGH COMPRESSION RING CO., of Rockford, Illinois.

A large proportion of break-downs in electric plants are due to improper operation of commutators and brushes. Graphite brushes are designed to reduce these troubles, according to the JOSEPH DIXON CRUCIBLE CO., New Jersey.

A new pipe and nut wrench is being manufactured by the HAYWARD WRENCH CO., 700 Cass avenue, St. Louis, Missouri. The tool is said to be the only automatic-combination, self-adjusting pipe, nut, and ratchet wrench on the market.

The WOOD DRILL WORKS, of Paterson, New Jersey, manufacturer of rock-drills, mining, tunneling, and quarrying machinery, has issued a useful catalogue on its drills. Details are given on every part of the machine, hose, and prices.

A new method of recording the cost of various operating conveyor-belts has been worked out by the B. F. GOODRICH CO., of Akron, Ohio, in the interest of all belt users. A record-card of explanation will be mailed by the firm on request.

On July 16, the U. S. Bureau of Mines approved for safety, practicability and efficiency in general service the miners' portable electric cap-lamp known as the 'Manlite No. 8,' manufactured by the MANNESMANN LIGHT COMPANY OF AMERICA, 331 Fourth avenue, New York.

The MORSE BROS. MACHINERY & SUPPLY CO., of Denver has recently installed a complete flotation testing-plant in its Denver store-room. The use of the plant is offered free to those wishing to make their own tests and experiments along this line. Competent assistance is also given to those desiring it, and free preliminary tests will be made on any ores or tailing sent in. A number of the recent flotation installations in Colorado have had their inception at this complete plant. The firm recently shipped seven carloads of machine-tools to various manufacturers in the East engaged in war-contracts. Most of the equipment was turret and engine-lathes.

Catalogue F of the DE LAVAL STEAM TURBINE CO., Trenton, New Jersey, in 64 pages describes and illustrates its centrifugal blowers and compressors. Many advantages are claimed for these types of machines which are used for the economical handling of air at all pressures from 5-in. water-column to 125 lb. per sq. in., single-stage and multi-stage compressors arranged for steam-turbine, motor, and belt-drive. Laws of compression, design, construction, tests, influence of blade shape, power-limiting characteristic, head-delivery characteristic, uses of the single and multi-stage blowers, and other products of the firm are discussed in an interesting manner. At the Swedish pavilion at the Exposition at San Francisco, De Laval turbines are shown as used for various plants.

The HUMPHREY internal combustion pump as installed at Chingford, London, England, with a daily capacity of 180,000,000 gal., and that in Egypt with a capacity of 792,000,000 gal., was discussed in the PRESS of June 28, 1913, and July 18, 1914. A 66-in. pump is to be installed on the Bedell-Moore estate, near Del Rio, Texas, where it will be used for irrigation purposes, and was manufactured by the HUMPHREY GAS PUMP CO., of Syracuse, New York. The pump, with the 'play-pipe,' takes the form of a short-legged V, the apex of the V, or base of the pump, being firmly bedded in the concrete base of the pump well, while the upper end of the play-pipe comes through the bottom of a concrete surge tank, from which the water is delivered to the main outlet channel. Gas will be supplied by a 300-hp. Akerlund down-draft producer, using either soft coal or mesquite wood, the latter being found on the land. The operating floor of the plant is just about low water-level of the Rio Grande river.

EDITORIAL

T. A. RICKARD - Editor

GOLD is coming to San Francisco from Australia and shipments of South African gold are on their way to New York.

WITH the pound sterling at $4.64 and the French franc at 17c., the eagle on the dollar may be forgiven if he screams even without being pinched.

PUNNING phrases are becoming common in serious discussions. "Has regulation regulated?" says one. "Is the efficiency engineer efficient?" asks another. Such begging of the question under guise of cheap wit detracts from the seriousness of the subject and can do no good. It repels the reader.

BUTTE & SUPERIOR, the first American mine to figure in flotation litigation, made an operating profit of $2,107,153 in the quarter ending on June 30 last. This is equal to $7.74 per share on the 272,018 shares issued. The company is producing zinc at the rate of 127,000,000 lb. per annum.

GROWTH of optimism is manifest all over the country. Crops, general trade conditions, and the relations of the Government with the belligerents in Europe all contribute to a cheerful tone. The steel industry is expanding splendidly, in response to foreign buying, war orders, and domestic consumption. Foreign exchange is abnormally low.

ON December 16 the Mining and Metallurgical Society will hold a special meeting at Washington for the particular purpose of calling the attention of Congress and the administration to the need for a revision of the mining law. It is important that an influential attendance should be secured and that the Pacific Coast mineral region should be well represented.

PATENTS are given two pages in this issue. We aim to record the most interesting of the metallurgical patents granted in the United States. Previous excerpts appeared on July 17. On this occasion, it will be noted that Salt Lake City is prominent as the address of several patentees. We are not surprised, for in the city by the saline strand are many energetic and resourceful engineers.

SOMEBODY at Cobalt has sent us a local paper in which a glossary of mining terms is given. The conspirator has marked the definition of 'ore:' this reads "Compound of metals with oxygen, sulphur or arsenic, etc." He expects a rise—not a 'raise.' We refuse to add to the belligerency of the times, for we want peace, with honor. Therefore we rest content with expressing a high appreciation of the "etc," *that* gives an artistic touch to the definition, for it includes things in the air, on the earth, in the waters under the earth; indeed it renders all other definitions supererogatory.

FLOTATION by froth is being used in the mills of the south-east Missouri lead region, which includes the St. Joe, Doe Run, and Bonne Terre districts. The process is applied to the slime, or classifier-overflow. No question of royalty has arisen as yet. Seven mills crushing from 2000 to 4500 tons per day are involved, the modification of practice having been outlined for the local mill-men by Mr. H. A. Guess from his work in the Federal mill.

WE are in receipt of the first issue of *Teniente Topics*, a magazine published by the staff of the Braden Copper Company, in Chile. The name is derived from the fact that the lode was discovered by a fugitive lieutenant or *teniente*. We note also that the smelter settlement formerly called Molino has been re-named Sewell, in memory of the late Barton Sewell, the former president of the company. This first issue is excellent. It contains a historical account of the enterprise by its founder, Mr. William Braden, and an introductory article by Mr. S. S. Sorensen, the present general manager for the company, who was formerly with the Nevada Consolidated Copper Company. Descriptions of the races, of tennis matches, of a hunting trip, and a Spanish supplement serve to give variety to the magazine. We congratulate the business manager of the publication, Mr. J. F. Pearce, superintendent of supplies, and the editors, Messrs. L. E. Grant and A. T. Wood.

SPELTER has dropped from 26 cents per pound on June 14 to 12¼c. on August 14, while copper has decreased in price during the two months from 20¼ to 17c. These declines are not surprising, having regard to the rapidity with which quotations were hoisted as soon as it was realized that much copper and zinc would be required for manufacturing munitions of war. A flood of buying orders followed. Since then purchases have been postponed in the expectation of cheaper metal, but a resumption of buying is supposed to be imminent. For the good of the mining industry we would like to see zinc firmly stationed at, say, 10 cents; for that price, if assured, would mean handsome profits to the producer without crippling allied industries, such as that of galvanizing. As for copper, the resumption of production at full scale by the chief producers in this country, together with the beginning of a magnificent

output at Chuquicamata by the Chile Copper Company, plus the rush of metal from Alaska, has caused production to exceed consumption. Copper at over 20 cents is unhealthy, for, apart from the uncertainty of the market position, it stimulates the exploitation of a lot of mines that on average prices cannot expect to be operated profitably. Most of us would be content to see copper firmly placed at 17 cents, rather than making violent fluctuations of 5 cents, up or down. In short, steady prices and a normal market are best in the long run.

MEXICAN affairs have not yet come to the point of decision. The Pan-American appeal to the factional leaders and to the people of Mexico was made public on August 14; if the "reasonable time" suggested as sufficient to enable those interested to arrange a conference be assumed to mean 10 days, we must wait until next week to know whether President Wilson's latest move is to prove successful. Although Carranza has exhibited no conciliatory spirit so far, it is hoped that he will defer to the sentiment of the country, which is supposed to be weary of the endless strife and brigandage. Villa, Zapata, and others appear willing to stop fighting. Meanwhile our local press has published a large number of scare dispatches of a most foolish sort, including talk of a threatened invasion of Texas by Mexican revolutionists, as if the whole history of the Rio Grande border did not ridicule such a suggestion. So far nothing serious has happened on the frontier except the irresponsible incursions of stray outlaws; these incidents have no political significance and the exaggeration of them is grossly misleading. The real test is yet to come. If the joint message of the United States and the South American republics is disregarded, then our Government will have to act, or be stultified. The South American governments will do nothing but give their approval to the further steps necessary; they will not participate in any naval or military measures. We hope that further action may not have to be of a military character, but if Carranza proves recalcitrant while the others are willing to compose their differences, then coercion may be necessary, in the form of another military occupation of Vera Cruz and the stationing of a garrison in Mexico City until such time as a stable government can be restored—as was done in Cuba. By this time the people of Mexico, and Pan-America, must realize that the United States has no sinister design on Mexico, for President Wilson has been forbearing almost to a fault and has shown repeatedly his earnest hope that intervention might be obviated.

Wanted: Criticism

In a recent bulletin of the Canadian Mining Institute there appears a vigorous letter from Mr. G. R. Mickle on the subject of 'Voluminous Pseudo-Scientific Rubbish.' The mere title is a call to arms; we like people who throw away their scabbards and hurl themselves into the fray with real joyousness. Of the making of books there is no end and much piffle is a weariness of the flesh. Mr. Mickle even attacks the U. S. Geological Survey and instances a particular report on 'Natural Gas in 1913,' which gives a large number of analyses, some trustworthy and others untrustworthy, so jumbled as to render the data as a whole worthless to a serious enquirer. Moreover, the compiler of this misleading information appears to have ignored a previous and valuable volume on this very subject published by the U. S. Bureau of Mines. In the first place, whether the matter criticized be pseudo-scientific or not, we may point to the waste of public money in publishing information on the same subject in two reports from two separate Government bureaus. Of course, this is due to the effort of each organization to prove its efficiency, in order that it may receive large appropriations from Congress. Efficiency ought to include co-ordination of effort. However, that is another subject; let us return to the idea of "voluminous pseudo-scientific rubbish." Undoubtedly the general use of the typewriter, the cheapness of paper and printing, the spread of education, and the love of publicity have joined in causing a deluge of inane verbosity. The amount of matter now published on technical subjects is so vast that no editor can even skim it; no professional man can begin to read even the part relating to his own specialty; no index has yet been devised that will enable him to lay hands on what he most requires, because no index is discriminating. Technical papers grow in size and number, without corresponding improvement in quality, because the facility for writing is far ahead of the faculty of criticism. Technical societies issue fat bulletins, diffuse and unedited. Government bureaus base their appeals for financial support largely on the bulkiness of their publications. As for the Geological Survey, which has done, and is doing, work recognized to be so good that no praise from us is necessary, it also is the victim of the voluminous; for every State and every mining centre demands one or more volumes, so portly and so elaborate that by the time they have emerged from the printer they may be out of date. Multiplicity, bigness, and pretentiousness mark the prevailing style in volumes, reports, bulletins, and papers. What is needed is criticism, such criticism as will illuminate the essential and drive the unessential into the outer darkness of extinction. Most of us had become impatient with the critics, sneering at them as the incapables that had learned to destroy because they had failed to create, we preferred the constructive to the destructive, we looked upon the 'knocker' as a nuisance. Thus we have done our best to expel the real enemy of verbose writing, the natural check on the multiplication of verbiage. Indeed we have become so good-natured and so undiscriminating that the critic feels his function, if not gone, to be so little used as to be best allowed to pass into atrophy or become ankylosed. The cure is to be more critical ourselves, refusing to be impressed with mere bulkiness or to become mentally dyspeptic on a diet of half-baked technology. One or two independent editors, a few courageous secretaries, and some discrimi-

nating committees on publication, backed by readers of technical periodicals and members of professional societies earnestly desirous of less quantity and more quality of literary output would achieve the purpose for which Mr. Mickle lowered his lance.

Should Directors Speculate?

In continuation of our comment last week, we suggest that the answer to this query hinges on the further question whether a director goes on the board, for example, of a mining company (1) to safeguard his own interest in the property, (2) to protect a small group, by whom he has been nominated to the office, or (3) to act as a trustee for all the shareholders. If he is on the board merely as a privileged speculator, then he may reply, as one director did, that "self-preservation is the first law of society." But it is a poor proverb that won't work both ways. The first law of society is to protect itself against larceny. In all business combinations the idea of loyal co-operation is implicit; this involves the subordination of self-interest to the general good of the enterprise. Even bandits recognize that they must hang together or else run the risk of hanging separately. Joking apart, loyalty is the first mark of a good businessman. Without it, no continuity of joint action is practicable. Does the feeling of loyalty on the part of a director extend from himself to the general body of shareholders? Obviously not in the case just quoted. That director is on the board to get an advantage, to which he, quite frankly, considers himself entitled. It is not worth while to discuss the question with him, but a wise shareholder will neither support him for re-election nor hold stock in any company in which he, the self-preserver, has a controlling voice. Next we come to the nominee who is on the board to protect, not the company as a whole, but the interest of a particular group. He has advanced from the egoistic point of view to the broader position of helping his friends. This seems a nicer sort of business, but in effect it is even more dangerous, for a man's sense of loyalty to his friends will allow him to do for them what he would not do for himself, and a group will employ tactics that any individual in the group might spurn. Morality is diminished by addition, paradoxical as it may seem. The public has often suffered severely from the manipulation incidental to group tactics in company affairs. But it cannot be helped, you say. In large affairs the capital is subscribed by groups, each of which expects representation on the directorate. Yes, but there are groups and groups. Some of them realize their obligations to minority shareholders. They are worthy of support and they are safe leaders to follow.

Finally, we come to the director that has the sense of trusteeship to all the shareholders. He is uncommon. If he is to become less rare, he must be cordially supported. By him, and through the confidence he engenders, it will be possible to get the public to contribute to corporate finance in mining enterprise. Even promoters and financiers are beginning to observe a higher code of conduct. We know a particularly clever and successful man of this type who makes it a rule not to deal—buy and sell at short intervals—in the shares of those companies for which he is a director, confining his in-and-out transactions to enterprises in which he holds no fiduciary position. If he wants to carry out a share-deal, he resigns from the directorate, so as to have his hands free. If directors could be inoculated with that idea, the atmosphere of mining would become less malarial.

Another director replied that he had "a perfect right to sell—provided he stopped selling when he had disposed of his stock. To sell short is to hurt the company. A director who took advantage of inside information to sell shares in his company that he does not own ought to go to jail for it." The less said about jail the better. The self-preserving directors would consider it bad form to use such language. But is it more heinous to sell shares you do not own than to buy shares for which you cannot pay—is a 'bull' or a 'bear' the more gentlemanly beast? The argument that it is more wicked to sell than to buy is untenable. If you grant the right to gamble in the shares of a concern in which a man is a trustee, you yield the whole position. Whether his operations are moderate or immoderate, becomes no longer your business, but his. The idea that a 'bull' helps his fellow-shareholders, by improving their market, and that a 'bear' spoils the property he owns in common with other shareholders, is to play fast and loose not only with morality but with logic. In either event the stock becomes valued at a fictitious price and innocent people are deceived. We have an inveterate idea that money should be made in mining by producing metals profitably and not by gambling with loaded dice.

Another director, the chairman of a large State institution, testifies that "a director is chosen primarily because of his standing in the community, his experience and judgment being expected to be of value to the corporation. He is not put upon the board because he has a large amount of stock and so should be given access to more information than he would have otherwise. In other words, he is chosen for the company's good, and not his own." Here we begin to see the dawn of a better day. Compared to the talk of some of his colleagues, this gentleman's opinions sound like the ideals of an Ultima Thule. Nor is he a lone voice in the wilderness, for Sir Thomas Shaughnessy, the president of the Canadian Pacific Railway, says: "It has been an understood thing from the beginning that no director should either speculate in stock or should take advantage of any information secured in consequence of his membership on the board. In all my experience there has never been an occasion to find fault with any member of the board for speculating in stock or for utilizing to his own advantage inside information that he possessed, and I have never found it necessary to ask any officer of the company to tender his resignation because he was engaged in affairs that were not consistent with his duties to the company." That is a notable utterance and fittingly brings the discussion to an end. The graphic curve of business ethics has taken a decided turn upward in railroad and other

industrial affairs. We do not doubt the existence of a similar tendency in mining. Our own retrospect of 30 years in the business of mining, as engineer and journalist, gives us strong hope of continued improvement in financial conduct. Further betterment lies in the crystallization of public opinion as regards the trusteeship of directors.

The New Metallurgy

In this issue we publish an interview with Mr. Charles Butters. We feel sure that it will interest our readers, particularly the many friends of Mr. Butters in various parts of the world. To the younger men it should be a delight to read how one of their recognized leaders utilized the experience of life to such manifest advantage. On its human side the story proves that the mistakes of a sagacious man are merely stepping-stones to success. It also affords a striking example of that intensely American characteristic: the willingness to scrap anything that is useless in order to make way for something that is useful. The enterprise and initiative of our metallurgical hero furnish a splendid example to youth; to older men his quick decisions seem like playing with fate. It is not too much to say that in his eagerness to learn and his daring to put thought into action, Mr. Butters is a fit exponent of the modern idea at its best. Leaving the human side of the story, we turn to the technical. From amalgamation to chlorination, from chlorination to cyanidation this eager seeker of applied knowledge has progressed. Now no longer young, he finds himself facing a new departure; a new process that promises to revolutionize the concentration of ores on a world-wide scale. Does he feel annoyed to have his personal experience with other processes seemingly set to one side? No, with all the joyousness of a keen student he enlarges his home-laboratory and organizes a staff for earnest research. Testing the slime and other mill-products from the mines in which he is financially interested, he ascertains the applicability of the flotation process. Meanwhile samples of ore are sent to him from widely separated localities and upon them also he tries the effects of flotation. A metallurgical vedette, he is determined to keep in the van of progress. To us, and to our readers, we feel assured, this episode is both interesting and significant.

The information given by him concerning flotation is timely. It will be noted that the experiments made at Berkeley are all done with alkaline solutions. This in itself is noteworthy, for the use of acid has been a prominent feature of earlier flotation processes, because the acid accentuated the selective adhesiveness of oil for metallic particles as compared with the earthy gangue-minerals. But the most interesting information given in the interview is that dealing with the flotation concentrate. So far, at the lead-zinc mines of Broken Hill and at the big American copper mines using the process, the question of treating the concentrate itself has been shelved, for a ready market was furnished by the smelters. In many isolated localities, in Mexico or the West, the reduction of the concentrate on the spot is advisable, if not imperative. As to this, Mr. Butters makes some suggestions.

Moreover, his frank acknowledgment of lack of knowledge concerning certain phases of the process is instructive. As a matter of fact, the technology of flotation thus far has been mainly developed in the wake of a peculiarly vindictive litigation. The Law is not a good teacher of science. Indeed, of the literature of the subject to date it can be said that nine-tenths of it is hopelessly vitiated by the prejudices of patentees, process-mongers, and litigants. Most of the men experienced in the flotation process are either tied to the company claiming a monopoly in the use of it, or they are in the employ of the companies that are contesting that monopoly. In consequence, the amount of reliable information available is small. The metallurgists who have been largely instrumental in developing the agitation-froth process are under orders not to write or talk, for fear that they may hurt the cause of their employers in law-suits now pending, and that have always been pending since flotation—whether by oil, gas, or froth—first became of any consequence. On the other hand the metallurgists and mill-men associated with those who are confessedly infringing the disputed patents are in no position to give the profession the benefit of their experience with such frankness as they—and we—would desire. Meanwhile, if the mining industry is not to suffer, we must all try to break this embargo on knowledge. The Mining and Scientific Press has done so lately—not without success. And without injury to anyone. Our aim is to be helpful to many and injurious to none. Our sympathy goes to the clever men, especially those connected with the Minerals Separation Company, that are unable to expound the technology of the process or win the distinction that comes to specialists in a branch of the art growing rapidly in importance. We sympathize likewise with those who are making preliminary tests with flotation on their own ore and find it difficult to get proper guidance. With the assistance of a few independent investigators, we shall hope to remedy that deficiency. It is the province of technical journalism to gather information where it can, for the general good, and serve as a clearing-house of ideas to the professional men scattered among these widely-separated localities where the metals are won from Nature. The least that we can do is the best that we can do. The need for information is urgent. At a time when the base metals are intensively demanded for warfare, and in preparation for a time when they will be in still greater demand for peaceful purposes, it is peculiarly unfortunate that a process of apparently such wide usefulness should be stifled in the ill-ventilated atmosphere of the law-courts. In our next issue we shall publish an article on flotation at Anaconda by Mr. E. P. Mathewson and in subsequent issues we shall make further efforts to give our readers the latest information on a process, that, as Mr. Butters says, "has started a new era in the concentration of ores."

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment

Preferential Flotation

The Editor:

Sir—Your issue of June 26 contains a paper by O. C. Ralston on 'Preferential Flotation.' Owing to the author having confined himself to a study of American patents, incorrect presentations of chronology have arisen. In particular, Mr. E. J. Horwood of the Broken Hill Proprietary suffers, for his invention of the fractional-roasting method is made to date three years later than that of Mr. H. A. Wentworth. It is due to Mr. Horwood to say that he had carried the process into practice some years before 1912. In fact he had published, in the early part of 1910, details of results obtained on a practical scale, articles appearing in both the *Engineering and Mining Journal* and *The Mining Magazine*. Moreover, he described the modification introduced for the purpose of obtaining an increased proportion of the silver in the lead concentrate in a paper read before the Australasian Institute of Mining Engineers in 1913.

EDWARD WALKER.

London, July 24.

[Wentworth obtained his United States patent on January 2, 1909, while Horwood's first patent in Australia is dated January 13, 1909. Mr. Walker's exception is well taken.—EDITOR.]

A Hypothetical Case

The Editor:

Sir—In view of the controversy in the PRESS and other technical papers regarding the scarcity of mines, etc., it would seem justifiable to discuss one phase of the cause bringing about the present effect, that has not yet appeared in print.

As the owner of a shipping property I was reviewing in my mind one evening, while indulging in a fragrant havana, the future developments contemplated, based on present knowledge and future possibilities. During this day-dream, visitors, who introduced themselves as experts, interrupted me with a desire to know at what value I held the mine? On the impulse of the moment I replied "One million." They then requested that they be allowed to examine and sample the property.

Mr. Smith was spokesman for the party and his sublime seriousness impressed me. Regaining my senses, I asked him why he wanted to buy the mine? He answered "For investment." "Well," I said, "I also am an expert looking for investment and if the mine is worth a million to you, it certainly is worth that much to me, so why should I sell it?" "In fact," I added, "I could only have two objects in view: One being to take advantage of you because you over-estimate the value, by assuming that you can see unreasonable further possibilities, or, because I have no faith in my system of valuation. Being honest and reliable I have placed the true valuation according to the highest engineering standard, then how can you expect to realize on this investment?" Possibly some of the experts can answer.

MINE-OWNER.

Goldfield, August 10.

[Persons—particularly engineers—who buy mines "for investment" are deservedly regarded with suspicion. A mine is a speculation—a good or a bad one, according to luck and skill, particularly luck. Probably Mr. Mine-Owner would have been ahead of the game if the 'expert' had advised the purchase of the claim for that iridescent million.—EDITOR.]

Platinum Assaying at the Boss Mine

The Editor:

Sir—The article by F. A. Crampton on this subject is timely and it is to be hoped that it will be productive of profitable discussion. To that end I wish to make some remarks, based on memory, since my experience in platinum assaying dates back ten years and the notes I made during that period are not available at the time of writing.

Mr. Crampton draws attention to the discrepant results obtained by different assayers. I quite agree with all he says as to the difficulties of the analysis and the unfamiliarity of the average assayer with the necessary manipulations. But it must also be remembered that the platinum is presumably present in this ore in metallic form (as indicated, though not definitely stated, by Adolph Knopf in Bulletin 620-A of the United States Geological Survey) and all assays of material containing metallics are characterized by annoying discrepancies. This factor will persist in spite of improved technique on the part of the assayer. It is worth noting that in this ore, as in that of the Rambler mine, Wyoming, the amount of palladium present exceeds the platinum. No one knows in what form the palladium exists. Some ten years ago I expended much labor in an effort to separate and identify the palladium mineral in the Rambler ore, but without success, as I was unable to find any solvent that would attack the other constituents without dissolving the palladium mineral.

An important factor in the analysis of the Boss ore is that, aside from a little iridium, it seems to contain no other metal of this group. It is this that makes the simplification of procedure suggested by Mr. Crampton a possibility. The two methods given by Ricketts and Miller are not 'standard' ones; they are the methods devised by the late Dr. Miller to treat the materials he was called upon to analyze. When I was assayer for the Orford Copper Co., and had to make regular analyses on the precious metal residues from the Sudbury anode slimes, containing almost every metal of the platinum group, I used a method that was a legacy from my predecessor. It was even more complicated than the method described by Mylius and Mazzuchelli* and took about ten days' time to complete. I would have been glad to employ a simpler method, but it is a chemical impossibility to separate all these elements without going through a tedious process. The worst difficulty is referred to by Mr. Crampton, namely that the precipitations are apt to be incomplete, thus in attempting to precipitate silver from a platinum-bearing solution, you obtain a silver chloride precipitate containing some of the platinum, and a platinum-bearing filtrate containing some silver. The relative proportions of the metals present also affect the analysis. This is the peril which besets any short-cut method; it may work perfectly on an ore of the character for which it was devised, but on a different ore it may give erroneous results. It seems likely that assayers will have to continue to do what Mr. Crampton, and nearly every other worker in the analysis of platinum-bearing materials, has done; namely, devise for himself a scheme of analysis that most nearly meets his needs.

THOMAS T. READ.

San Francisco, August 16.

The Search for Platinum

The Editor:

Sir—From your recent editorial on this subject it is clear that this metal will be sought with growing zeal during the next few years. The price, which has risen so remarkably since 1890, will be increased still more by the export-tax of 30% to be imposed by Russia in July. (The possibility of this tax you foresaw, stating that it would be borne entirely by the foreign consumer.) During the next decade Russia will levy from every available source of revenue. That may result in a much heavier burden upon the consumers of platinum. Platinum being one of the necessary metals and its utility depending largely on its unique properties, it may be possible to go a long way in taxing the traffic all it will bear. In fact, during recent years consumption has become continually greater in the face of a soaring price. In addition to the above considerations it will be remembered that Russia produces 95% of the world's supply. North America being the greatest consumer, it is interesting to speculate regarding the existence of important deposits on this continent, and with that end in view to consider the nature of the deposits of platinum already known in various parts of the world.

Platinum occurs in various igneous rocks and ores as a primary constituent, in veins and contact deposits, and in placers and beach sands. Other occurrences are known, but they are likely to remain of scientific interest only. Some cited by F. W. Clarke[1] are: in certain Pennsylvanian shales; in ironstone, ferruginous claystone, and decomposed gneiss from Australia; in the ash of some Australian coals; in limonite nodules from Mexico; and as sperrylite in pegmatite at Copper Mountain, British Columbia.

Russia's production is wholly from placers. This is true for the rest of the world also, except for that recovered from nickel ores at Sudbury, the trifling amounts obtained in refining gold and copper in the United States, the future output from the Boss mine, in Nevada. It is natural, therefore, to consider placers as the most promising field of search for platinum. In some gold placers this metal is present in sufficient quantity to form an important by-product, but the total yield from this source in North America is negligible in comparison with the consumption. And while the future will surely see greater attention given to the recovery of the platinum metals from gold placers, as well as to the saving of the finer particles now recognized as an unavoidable loss where only riffles are used, it is safe to assume that this total cannot be materially increased in comparison with other sources of supply. However, the Russian platinum is found in placers that, for the most part, carry little or no gold. Referring to the deposits of the Nishni Tagilsk district, neither Beck nor Stelzner-Bergeat mention in their treatises on ore deposits the presence of gold, though the first author gives an analysis of crude platinum which shows 0.04% gold. Hence it seems possible that similar platinum placers may exist on this continent, and that they have been neglected on account of their lack of gold.

Lode-gold occurs in association with granite and its metamorphic derivatives, whereas the mother-rocks of platinum are of the basic magnesian kind. The gold-seeker may therefore find no gold to attract his attention when he comes across a rich deposit of platinum in placer form. Sometimes, however, gold does accompany the platinum, as in several of the Ural placers and in the important ones of Colombia, where it exceeds the platinum. There is the same association in the placers on the Tulameen river, in British Columbia, which has yielded the two metals in the proportion of one of platinum to three of gold. The latter locality has not proved important, but it is, I believe, the only example on this continent of the conditions to be borne in mind by the prospector seeking platinum. He must confine his search to districts where the proper physical conditions for the formation of placers exist, or have existed in the past, and, judging from all known cases, to districts where there are bodies of olivine rock (peridotite and some

*MINING AND SCIENTIFIC PRESS, March 27, 1915, p. 481.

[1]'Data of Geochemistry,' by F. W. Clarke, U. S. Geol. Surv., *Bull.*, 491, pp. 670-2.

serpentines) or pyroxenite. In the Nishni Tagilsk district the various platinum-bearing streams head in an area of olivine rock (approximately 120 square miles in extent) surrounded by a rim of pyroxenite. Both these rocks contain the metal, but chiefly the former. The placers produced during the erosion of this limited mass of olivine rock have yielded approximately 3½ million ounces and are still being worked; but all attempts to extract the metal directly from the rock itself have been unsuccessful. The land surface here has been exposed to the atmosphere since the close of the Paleozoic epoch at least, and the richness of the placers may be due to the tremendous amount of rock disintegrated in that time.

The following remark by Stelzner referring to these placers is of significance to the prospector. "The precious metal (platinum), according to R. Spring, came originally from the olivine rock, and it is never accompanied by quartz or gold in its placers lying in, or adjacent to, the area of olivine rock." Grains of chromite and magnetite, and to a less extent spinel, are its usual associates. The grains of platinum are commonly coated with a film of iron oxide, probably due to the oxidation of iron, which is apparently always a constituent of native platinum. Finally it may be noted that the olivine rock, usually more or less altered to serpentine, weathers readily. It may, therefore, be only sparingly represented in the gravel of streams cutting its mass, while other rocks, more resistant but perhaps not so important in quantity, form the bulk of the gravel.

The discovery of the high content of platinum in the ore of the Boss mine[2] and the noteworthy fact that it remained for 30 years undetected directs attention to the occurrence of platinum in lodes. Previous to this discovery platinum had been known since 1909 in the same county of Nevada in association with copper and nickel in the ores of the Copperhill district south of Bunkerville. It may be expected that further deposits of this nature will be discovered in this part of the West. Here it may well be noted that whereas assayers sometimes, if not usually, overlook appreciable quantities of the platinum metals in spite of their easy detection on the cupel, they very often find them when searching where they do not exist. I recollect several instances, of which the following is the most instructive. In the autumn of 1911 a widely-known metallurgist announced the presence of platinum in profitable quantity in certain basic dikes near an important town in British Columbia. Later his discovery of a new metal of the platinum group ('canadium') from the same source was reported, and descriptions (?) of it appeared in scientific journals the world over. There was much excitement locally and claims were staked for miles along the dikes. The Minister of Mines in his report for that year said that a large plant to treat these ores was being erected. Yet, when numerous samples were taken from the various dikes alleged to contain platinum in profitable amount, and sent to the three foremost authorities for careful testing, the result in each case was that no trace of platinum was found. The analysts were A. R. Ledoux & Co., F. P. Dewey, chief assayer of the U. S. Mint, and Johnson, Matthey & Co., London. Nevertheless various other assayers continued to have better luck than these, and the excitement was slow to subside. Indeed, even yet some intelligent people in that locality cling to the belief that the platinum is really there, explaining earnestly that the authorities mentioned failed to find it from not using the proper method of analysis! The moral is that the best services should be sought in the detection of small quantities of this valuable metal and that reports of other than reputable experts should be entirely disregarded, alike whether negative or confirmative.

Besides those mentioned there are other occurrences of platinum. While none has yet proved of important commercial value, some give promise of providing a profitable source. Those known are enumerated below.

(1) A gold-platinum contact deposit near the village of Sipongi, Sumatra[3]. An intrusion of granodiorite has metamorphosed a limestone bed of the Paleozoic schists of the district. The lime-silica rock thus produced was found to be composed as follows: 85 to 88% wollastonite, with some disseminated bornite, 12 to 14% garnet (grossularite), and 5% bornite with a crust of chalcocite. In small amounts there were also magnetite, pyrite, braunite, rhodonite, and calcite, with drusy crystals of pyroxene and calcite. A sample of decomposed wollastonite contained 0.15 oz. platinum per ton, 0.1 oz. gold, and 0.05 oz. silver, while samples rich in copper gave only a trace of platinum, 0.35 to 55.2 oz. gold, and 0.35 to 13.44 oz. silver. A short distance from the outcrop, a concentrate obtained from the river sand exhibited small particles of light-colored gold and grains of light-colored platinum 0.1 to 0.3 in. diameter.

(2) A gold-palladium contact deposit near Candoga, Minas Geraes, Brazil[4]. The country-rock, itabirite, is a crumbly sediment of Paleozoic or earlier age and consists chiefly of quartz and specular hematite, the latter usually predominating. Intercalated are thick lenses of lime-silica rock called jacutinga, the result of the action of an intrusion of granite upon the original calcareous strata. The jacutinga consists of the following minerals in proportions that vary greatly: diopside, actinolite, chondrodite, calcite, dolomite, magnetite, and ilmenite, together with grains of gold and bright copper-red jagged plates of palladium-gold. Some native platinum is also seen.

(3) A platiniferous quartzite from New Zealand[1] has been described.

(4) As long ago as 1849 platinum was detected in chalcocite in a gangue of dolomite, quartz, and barite at Chapeau mountains in the French Alps.

[2]'Platinum in Southern Nevada,' by Adolph Knopf, MINING AND SCIENTIFIC PRESS, June 5, 1915, pp. 876-9.

[4]'Uber das Vorkommen von Palladium und Platin in Brasilien,' by E. Hussak, *Sitz.-Ber.* Kais. Akad. d. Wiss., CXIII, Abt. 1, 1904. Summarized in 'Lehre von den Erzlagerstätten,' by R. Beck (3rd. Ed., 1909), Vol. I, p. 166.

(5) Traces of platinum were discovered by R. W. Brock in sulphide-bearing quartz at the Mother Lode claim, Yale district, British Columbia.

(6) In northern Finland pyritic gold-quartz veins have long been known.[5] Besides 0.05 to 0.1 oz. gold and 0.05 to 0.07 oz. silver per ton there is 0.01 to 0.05 oz. platinum. The vein filling is usually more or less brecciated, and seldom banded. It is composed chiefly of quartz and siderite, with some calcite and dolomite; and a little magnesite, hematite, magnetite, pyrite, arsenopyrite, and chalcopyrite.

(7) The following remarkable deposit is described at Katanga, Belgian Congo[6]. A series of sandstones and quartzites dipping 20° occurs here. One stratum has been prospected for its gold-platinum content. It is described as a quartzitic sandstone, 8.2 ft. thick, with a loose structure and a light-red color. In the decomposed part of the rock at the surface nuggets of gold weighing usually 0.03 to 0.15 oz., but occasionally up to 3 and 5 oz., were found. Shafts sunk 60 ft. disclosed the unaltered rock, in which the gold could be observed only as minute grains and plates, nuggets being exceptional, although one was found weighing 4.15 oz. It was partly native platinum. The following analysis gives the composition of the brown concentrate obtained in washing the sand. The variety and association of metals is unusual.

	%		%
Pb	29.55	P_2O_5	Trace
Cu	9.00	SiO_2	31.45
Fe	6.53	H_2O, O and loss	11.273
Ni	0.24	Pd	0.121
Co	1.02	Pt	0.002
Al	0.16	Au	0.032
CaO	Trace	Ag	0.062
V_2O_5	10.56		

The average for numerous samples was 0.26 oz. gold, 0.28 oz. platinum, and 0.05 oz. palladium per ton. Occasionally palladium was found in larger amount. Only traces of iridium were detected. The high percentage of vanadic oxide was believed due to the presence of descloizite (vanadate of lead) or psittacinite (a lead-copper vanadate), the latter having been discovered in the rock. Knopf mentions vanadium having been found on the Bill Nye claim two miles from the Boss mine, suggesting that cupro-descloizite is the mineral bearing it, but does not refer to it as occurring in the Boss mine ores.

(8) As recently described in the Mining and Scientific Press, chromium, platinum, iridium, and gold[7], together with other metals, have been detected in slate and greywacke of Silurian age in western Germany in the country lying to the east of Cologne and Düsseldorf. Krusch believes the platinum here to have come from the original basic rocks, the detritus of which supplied at least part of the sediments. The various determinations that have been made of platinum in these rocks are discordant, his own results ranging from a trace to 0.8 oz. per ton. He compares these old platinum-bearing sediments with the Ural placers and in explanation of the great vertical range of the platinum in the series believes that the higher members were formed from the detritus of parts of the earliest strata which were subjected to continued upheaval and erosion. Note should be made here of two possibly similar occurrences in the United States. They are given in Bulletin 585, 'Useful Minerals of the United States,' as follows. "North Carolina. A belt of platinum-bearing rock is reported extending from Cedar Falls, N. C., to Danville, Va." (No reference). "Pennsylvania. Cherokee and Laurens counties, platinum occurs in Cambrian grit." (No reference).

(9) A deposit of chromite in the basic edge of a granite in South Africa has been described as containing 1 dwt. platinum per ton of ore (28 to 45% Cr_2O_3)[8].

(10) It is well known that platinum was obtained both native and as the arsenide, sperrylite, in the copper ore of the New Rambler mine in south-east Wyoming. This ore is composed chiefly of chalcopyrite with pyrite, and secondary covellite and copper ores. There is a low content of nickel.

None of the cases enumerated have been productive, with the single exception of the last mentioned. They will serve, however, as already remarked, to indicate in some measure what are the favorable conditions for the concentration of platinum in other deposits than placers and igneous ores. It is noteworthy that in its igneous associations, as in the Urals and at Sudbury, and in the placers resulting in the former case, only traces of palladium accompany the platinum, whereas in the contact deposits and at the New Rambler and Boss mines, palladium predominates. Iridium appears to behave in the reverse manner, being relatively abundant in the crude platinum from the Urals and in the copper ores from Sudbury, while it is not mentioned, or is present only in traces, in the other kinds of deposits. It was noted in the German greywacke, example No. 8, while palladium was presumably not detected at all, which supports the theory of origin given. On the same grounds, the platinum in example No. 7 must have had a different origin from that in example No. 8, being akin in this respect to the lode and contact deposits.

Chemically, platinum is relatively inert like gold, and one naturally associates these two precious metals. But their chemical properties are by no means parallel. A discussion of gold and the platinum metals from this and a geological point of view would render possible deductions regarding the conditions that most favor their concentration to form deposits, and would also indicate their relative differences. In the discovery of new forms of ore deposits, however, the prospector and the miner are usually the real pioneers; and of those who follow none are more astonished at the new, or it may be 'impossible,' phenomena than the geologist and chemist.

Charles Butters and the New Metallurgy

AN INTERVIEW. By T. A. RICKARD

The actions of some people are significant. They have the faculty of anticipating next year's almanac. Charles Butters is an engineer whom I have always credited with a kind of technical prescience, a keen sensibility for the metallurgical requirements of tomorrow. His career is full of episodes that confirm this friendly guess of mine. Just now we appear to be about to make a critical turn in metallurgical advance. He is my neighbor. Why not ask him to express his views in writing, more particularly as he is conducting experiments on the very process that threatens to revolutionize the treatment of ores, as MacArthur's cyanide process did 25 years ago. But, like other men of alert mind and fluent speech, he dislikes to write. He cannot be persuaded to prepare an article.

THE APPROACH TO THE BUTTERS LABORATORY.

Well, if not in that way, then in another way it is possible to elicit valuable information. I asked him to submit to an interview—a friendly interview—by one who appreciated his useful work and desired greatly to give the benefit of it to the profession of which he is a distinguished leader. He yielded to my importunity.

You were born in California?

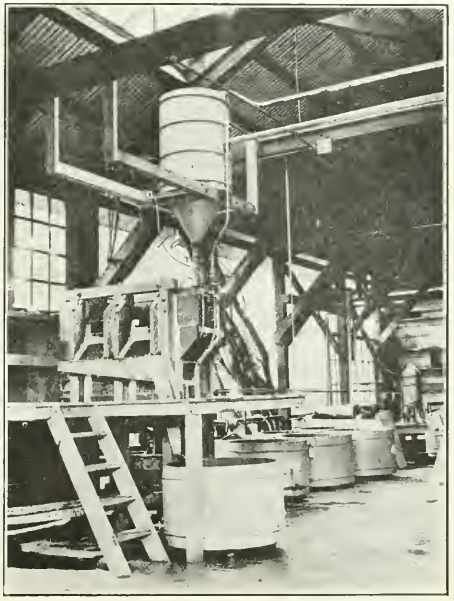
No; I was born at Haverhill, Massachusetts, in 1854 and came out to California when 10 years old. My father brought me. He was a leather manufacturer, but immediately after arrival here he started mining in Placer county. He was over 50 then and really was too old to go into a new business.

You seem to have inherited his initiative. You graduated at the University of California, didn't you?

Yes, in 1879. After graduation I went to New Almaden, in Santa Clara county, as chemist to the New Almaden Quicksilver Mining Co. But I was not long there. Getting a better offer from my brother Henry, I left California and went to Fairplay, in Colorado, where I established an engineering (that is, surveying and assaying) office with William H. Leffingwell, a class-mate of mine at the university. But our partnership was short-lived, because I saw an abandoned gold mill of which I thought I could make a success.

What happened?

I fitted up the mill and treated 30 tons—and went broke. That's the way to learn. Then I obtained a position as assayer and metallurgist in a silver mill in Frying Pan gulch, just outside of Leadville.



FLOTATION PLANT IN THE BUTTERS LABORATORY.

The accompanying photograph shows the Minerals Separation unit. The tanks are on little trucks, for convenience in moving. Crushing is done by a Krupp dry ball-mill and a small Hardinge conical tube-mill. Four laboratory tube-mills have been made out of 16-in. pipe, using steel balls to do the grinding. A Dorr classifier, and centrifugal pumps for elevating, are included in the testing plant. Also a complete vacuum-filter equipment. A bigger Minerals Separation plant and an equivalent Callow apparatus are about to be added.

When was that?

In 1881. Having treated 30 tons of ore in my own mill and gone broke in the attempt, I thought I knew enough to run the other fellow's mill. But in the interval I had visited every silver mill there was in Colorado and studied their methods carefully.

So you succeeded this time?

Yes. I remember that David Brunton visited me at that time and complimented me on my work. The firm of Taylor & Brunton was of great help to me; both partners were thoroughly informed concerning the metallurgy of silver, and they were very kind to me.

How long were you at Leadville?

About a year and a half. Then I went to the Holy Cross district and started a 20-stamp gold mill with plain amalgamation. From there I went to New York as agent for a San Francisco firm, the Pacific Iron Works. That was in the latter part of 1882. I didn't like the work at all; I was a metallurgist, not a salesman. However, I made the acquaintance of a lot of useful people. I made it my business to know all the mining engineers and people connected with the mining business. I can say that I always made it a point in my youth to make the acquaintance of the ablest men in my profession and I preferred to work for them at a comparatively small salary, rather than work for the non-technical public. I was criticized by some of my friends, who said that I could never make any money in that way, but the result of this policy was that I found myself working for Stetefeldt, Clarence King, Stephen Krom (who invented the rolls), Fraser & Chalmers, R. P. Rothwell, and Walter McDermott. McDermott was specially kind to me and put me onto the San Sebastian mine, of which I will tell you shortly. William Frecheville was another good friend; he was then in North Carolina, and employed me in expert work, that is, ore treatment.

So you left New York soon?

Yes, and went back to Colorado, where I started a silver mill, a custom plant, at Crested Butte, for a New York company.

What mill was it?

It belonged to Commodore Webb of New York and treated ore from the Ruby Silver and other mines. I worked all the ores in the district by dry crushing in a stamp-battery, roasting in Bruckner furnaces, and amalgamating in pans.

The crushing dry under stamps was tough?

Awful. No crushing capacity and no end of dust.

How long did that last?

About a year. Then I returned to New York and opened an office on my own account. That was in 1883. I shared a laboratory with Krom. We did general metallurgical work. I found a process for treating the San Sebastian ore.

What was the difficulty?

You could not amalgamate it. If you tried to concentrate, you lost about 80% of the gold with the slime. This was due to the combination of the gold with tellurium, which also was combined with the copper, as the mineral rickardite—a fact that we discovered in later years. The ore also contained molybdenite.

How did you solve it?

I found it could be readily treated by chlorination. I treated 5 tons in New York and then made a contract to build a mill for the company.

Where did you get your experience in chlorination?

A few months before I had made a honeymoon trip to North Carolina and taken charge of the Designolle reduction works, belonging to P. Bechet et Cie., a French banking firm. At that custom mill they bought various concentrates and roasted them, then the roasted concentrate underwent amalgamation with mercuric chloride in barrels. It was a wretched failure. The company failed and left me strapped. All that I had on hand was 20 tons of residue in the form of roasted concentrate running a little over $15 per ton. In order to get back to New York with my wife and mother, I had to find a method of extracting that $300 worth of gold.

What did you do?

I commenced to experiment in the laboratory by aid of a glass funnel and one pound of the roasted ore. By saturating the ore with chlorine gas, after a couple of days I extracted the gold out of that pound of ore. Thereupon I took 100 lb. and contrived a generator, attempting to treat it in the half of a small oil-barrel. After two weeks of vain effort I found that I could not saturate the stuff with chlorine gas. Finally I ascertained that the roasting previously done in the mill had been most imperfect. Thus, by experimenting on the 100 lb. of residue, I ascertained the absolute necessity of a dead sweet roast. At once I re-roasted the 20 tons and by the aid of 8 oil-barrels I built a little chlorination plant. In the end I had 100 slugs each representing $3 in gold. I sold some of them at the Charlotte mint and thus got enough money to pay for the journey to New York and make a fresh start. After that I was a chlorination expert. When the San Sebastian ore came to me, I was ready to apply chlorination.

So you went then to Salvador?

Yes; and built a 30-ton chlorination plant, which was entirely successful. They paid me $1000 per month. I was then 31. I remained 2½ years.

Then?

I returned to California and went to Kennett, in Shasta county, where I established a chlorination plant. That was in 1887. We extracted gold, silver, and copper. We received ores from distant localities, such as Grass Valley; for instance, from the Coleman brothers, who controlled the Idaho mine.

Was that enterprise successful?

Yes, metallurgically. I treated some most difficult ores, but I could not get enough business, so it was a hard pull. Incidentally, I treated several hundred tons of wet raw tailing running $4 or $5 in gold with a very slight impregnation of chlorine gas and obtained an almost complete extraction. After I had been there about two years and spent all my money and my plant had been seized by the sheriff—but I got out of that—Huntington & Hopkins protected me till I was on my feet again.

It was about time for another migration, was it not?

You have guessed right. At the end of 1889 Professor Christy appeared suddenly one morning as I was laying pipe in a ditch, in the rain. He told me that he had received a cablegram from Henry C. Perkins, asking for a man to go to South Africa. The qualification specified was that the man was one that owned his own reduction works.

You agreed to go?

Instantly; without a second thought. I felt perfectly competent to do the work. My wife and I proceeded to Johannesburg by way of London.

ical establishment. We bought all kinds of by-products. I was managing director for 5 years.

When did you first come in touch with the cyanide process?

At the end of 1890, nearly a year after my arrival at Johannesburg. The Cassel people had just completed a local plant to treat 1600 tons per month of stamp-mill tailing.

You studied that?

Certainly. I watched it most suspiciously. But when the clean-up was made, at the end of the first month, I was absolutely satisfied that the cyanide process was the

THE DEVISADERO MILL, IN SALVADOR.

There you built the chlorination plant at the Robinson?

Yes. I was assistant to Hennen Jennings, who was consulting engineer to H. Eckstein & Co. It was on Jennings's initiative that Perkins had cabled to Christy.

This plant was successful?

The Robinson chlorination mill was successful from the very start. I had the pleasure of making the first bar of gold produced by the chlorination process in South Africa.

You remained there some time?

Yes; I ran that plant until 1894, when I resigned and organized the Rand Central Ore Reduction Company.

On your own account?

Largely; this was a custom chlorination and cyanidation plant, with a refinery—it was a general metallurg-

most wonderful I had ever seen. I realized that it would kill chlorination and revolutionize metallurgical practice on the Rand. Immediately I hastened to urge the Ecksteins to buy the rights to the process in South Africa.

What happened?

They thought I was too quick in my judgment. Shortly afterward the owners of the patents realized the importance of the process and it could not be bought at any price.

Therefore, I suppose, you used cyanidation yourself in the big custom plant you built in the Central Rand?

Yes; immediately after Jennings realized what cyanide meant, he ordered me to design a plant to treat the entire Robinson output. At that time the Robinson had 40 stamps.

You designed that cyanide plant also?

Yes; and to show what metallurgical progress meant to the Robinson I can say that the mill was producing 4000 ounces of gold at the commencement of 1890, while in 1892 the mill was producing 8000 ounces and the chlorination plant 8000 more.

How were chlorination and cyanidation combined?

We concentrated the gold-bearing pyrite on Frue vanners, getting a 5-oz. concentrate, which was treated in the chlorination plant, while the residue was delivered to the cyanide annex.

So cyanidation was only applied to the residue?

At that time. Of course, a few years later the concentration of the pyrite was stopped and everything cyanided, after finer crushing.

How long were you on the Rand?

About 8 years. Then I returned to America, bought the San Sebastian mine, and organized the firm of Charles Butters & Co., Ltd., in London.

You had kept in touch with the San Sebastian?

Through all those years. I believed it to be a great property that had been grossly mismanaged. In association with David J. Pullinger, of Johannesburg, I paid $100,000 for it and within a year had $1,000,000 worth of 3-oz. gold ore in reserve.

What has it done since?

It has produced over $10,000,000, half of which has been distributed in dividends.

Did you remain long in Salvador?

I stayed there less than a year the first time, getting the enterprise fairly started. We erected a cyanide plant first to treat 20, then 40 tons, per day, increasing the capacity finally to 120 tons per day.

What was your next metallurgical departure?

I went to Mexico and established a cyanide plant at Minas Prietas, in Sonora. This was built to treat the dumps and the tailing from an amalgamation mill belonging to the Grand Central mine.

Was there anything special about that plant?

It was the first in Mexico to treat slime by agitation and cyanide. From there my assistants, E. M. Hamilton and C. G. Patterson, went to Guanajuato, to erect a similar plant.

When did you develop your vacuum-filter?

Soon after the Prietas mill was finished—in 1901—I built a slime-plant at Virginia City, to treat the old Comstock dumps. This material was a sticky stuff, much oxidized, colloidal, very tenacious, and hard to settle. I made a complete fizzle of the job at first, losing $100,000 in the first year. Altogether we lost $475,000, which was the price for learning how to filter slime. I developed my system of filtration, and in doing so I was assisted particularly by Mr. Patterson. Since then he has erected a number of similar plants in South Africa. As a sequel to our experience at Virginia City, all the Tonopah plants, particularly the Tonopah mill at Miller's, were designed. This was done in 1907 after we had treated 50,000 tons of their ore at Virginia City.

Eventually your work brought you into conflict with the Moore patents?

Yes, unfortunately. The courts gave an adverse decision in 1911.

Whereupon you turned your attention to a new field of research?

I continued research into the physical condition of slime. To obtain the latest information, I went to Germany, on the suggestion of my friend, Mr. H. L. Sulman, of London, and interviewed the great specialist in colloidal chemistry, Dr. G. Bredig of Karlsruhe. I arranged with him for a series of investigations into the physical characteristics of metallurgical slime. But the War stopped that.

When did you become interested in concentration by flotation with oil?

In 1899, as soon as I heard of Elmore's first work with this process in Wales, I went down there to see it and became sufficiently interested to make a contract with him to introduce flotation into the United States and Mexico. I have here now the first flotation plant made in the United States. It used to be in the basement of the Dooly building at Salt Lake City and consists of a cylindrical mixer with a centrifugal machine to separate the excess oil from the concentrate. That process was really 'oil flotation'—the floating of the sulphide mineral in an excess of oil on the top of the pulp.

Why did you drop it?

I could get no better results than by ordinary water concentration.

On what ores did you try it?

Anaconda ore and slime, also various copper ores from Bingham. We did not understand oiling at that time—this was 15 years ago—nor did we appreciate the necessity for making a froth. The excess of oil we used—20 lb. per ton of ore—made a fearful mess.

It did not attract you then?

It was impracticable in the form then adopted.

What did you do next?

In June 1914 I engaged the firm of Sulman & Picard to do some experimental work for me on the application of flotation to residues from the Nipissing mill, at Cobalt. The results were so startling that, at the first opportunity, I got into touch with the Minerals Separation company with a view to making systematic tests with flotation on the ores of various mines in which I am interested, such as the San Sebastian and Devisadero in Salvador, the Copala in Mexico, and so forth.

You returned to California?

Yes, I came to San Francisco and worked for a month in the laboratory of Mr. E. H. Nutter, the representative here of the Minerals Separation company. I perceived at once that the field of experimentation was very wide, so I arranged with Mr. Nutter for the loan of one of his company experts, Mr. F. A. Beauchamp, and established

a flotation department in my home laboratory here at Berkeley.

You have obtained interesting results?

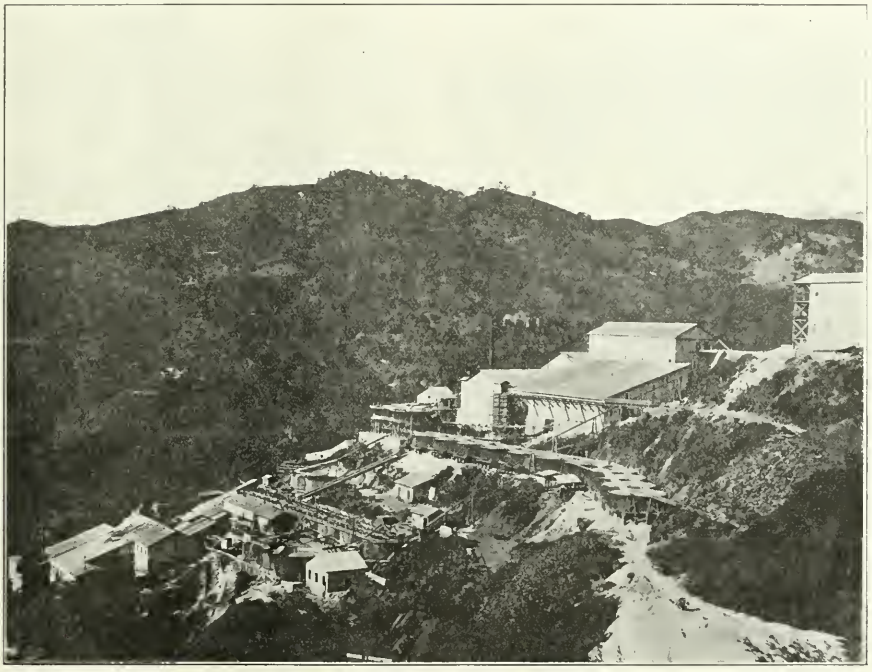
Since we started we have made determinations on ores from widely separated mining regions. At the start these tests were made on 500 grams, and yielded remarkable results. But tests on pound samples did not satisfy me, so we built a machine to treat 10 to 15 lb. From that we proceeded to make an apparatus capable of treating lots of any size. We are about to make considerable additions to our flotation plant.

That is an important fact.

Yes; as you have often said, "The failures are as interesting as the successes." We shall be prepared to give you full particulars for publication. Mr. J. E. Clennell has made a great number of tests and the description of his work will prove useful to the profession, I feel sure.

Can you produce a richer product by flotation than by water concentration?

In all our work, the first thing we aim to obtain is a rich concentrate and a residue that can be discarded.



THE COPALA MILL, IN SINALOA, MEXICO.

How much oil do you use?

In our experiments we have been using from $\frac{1}{2}$ to $1\frac{1}{2}$ lb. per ton of ore.

How much acid?

None. We work in an alkaline solution.

Did you experiment on the subsequent treatment of your product, namely, the concentrate from flotation?

Of course. To our complete surprise we found ourselves unable to cyanide the concentrate produced by flotation. If this product can be shipped to a smelter, it is a simple matter, but in many cases it is imperative that the concentrate be treated on the spot. Evidently, if it be the oil that prevents cyanidation, we might produce the concentrate by the use of soluble oils in the flotation process, but, so far as our results go, the class of oil that produces the cleanest concentrate is just the one that we are unable to dissolve.

When this can be done, the treatment of a gold and silver ore is tremendously simplified.

You have done this in some cases?

We can do it on a silver ore, if it is not too much oxidized. Even on surface ores some of our results are surprisingly good. For instance, take the old dumps that have been mined, milled, and re-concentrated at Virginia City for the last 30 years. We can get a high-grade concentrate and a comparatively low residue even on this material; that is, we can take material assaying $5 per ton and impoverish it down to $1.50 per ton while getting a $170 concentrate. But even this will not compete with cyanidation, because I cannot treat that concentrate. I can ship it to the smelter, but the freight and smelter charges, plus the $1.50 in the residue, represent something like $16.50 as against the 75 cents per ton lost in the cyanide tailing.

How about Mexican silver ores?

On ores such as those of Copala, in Sinaloa, I can obtain a high-grade concentrate, even from the dumps. For instance, on what we call the *colorada manta* the results are:

	Gold, oz. per ton.	Silver, oz per ton.
Original ore	0.10	10.10
Concentrate	0.84	198.48
Tailing	0.01	0.15

One would think that as this ore is almost completely oxidized it would give trouble, but the silver has been left in such a condition that it can be floated, probably as argentite.

You get better results on sulphide ore?

Naturally, when unoxidized the ore presents no difficulty. For example, a sample from the dump at the San Carlos adit at Copala gave these results:

	Gold, oz.	Silver, oz.
Original ore	0.11	15.60
Concentrate	3.58	468.14
Tailing	0.02	1.48

Then flotation promises to have a wide application?

One cannot say that it is a panacea for all kinds of metallurgical troubles, but it is a process that every metallurgist must learn, because if he does not ascertain whether there is a place for it in his flow-sheet he will be missing big chances.

But the difficulty of treating the flotation concentrate?

On a gold concentrate like that from San Sebastian ore we can get a high extraction by cyanide, after roasting, but where both silver and gold are present our results are poor. Take, for example, the roasting tests on flotation concentrate from Virginia City, assaying 2 oz. gold and 182.44 oz. silver, we obtained these results:

Treatment.	Gold, %	Silver, %
1. Oxidizing roast, following by sulphuric acid wash, then cyanidation	90.5	19.7
2. Plain oxidizing roast, without acid wash, then cyanidation	75.5	6.7
3. Oxidizing roast, followed by chloridizing (5% salt) roast, then cyanidation	80.5	75.6
4. Raw cyaniding	35	5.75
5. Following this with a chloridizing roast, and further cyanidation, we obtained additional	13	23.45
Thus by 4 and 5 combined	48	29.2

The metallurgical treatment of flotation concentrate is an entirely new subject.

Is it not a question of eliminating the oil in the concentrate?

I do not know.

Is it not possible to find a solvent for the oil?

I should say that it might be easier to use an oil we could dissolve than it would be to find a solvent for the oils we use, but, as I have already stated, up to the present, the best results are obtained with insoluble oils consisting essentially of tar products.

Is that because the insoluble oil gives you stronger bubbles in the froth?

Yes, the insoluble oils are better collectors of the sulphide mineral; such oil is added just to give the froth sufficient volume to constitute a convenient vehicle for the removal of the oiled mineral.

Do you apply flotation to the tailing or to the crude ore of San Sebastian, for instance?

Our average residue at San Sebastian after cyaniding is $2.16 per ton. We can reduce that by flotation to 20c. per ton and obtain a concentrate assaying $7 to $18 per ton, depending upon the part of the mine from which the ore comes. The ore itself can be subjected to flotation so as to yield a tailing assaying from 75c. to $1 per ton, on an original ore assaying $20 per ton.

So that, if you knew how to extract the precious metals in your flotation concentrate, you would proceed to use flotation before cyanidation?

With cyanide we get a residue of about $2 per ton. In our flotation tests we obtain an extraction of 95% at once, leaving a tailing containing $1 per ton. We find that by roasting at a temperature not to exceed 500°–600°C. the copper is left as a sulphate. By washing thoroughly with water, we extract 10 lb. copper per ton and then reduce the flotation concentrate by cyanidation from $100 to $1 per ton.

Does the question of cost arise?

We figure that we would gain about $2 profit per ton by using flotation as described.

How about the chemicals required?

We would use about ½ lb. oil per ton, as against 5 lb. cyanide. We would have to use cyanide for the treatment of the concentrate, but it would be only 2 lb. per ton and the concentration would be in the ratio of 4 to 1, that is, ½ lb. cyanide per ton of crude ore.

You have experimented on the ores of other mines besides your own?

Certainly, enough to indicate that every silver mill, at least, should ascertain whether flotation is applicable. For example, we tried the ore of another mine in Sinaloa. The results were:

	Gold, oz. per ton.	Silver, oz per ton.
Original ore	0.52	15.94
Concentrate	8.16	242.36
Tailing	0.035	2.07

These figures indicate that it would be possible to beneficiate an enormous quantity of low-grade ore not available hitherto for treatment, without additional capital expenditure for power.

I presume you have not decided what is the best type of mixing machine?

We realize the necessity for a most intimate mixing of oil and ore, after which quiescence is necessary in order that the bubbles may not be broken, thus facilitating a cleaner separation. It seems to me that the two stages of treatment should not take place in the same machine.

Do you prefer the pneumatic or the mechanical agitation?

All the work done in this laboratory up to date has been performed with the Minerals Separation machine. At present, with my limited knowledge of the process, I would say that mechanical agitation is best for the oiling stage, because it is more positive in its action. Mr. George O. Bradley was kind enough to show me a new positive oiling machine that he has devised; it impressed me as likely to prove effective. I believe that Mr. J. M. Callow's idea of separation in tank-like cells is sound. We are now installing a complete set of Callow apparatus. He has shown that mechanical mixing is not necessary in certain cases of copper ore, but the problems arising from the treatment of copper ores are quite different from those to which I have devoted myself. The proportion of mineral to be extracted from a gold and silver ore is extremely small as compared with that obtained from a copper ore. The froth required for the separation of precious-metal sulphides is more delicate and requires different handling.

As to the various oils?

During a recent visit to Salt Lake, Mr. R. C. Gemmell was kind enough to permit me to visit the Arthur plant, where I met Mr. F. G. Janney, Jr. Frankly, I was dumbfounded to see what a lot of work he had done on the subject. Mr. Janney has established a laboratory for the analysis of flotation oils and has records of over 500 oils already. This is work of supreme importance, for he is ascertaining what are the elements in the various oils that accomplish given results.

Some ores require an acid and others an alkaline treatment, do they not?

Undoubtedly some ores work better in an acid medium, but as I realized how much greater is the ease with which an alkaline solution can be handled in a mill, I have not rested content with any acid treatment. In every case we have worked out our results in an alkaline solution. In fact, if cyanidation is to follow flotation, I consider it essential to perform the flotation in an alkaline solution; but, you understand, I refer to gold and silver ores only, not copper ores.

Finally, Mr. Butters, you are much impressed with the importance of flotation?

Yes, indeed. I am convinced of the far-reaching importance of the process. It has started a new era in the concentration of ores.

QUARTZ-REEFING predominates in Victoria, so a report says. Translated into American this means that there are more quartz mines than placer mines in the State of Victoria, Australia. A considerable amount of gold is obtained from alluvial workings, both surface and deep leads. The deepest mines in Australia are found in the Bendigo district, where the two deepest shafts on December 31, 1914, were 4614 and 4318 ft. deep. In all, there were 53 shafts in this district more than 2000 ft. deep.

Electricity in Metallurgy

In summarizing their investigation of this subject, Dorsey A. Lyon and Robert M. Keeney, in Bulletin 104 of the A. I. M. E., make the following general conclusions:

1. The market for hydro-electric power for electro-metallurgical industries in general is not great; and under the best conditions the part consumed in electro-metallurgical plants would be a very small proportion of the total hydro-electric power that it is possible to develop in the Western States.

2. Although the outlook at the present time is not favorable to the establishment of extensive electro-metallurgical industries, we are nevertheless of the opinion that such industries will, in time, be established, but perhaps along other lines than at present, that is, other than the production of aluminum, ferro-alloys, pig-iron, steel, etc. It is also doubtless true that the electric furnace will in time be quite generally used for the local production of steel castings, but an extensive use of the electric furnace for this purpose will not involve any great consumption of electric power.

Therefore, if our analysis of the situation be correct, is it reasonable to expect that the hydro-electric power companies may ultimately be able to dispose of a great portion of their surplus power by reason of the development of new electro-metallurgical industries? We believe they will, and for this reason:

At the present time the metallurgy of the non-ferrous metals is rapidly changing. The processes which were suited to the treatment of non-ferrous ores five or ten years ago are at the present time not satisfactory, because the non-ferrous metallurgical plants of the country are called upon to treat ores of a lower grade, and also more complex than formerly. Such being the case, processes must be devised which will meet these requirements. However, we do not for a moment imagine that electro-thermic or electrolytic processes will prove to be the only solution of the many problems which are at the present time confronting the non-ferrous metallurgist. Although such processes may greatly assist in solving these problems, we are of the opinion that further research work will indicate other solutions. This is true, especially as regards hydro-metallurgical processes, because the profitable treatment of the low-grade and complex ores above mentioned requires the use of cheap reagents. Such being the case, the hydro-metallurgical treatment of such ores may bring about the establishment of an electro-chemical industry for the production of the necessary reagents and thus indirectly the metallurgical industry may bring about an extended use of hydro-electric power. Whether this will prove to be the case or not, remains to be seen. It can only be determined by a careful investigation of the subject, and by extensive research, having for its object the finding of new uses for electricity in metallurgical work.

A possible use for vast quantities of power may be found in the fixation of atmospheric nitrogen.

Mining in Utah

By L. O. HOWARD

Mining in Utah is fast returning to normal conditions. It might with more truth be said that it has passed the normal. With the Utah Copper Co. in a position to mine to the full capacity of its concentrating plants, copper production is again making records. With the favorable copper market, this company, one of the few to maintain its regular dividend during the depression following the beginning of the War, is making a large profit, which it has justly decided to share with its employees by means of increased wages. Details of the new scale have already appeared in the PRESS. Other companies are now following suit, so that miners and salaried men employed by the large producers are enjoying greater prosperity than for some time past.

Other business conditions being good locally, attention has been attracted to the mining industry, with the result that many small investors are putting a little money into mining prospects. As copper, lead, and zinc now command high prices, confidence in mining has been stimulated, with an effect that is far-reaching. In the districts, new or formerly dormant, such as Bull Valley, Big and Little Cottonwood, Saline, and many others, prospects are being developed with encouraging results. In the older districts leases are in demand and a general air of activity is manifest.

Lead-producers throughout the State have responded to the increased price of that metal. Production is now fully in keeping with past records in Park City, Tintic, Beaver, and Stockton.

At Park City, the four old operators, Silver King Coalition, Silver King Con., Daly West, and Daly-Judge, are producing progressively increasing tonnages. Tailing-dumps are being acquired for their zinc-content, the month just past marking the commencement of operations in the up-to-date mill on the large dumps at Atkinson, and the furtherance of plans in connection with the old Grasselli tailing at Park City, where the second mill of the Grasselli Chemical Co. has passed into other hands.

It is, however, necessary to record the cessation of operations at the chlorination plant of the Park City Mills Co. In my last article I mentioned the difficulty in gold extraction. On the American Flag ore, which has a high combined lime and magnesia content, it has been impossible to extract the gold commercially. Since gold is the principal metal in these ores, the failure is serious. Consumption of acid was excessive, and although the extraction of the base metals was satisfactory, a big excess of chlorine failed to dissolve the gold. Large amounts of bleaching powder and acid added to the charge in the vats evolved fume in such quantity that the men were driven from the work, yet upon circulating this solution the chlorine was consumed without appreciable benefit in the saving of the gold. There is too much copper in the ore for satisfactory work with cyanide, except at the expense of high consumption. Concentration has not appeared feasible to the owners, for the ore will not stand much expense. Experimentally an excellent extraction of copper and gold is possible by preliminary treatment with ammoniacal solutions, followed by cyanidation, but the consumption of these reagents has not been determined. It might also be remarked that preliminary experiments on presumably representative ore resulted in a recovery of fully 85% of the gold by chloridizing roasting, yet the process failed in commercial application.

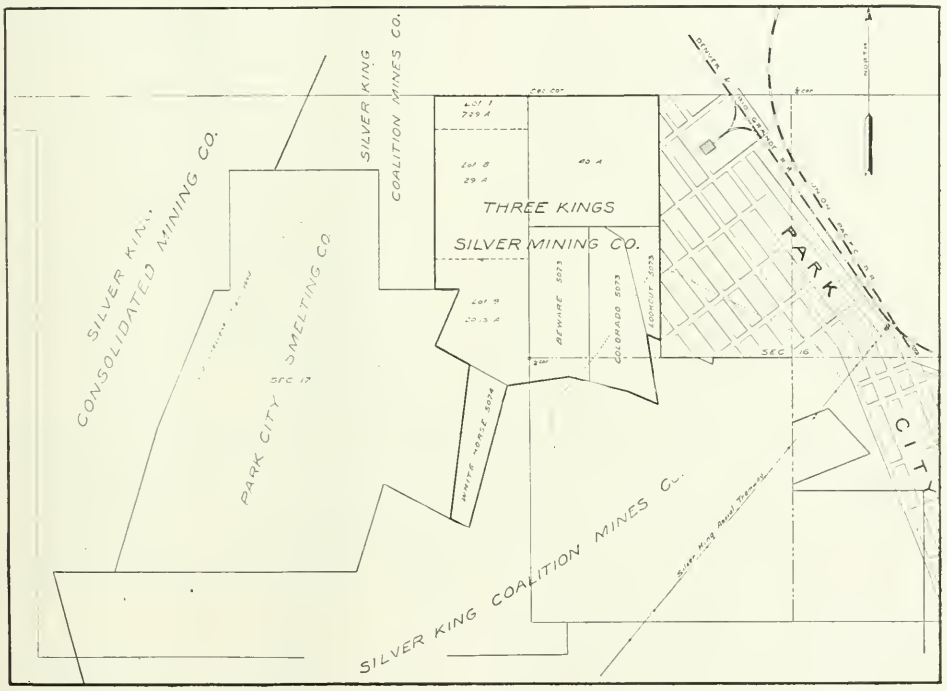
It is likely that further experiments will be undertaken. Pending a satisfactory settlement of the difficulties the mill is closed-down indefinitely. Of the three chlorination plants of much promise some months ago, none are now in operation.

A serious attempt to enlarge the boundaries of the Park City district is being made by the Three Kings Silver Mining Co., which is seeking ore farther north than any yet found in the district. For many years sporadic attempts have been made to do something with this ground—attempts that were thwarted by diverse ownership and lack of the necessary resources. When the control passed under one management, a two-compartment working shaft was started. This has now reached a depth of 530 ft. The bonanza horizon in the adjoining Silver King Coalition and Silver King Consolidated mines lies in the Park City lime formation, just above the Weber quartzite. While the other companies have had to sink 500 to 700 ft. to reach the Park City formation, which is itself about 800 ft. thick, the Three Kings has the advantage of starting in the Park City formation, and should therefore reach the Weber quartzite in another 200 to 275 ft. The company is well financed, work is being done in an efficient and conservative manner, and the results of this exploration should be of the greatest interest. Excluding management expenses, the officers giving their time gratis, the shaft has cost to date $35 per foot. Mining conditions are favorable, the haul to the railroad being but three-quarters of a mile, and the shaft but 180 ft. above the tracks.

The long and honorable record of the older lead districts has made their names famous outside the State. Among the less known districts is that of Stockton, nine miles from the station of the same name on the Salt Lake route, 41 miles west of Salt Lake City. Silver-lead and

zinc carbonates occur in the bedding-planes of a porous limestone, and at the intersections with numerous fissures. In view of the small amount of publicity this district has received, and the lack of information available except to those working there, some details of individual operations may be of interest. The district is one of the oldest in the State and has a substantial record. The recent favorable factors introduced into mining have led to much exploration and development. The Hidden Treasure mine is the largest producer. Twenty-five to 30 men are engaged, on company time and on leases; stopes, so that the development cost is nil. The thickness of the deposit varies from three to four feet.

Shipments are also being made from the Thad Stevens property, Utah Queen ground, and the Kirk lease on the Big Lead mine, the ore of which is characterized by an appreciable amount of gold. The Dry Canyon Con. is being developed by one or two men who have made occassional shipments from stringers cut in extending the main adit, which is now in over 4000 ft. The Wandering Jew is developed to the shipping stage and the Eureka-Ophir is being prepared for development.



MAP OF PART OF THE PARK CITY DISTRICT, UTAH.

shipments run as high as 1000 tons per month. Stoping is done with air-drills, and both lead and zinc carbonates are shipped.

On the Mono Development ground four sets of lessees, of four to seven men each, are working, all in silver-lead carbonate, shipping 250 tons per month. The ore is found on the bedding-planes of the lime and in intersecting fissures. A car recently sent to the Salt Lake market assayed 51 oz. silver and 12% lead; another assayed 30 oz. silver and 24% lead. These figures indicate the range in the amount of the principal metals. With the addition of power-drilling equipment the output will be greatly increased.

At the Queen of the Hills mine 25 men are working. Shipments of ore assaying 41% zinc are being made. The output is estimated at 200 tons per month. This ore is cheaply mined. It lies on the foot-wall of old lead

While the older mines at Tintic, for example, have not obtained as much benefit as was anticipated from the high price for zinc, due in part to the low grade of their ores, new properties are being developed elsewhere to supply a good grade of carbonate ore. At Saline, three miles west of Promontory on the Southern Pacific cut-off west of Ogden, there is much activity in the search for zinc ore. The Lakeview mines have been well developed and a large tonnage is said to be exposed. The ore horizon here is also along the bedding-planes of a limestone, which dips at about 30° across a series of parallel ridges, on both sides of which ore can be traced. The principal showing is on the ridge covered by the Lakeview locations. Numerous openings at different elevations on both sides have shown that the ore continues for 3000 ft. along the strike. Assays indicate a zinc content averaging 35%. It is planned to ship at the rate

of 700 tons monthly. Thirty-five men are employed. In certain portions of the ore-horizon, there is said to be seven feet of high-grade lead ore on the foot-wall. Leases are being taken up rapidly and companies formed to explore the supposed continuation of the known ore-beds, and high hopes are entertained for the development of another base-metal district.

Operations at the radium mines in the southeastern part of the State have been paralyzed by the War. Some desultory development has been undertaken but there are scores of claims on which assessment work is not being done, the situation appearing hopeless to many operators, so that only the very best ground is protected. Had the interference of the Government in the radium business not deterred capital from building other extraction plants it is possible that other markets would have been created for these ores, and the smaller operators—outside the two large interests that have their own reduction plants—would not have been entirely dependent on the foreign markets that have now been cut off by the War. The action of the Government, while in no way providing for the sale of the ores of producers not affiliated with the Bureau of Mines, has prevented others from buying them.

As compensation for the paralysis of this promising industry the War has undoubtedly accelerated the development of the potash deposits at Marysvale. At the property of the Mineral Products Co. 150 men are rushing work on the aerial tramway and mill. This plant is to have a capacity of 100 tons per day, and is being erected in the foot-hills of the Sevier range six miles south-west of Marysvale and four miles from the mine. A tramway to extend one and a half miles from the mine to a place where ore can be loaded by teams, is being erected rapidly. The alunite deposit is at a high altitude, 9000 to 11,000 ft., and in one mile the tramway has a difference in elevation of 2000 ft. The principal difficulty in construction is in getting materials on the ground, but every device that ingenuity can suggest is being used to insure the completion of the tramway before September 15, and it is confidently expected that the first commercial production of potash in Utah will begin then.

While the revised figures of the U. S. Geological Survey show a decline in 1914 in the production of all metals in Utah except lead, the dividend payments for the first seven months of 1915, including disbursements of all mining companies making public reports, aggregate $4,050,000, compared with $3,410,000 for the same period in 1914, indicating a much better position in the present year.

When negotiations have been in progress for the purchase or annexation of new territory by the United States, one of the strong arguments for its acquisition has been the presence of valuable mines. This was the case as regards the Louisiana Purchase and the annexation of California. The possession of mines is desired by all nations and mining territory is often fought over—witness Galicia.

How Not to Build a Smelter

Some of the peculiarities of the Salida smelter as originally built should serve to prevent the younger men from making similar mistakes; the older men can get their satisfaction by reflecting that they never did anything quite so far removed from good practice.

Originally, a brick wall, with a narrow door in front of each blast-furnace, was constructed. How the work was to be done behind this wall is not known, but it shows that the designer did not know how to do the work.

The water jackets were held in place by a 12-in. I-beam running the length of the furnace, thus effectually preventing any one from examining a tuyère or jacket.

The shaft-walls on the feed floor were so thick that the feeders were shoving ore into one end of a tunnel, and, since the opening was not as wide as the shaft, the ends of the furnace could not be fed except by throwing the charge around a corner—which, of course, was not done.

The proposal to concentrate matte, carrying 20% lead and 5% copper, in a copper-matting furnace was intended to do away with the necessity of roasting equipment.

The largest Corliss engine on the plant was the exhibition engine at one of our world's fairs, held some years ago. When repairs were needed, it was discovered that this was the only engine of the kind ever built, and the drawings of it were lost; so each repair part called for an accurate drawing.

In the track plan of the works, all the ore, coke, and limestone had to be unloaded from one track. This track also held the cars which were to be unloaded at the oxide crusher as well as at the sulphide mill. The problem of dispersing some of this congestion was not simple. It was solved by building two trestles in place of one; by having the limestone brought in dump cars so that unloading took little time; and by building an oxide-crushing and screening plant on new tracks.—F. D. Weeks in *Trans.* A. I. M. E.

Marketed production of natural gas in the states of New York, Pennsylvania, West Virginia, Ohio, and Kentucky in 1914, amounted to 425,871,728,000 cu. ft., having a total value at the point of consumption of $73,677,641, or an average of 17.3c. per 1000 ft. according to statistics compiled under the supervision of J. D. Northrop of the U. S. Geological Survey. Compared with 1913 the output of natural gas credited to these states shows a slight increase, amounting to 608,480,000 cu. ft., less than 0.2%, whereas the value of the production shows a substantial gain, amounting to $4,359,537, or a 6% increase.

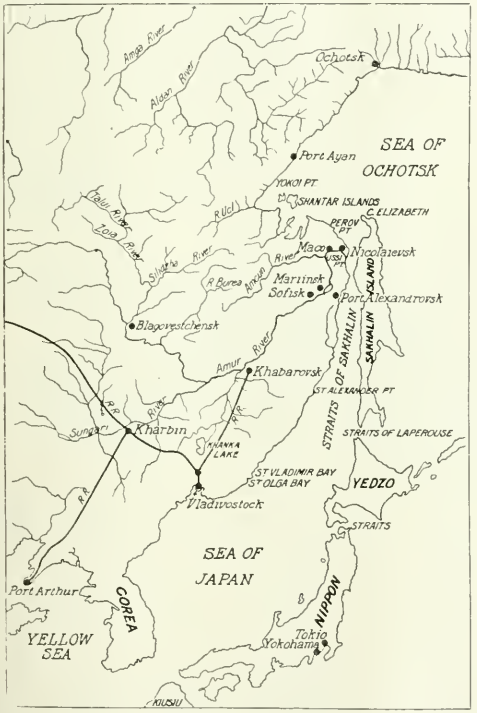
Gold was known in Australia prior to Hargraves' memorable discovery in 1851. But it was the news of the sensational finds in 1851 and 1852 that brought about a constant stream of immigration, and caused an increase of population from 221,000 at the end of 1841 to upward of 1,168,000 at the end of 1861 and which, as one writer aptly phrases it, "precipitated Australia into nationhood."

Dredging on the Amur

By K. I. HLEBNIKOFF

The first, and only, dredge to go to work in the Amur region is the one operated by the Amur Gold Mining Co. It is on the Kharga, a stream that empties into the river Selemdja, a tributary of the Zeya, which, in turn, feeds the great Amur river, the confluence being the town of Blagovestchensk, the residence of the Governor of the Amur territory and the point of export for the gold of Eastern Asiatic Russia.

This region is characterized by ancient sedimentary strata and old intrusive igneous masses, the predominant



rocks being micaceous and hornblendic gneisses. Owing to the excessively wet climate of the country, oxidation has penetrated deeply, especially where the river Zeya with its tributaries has cut through these gneissoid masses and distributed the products of erosion as gravel in the river-beds. The greater part of these rich placers has been worked by natives with the crudest methods, but much of the gravel has not been touched as yet. The fragmentary reports of the Amur Gold Mining Co. show, however, what can be done in this region by dredging.

The dredge was purchased from the Werf Conrad company at Haarlem, in Holland; the capacity of the bucket is 5 cubic feet. The steel pontoon, and all the requirements for the dredge, weighing altogether 505 tons, cost $55,000, including transportation to Blagovestchensk, Eastern Siberia. The machinery was then carried, in the summer of 1913, by steamers on the Zeya to the Norsk factory; then, in winter, from this factory, it was carried on sleighs, along the frozen surface of the Selemdja river, for about 245 miles, to the Zlatuostovsky placer, on the Kharga, at a further cost of $35,000. The various items of expenditure were:

Cost of plant delivered at Blagovestchensk	$55,000
Transport thence to the dredging ground	35,000
Putting the parts of the dredge together in place	10,500
Equipment of the machine-shop	6,000
Building of the new settlement	9,000
Total cost of the dredge and buildings	$115,500

The erection of the dredge was started on January 25 and was finished on the last day of May 1914. Actual dredging started on June 15 and finished on October 15, 1914. During all this time work of dredging proceeded in the bed of the stream and partly along the rims of the same. The following figures show what was done.

Working days	104
Days lost on account of the high water, breakages, etc.	27
Total working hours	2,498
Cubic yardage treated	158,521
Daily average yardage	1,500
Average dredging time daily	19 hr. 49 min.
Average value per cu. yd.	75c.
Ounces of gold recovered	7,554
Value of gold recovered	$120,199
One ounce of gold in Russia is worth	$15.90

To the cost of the dredge should be added the sum of about $22,000 for maintenance during the winter, also fuel, and different repairs preparatory to starting on the second annual campaign, in the spring of 1915.

The grand total cost, therefore is	$137,000
The total gold recovery is	120,199
Showing a loss of	$16,801

The dredge is in operation this summer and naturally will work to better profit than in the preceding year, as there will be no more of the first high costs of purchase and equipment. The dredge is of the New Zealand type.

Filing systems for papers should provide for: (a) Certainty of obtaining a particular paper or of obtaining all the papers relating to a particular subject; and this certainty to be independent of the time that has elapsed since the filing of the paper. (b) Rapidity of obtaining a particular paper or of obtaining all papers relating to a particular subject; and this rapidity to be only slightly affected by the time which has elapsed since filing. (c) Rapidity with which the documents may be filed. (d) Cheapness of operating the system. (e) Simplicity. (f) Reduction to a minimum of the space required for documents. (g) Miscellaneous requirements and desirable features such as numbering, cross-filing, and so forth.

Dycrasite, a silver antimonide, has been found in masses up to one ton weight in the Broken Hill lodes, New South Wales.

Treatment in the West End Mill

During the year 1914, the West End stamp-mill and cyanide-plant, at Tonopah, Nevada, treated 65,351 tons of ore, according to the metallurgist, Jay A. Carpenter, whose report was written recently. The ore averaged $14.02 per ton. An extraction of 89.9% resulted in 11,709 oz. gold and 1,073,241 oz. silver being recovered. This includes company and custom ores. The extraction was a little lower than in 1913, due to the low recovery made on the amalgamation tailing. The mine ore yielded 90.9%; amalgamation tailing, 71.8%; and sand-tailing, 66.66% gross. An average of 25.4 stamps dropped continuously, with a duty of 7.05 tons per day. The direct cost of ore treatment was $2.768 per ton, as follows:

Labor, at an average of $4.50 per shift	$0.724
Power, at 1.45c. per kw. hour	0.506
Sodium cyanide, 2.83 lb.	0.600
Water, 246 gal.	0.185
Cut zinc, 1.34 lb.	0.126
Pebbles, 6.05 lb.	0.105
Fuel-oil, 3.1 gal.	0.121
Shoes and dies	0.026
Tube-mill liners and supplies	0.050
Lime, 2.95 lb.	0.033
Lead acetate, 0.43 lb.	0.037
Other supplies	0.255
Total	$2.768

The following changes in mill-practice are of interest, not only for the saving in cost and extraction, but also as an illustration of the spirit actuating the organization.

The trial of the Komata lining in two of the three tube-mills has shown a good reduction in cost of liners per ton of ore ground. Also, the trial of artificially rounded flints from Manhattan, as a substitute for the Danish pebble in the tube-mills, indicates that a good saving will be made in the cost of pebbles. In the closed tube-mill circuit in the new 10-stamp addition, a screw-conveyor was placed at the sand discharge of the Dorr classifier to carry the sand to the small diameter tube-mill scoop, instead of installing the heavy unbalanced scoop as in former practice. This new design has given excellent results and has been adopted at other mills.

The concentrating department has been handled strictly as an adjunct to cyaniding. For over five months, while the mill was treating a large daily tonnage of $17 ore, the concentrate from the 12 Deister slime-tables was re-concentrated on a Wilfley for shipment down to 0.5% of the ore tonnage, but still containing 14% of the total metal-contents. The removal of this proportion in concentrate reduced the value of the ore entering the agitation department to a point where the length of agitation obtainable made a high total extraction. With a decrease in the grade of the ore in May, the concentrate from the Deister table was pumped back to the tube-mills, making a closed circuit. This method of holding the concentrate back for additional grinding and treatment until it was so finely ground that it escaped with the rest of the pulp to the agitation department, resulted in as great a percentage of extraction ahead of the agitators as in the previous method of concentrate shipment. While the final gross extraction was not as great, the reduction in the marketing cost from 2.6 to 1.6%, gave a higher net extraction. With the reduction to 20 stamps in November, concentration was discontinued, since the ore with longer agitation and finer grinding gave as high gross recovery.

The plan of settling the thin Callow cone-overflow pulp separately from the table-tailing by taking it direct to a Trent agitator, the top four feet of which was used as a settler, while the remaining 14 ft. was agitating thickened pulp, proved very successful and saved additional thickener-capacity for the increase in tonnage, due to 30 stamps.

The Carpenter type of Trent agitator, placed in commission in October 1913, proved so successful that all six agitators have been changed to this style. The only parts subject to wear in the present submerged bearing are a pair of extra heavy pipe-nipples, but the original pair are still in fair condition after 15 months' service. It is now five months since the last agitator was installed and there has not been the trouble of emptying an agitator, and there is no indication that it will be necessary for months to come.

By careful attention to the valves, leaves, and manipulation of the filters during the year, a new low record was made in December of 5.12c. soluble loss per ton of ore in the filter-discharge stream.

The installation of a Tetrault two-stamp battery and concentrating table, both made at the local foundry, has given a neat and efficient method of concentrating the shot silver and matte from the refinery slag.

The United States Steel Corporation has resumed construction work on its steel plant at Duluth. This work was interrupted because of unsettled conditions due to the War, but several hundred men are now working and the plant should be completed by January 1916. The plant will use but a small portion of the ore produced in the district tributary to Duluth and the steamers that carry ore to Cleveland and other lake ports will bring fuel as a return cargo. These are the first steel works to be established near the mines and to which the coal is brought to the ore instead of the usual procedure of carrying the ore to the coal. The market for this plant will be the territory to the west of Duluth, as far away as Montana, and the Canadian prairie towns.

A wrought iron pillar 16 in. in diameter and 23 ft. 8 in. long is one of the great curiosities of India. The method of its manufacture is unknown; even the date when it was made is uncertain and is variously estimated from 319 A.D. to 1052 A.D. The pillar now stands near the Kutub Minar tower a few miles from Delhi.

Arsenic production of the United States last year amounted to 4670 tons, valued at $313,147, an increase of 46 per cent.

Mining Conditions on the Witwatersrand

By W. L. HONNOLD*

GENERAL. †The Rand mines produced gold valued at $166,186,000 in 1914, or say 40% of the world's product. This gold came from 25,701,954 tons of ore; the average yield being about $6.47 per ton. The Rand mining conditions are unique, yet their magnitude renders them of great interest.

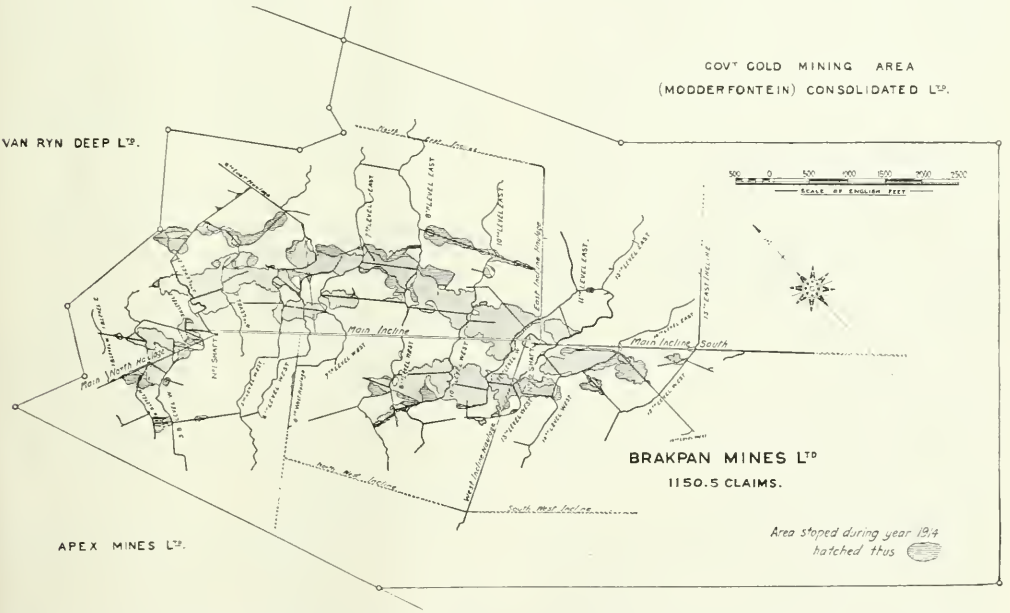
The principal mines are situated along the northern limit of an irregularly shaped geological basin, and extend in almost unbroken continuity over a distance of about 60 miles. As the boundaries are defined by vertical planes there are both 'outcrop' and 'deep-level' properties, all differing in size and in technical features.

Briefly, the ore deposits are profitably enriched portions of certain conglomerate beds, or 'reefs,' rarely more than three, which are interposed between quartzite, or quartzite and slate, and lie so closely together that where more than one are mined they are dealt with as a working unit, although they may be stoped separately. Their collective extension is locally referred to as 'the Reef.'

Along the outcrop the series dips more or less steeply, and in depth it flattens, the latter tendency being most marked in the Far East Rand, where the bottom of the basin is nowhere so deep as to be inaccessible.

Dikes and faults are a common feature throughout. They are, however, so well understood as seldom to involve mistaken procedure, although they may occasion delay and added expense.

The pebbles are mostly of rounded quartz, averaging perhaps less than an inch in diameter, cemented together by a fine-grained quartzitic matrix of metamorphic character. Sedimentary inconstancies, including partings of quartzite, are in evidence, and more or less pyrite is interspersed, which may or may not be appreciably auriferous. Native gold occurs in varying amount, constituting on the average perhaps more than half the assay value of the orebodies.



In my opinion "the average quantity of gold per unit of reef-area lessens in depth." The beds vary in thickness from a few inches to 10 ft., averaging 33 in. The uniformity of the Leader [one of the seams of gold-bearing banket or conglomerate] is remarkable; it has been stoped almost continuously for a length of five miles on the Central Rand and has been worked on the dip to about 7000 ft. from the outcrop. While in the Central Rand the Village Deep mine has reached a depth of 4600 ft. at a horizontal distance of 7000 ft. from the outcrop,

*Lately consulting engineer and managing director of the Brakpan and other mines in the Far East Rand.

†Abstract of a paper to be presented at a meeting of the American Institute of Mining Engineers, to be held in San Francisco, September 1915.

and the dip in the lower levels is nearly 40° with a steepening tendency, in the Far East Rand the Brakpan mine has only reached 4100 ft. 4 miles from the outcrop and the local dip is but 7°. The Springs mine 3½ miles from the Brakpan is 3750 ft. deep 7 miles from the outcrop; in this mine the ore is exceptionally rich, averaging 10.3 dwt. over an assumed stoping width of 52 inches.

The Village Deep mine shows stoping ore of better grade than the average of the mine for a length of 5000 ft. on the lower level. The orebodies in the Brakpan extend, in some cases, over 700 ft. on the strike and 4000 on the dip, their grade being about the average of the Rand, say $7 per ton.

Imported supplies are expensive: timber $1 per cubic foot, drill-steel $150 per ton. Local coal is cheap, $2.80 per ton. Electric power costs about 1c. per kilowatt-hour.

The daily wage of the white underground employee, whose work is mainly supervisory, averages about $5, while the native, who does all the hard work, gets about 50 cents; the native also receives housing, food, and medical care; adding cost of recruiting and transportation makes the total cost to the company about 75 cents daily.

The Brakpan Mine is one of the most important mines that has been developed in recent years. Its remoteness from profitable mines rendered it a speculative venture; even after $188,000 had been spent on bore-holes and preliminary work, its future was problematical. During 8½ years $5,772,000 was spent in developing the property before milling began. Perhaps no mine that has been opened on the Rand gives more hope for the future of the local mining industry.

The property measures 6000 by 14,000 ft. and is opened by two shafts each 42 ft. x 9 ft. over all. No. 1 shaft reaches the lode at 3098 ft. and No. 2 shaft, distant 4500 ft. on the dip, at 3707 ft. Full descriptions of these shafts were given in the Mining and Scientific Press of April 26 and May 3, 1913.

The No. 2 shaft has four compartments for hoisting; the 3-deck cages take 60 men; the shift of 110 white and 1650 natives is hoisted in 2 hours by a 2100-volt motor of 1450 hp. About 150 tons per hour is handled over a vertical distance of 3850 ft. at a cost of 17c. per ton for 64,000 tons monthly. The main incline connecting shafts No. 1 and No. 2 is 4500 ft. long, 18 ft. wide, dip 7°. Driven from both ends the horizontal error at the meeting-point was 6.5 in., and the vertical error 0.7 in. In a flat orebody, such as that exploited in the Brakpan, minor undulations and faults cause crooked drifts and make development and tramming more costly than in a steep-dipping deposit. The levels are 6 ft. x 7 ft., main haulage ways 14 ft., secondary haulage ways 11 ft. wide. Governmental regulations having forbidden the former practice of first blasting the cut and then the round, after spraying the face with water for 30 minutes, each miner is now given two faces of work, which he blasts on alternate shifts. The cost of drifts in 1914 was $15.87 per foot; haulage-ways cost $25.60 per foot.

Small drills of the hammer type with hollow steel promise in time to replace the larger drills both for stoping and driving. The large drills break 11 tons per shift, the small drills 7 tons; the stoping-width is 70 in. and 57 in., respectively. This poor showing is due to labor conventions that restrict the work of each machine to drilling four holes per shift, each 6 ft. deep. In opening a stope, work is usually started at both the bottom and top of the winze, which, as already noted, is 9 ft. wide. A winch is placed at the top to deal with the upper portion of the stope, and another half-way down to raise and lower the trucks that serve the bottom section by way of the level below. The benches at first conform to diagonals from the winze to the levels, giving the appearance of underhand stoping at the top of the winze and overhand at the bottom, but after reaching a distance of about 100 ft. on either side their lateral extension is checked and they are advanced mainly in the direction of the winze until the stope is opened throughout. Each face is then more or less parallel to the winch track, from which laterals have been thrown off at intervals of 35 ft. for extension as required. 'Backs' vary from 300 to 1200 ft., according to the influence of dip on the distance between levels. Stope-pillars of good size are left where necessary, especially along fault-lines, and these, together with frequently placed 'pig-sty' packs, sufficiently support the roof. As the faces advance right and left the roof of the interior gradually subsides, the weight being taken by the packs. This may or may not call for the shifting of winch-tracks.

The cost of stoping during 1914 was, for large machines 98c. per ton broken, and for small machines $1.20. After allowance for the included ore from development faces and other sources, and for the waste-rock discarded in sorting, the general average was $1.03 per ton milled.

Shoveling and tramming of the ore in the stopes costs 68 cents per ton. Haulage is by an electrically-driven endless rope and costs 10 cents per ton for the 707,575 tons hauled in 1914.

Ore reserves are computed once per annum. The correct estimation of stope-width is of great importance. The flatness of the lode and the use of machine-drills seldom permit of a height less than 48 in., and this is taken for a minimum. As a whole, the stope-width exceeds the average lode-width by 22 inches.

A typical calculation of the value is:

			Dwt. per ton.
	73	From ore reserve	6.7
	17	From development	2.8
	10	From other sources	5.6
	100	to sorting plant	5.98
Deduct	14.5	excluded by sorting	
Deliver	85.5	to mill	6.93
Recovery, with 96% extraction, say,			6.65

Clearly, any variations in the assumptions would correspondingly affect the result. It is necessary, therefore, in making a forecast, either to put forward a definite figure as a measure of existent conditions in the light of probability, or to give limiting figures sufficiently comprehensive to cover the contingencies that may arise.

Concentrates

Readers of the Mining and Scientific Press are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

Cost of making aluminum is approximately 18c. per pound.

The front head of a machine-drill receives the hardest wear and the roughest usage of any part.

Canvas air-pipes have been satisfactorily used for ventilation at the Nourse mine on the Rand.

Aluminum in the United States is produced by the Hall process; in Europe by the Heroult system.

Electric furnaces for smelting iron ore are only of advantage in localities where charcoal and coke are expensive, and where electric power is cheap.

The metal cobalt is considerably harder than either iron or nickel under similar conditions. Its melting point is 1467°C., and tensile strength 34,400 lb. per square inch.

Electricity in metallurgy, apart from refining processes, is used in the manufacture of aluminum, ferro-alloys, pig-iron, and steel; also, to a limited degree, in electric-furnace smelting of copper and zinc ores.

Electric-lighting fixtures about mines must be safe; not only safe under ordinary conditions, but with sufficient insulation and mechanical strength to allow continuity of service under unusual electrical disturbances or mechanical strains.

Gypsum is found in various places in Australia. It occurs as large crystals, and also in minute crystals forming a floury earth known as 'copi.' Both forms are exceedingly pure. It is used as a natural manure and in the manufacture of portland cement.

Cargo-sampling of iron ore is done by taking a sample from the top of the cone under each hatch, and then sampling each exposed face when the cargo is unloaded. By this method the results are high if the last material loaded into the vessel is richer than the average.

Cryolite, a source of aluminum, used also in making soda and glass, is not produced in the United States. The entire supply used in this country is imported from Ivigtut, an Eskimo hamlet on the southern coast of Greenland. The quantity in 1914 was 4612 tons valued at $94,424.

Salt occurs naturally in two distinct ways, as rock-salt in beds or associated with bedded or sedimentary rocks, and in the form of natural brines or bitterns. It is prepared for market by simply mining, crushing, and cleaning the rock-salt, or by evaporation. The latter process may be either natural, as when the sun's heat is utilized, or artificial, when steam or direct heat is applied.

Pneumatic-tools should be kept clean, well lubricated, and limited to the uses for which they are intended, otherwise they will not give the service for which they were designed. The supply of air should be clean, cool, and dry. Some tools require a light machine-oil, and others a heavy grease. It is a good plan to immerse pneumatic-hammers in a bath of kerosene or benzine over night, and then blow them out next day, followed by lubrication.

Acetylene gas is not poisonous, but, like nitrogen, will not support life. One great advantage of acetylene is that it does not make smoke or soot. The spectrum of acetylene discloses the fact that it is the closest approach to sunlight of any of the illuminants. Up to the present no safety-lamp, using acetylene as a source of illumination, has been devised for gaseous mines, but in non-gaseous coal mines it is safe to say that 70% of the miners are now carrying acetylene lights.

Limonite in pisolitic form, an aggregation of concretions, the size of small peas, is found in many localities, but the occurrence of separate spheres of limonite is not so common. They are, however, found in Switzerland, also in the Province of Shansi, China, where they are called iron peas, and the water in which they are boiled is considered a specific for rheumatism. This Chinese superstition is paralleled by many Californians who are paying a dollar for a few ounces of insoluble minerals employed in a somewhat similar manner.

Coorongite, a mineral substance resembling india-rubber, is found near Kingston, in the Coorong district of South Australia. Soft, semi-elastic, with a tarry smell, somewhat reminiscent of Russian leather, it very closely resembles some of the crude African rubbers and would not be taken for a mineral product. An analysis gave C 64.73, C (fixed) 1.00, H 11.63, O 20.38, H_2O 0.47, ash 1.79 = 100.00. Retinite, a brilliant black resin and a pure white paraffin are also found in this same locality. It was thought that these substances originated in oil-bearing strata, but so far no petroleum has been found.

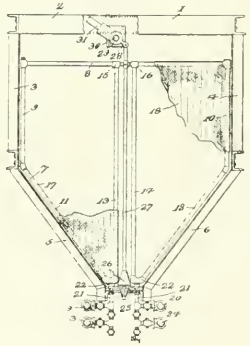
A drag-line excavator may be moved when working on soft material as follows: The drag-lines are operated on four platforms. When a machine is ready to move, and the platform in the rear of it is swung and dropped in place in front of the machine in the direction in which it is desired to move, the drag-line is swung facing the rear. A 20-ft. chain or cable is hooked by means of a clamp on to the platform which has just been dropped in front of the machine. This cable is run under the base of the excavator, and the other end is hooked through the bucket-chain. When the bucket is hoisted, the machine moves ahead easily in the direction desired. With this method, the machine is ready to dig in five minutes.

Recent Patents

Process for the Recovery of Metals from Ores and the Like. Charles S. Vadner, Salt Lake City, Utah. Filed August 7, 1914. Serial No. 855,713.

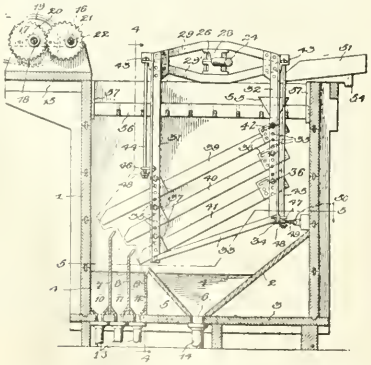
1. A process for extracting metals from mineral matter and the like consisting in treating the mineral matter with smelter fumes and the like containing sulphurous gases in the presence of a solution containing at least one of the common chlorides leaching out the metals from the mineral matter, eliminating excess SO_2 gas by suitable means, passing air through the solution thereby precipitating iron, eliminating and recovering the iron.

Filtering Apparatus. William E. Holderman, Salt Lake City, Utah. Filed June 26, 1913. Serial No. 775,987.



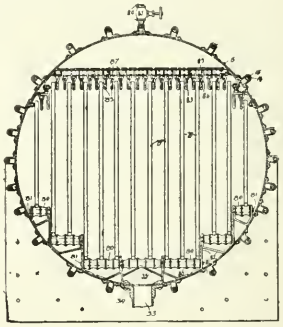
1. In a tank, a filtering partition within said tank comprising an angular framework of perforated piping divided longitudinally into two sections, the top pipe of the framework being common to both sections, cover of filtering fabric stretched across each frame, and means for causing a flow of fluid into and from said partition.

Ore-Concentrator. Fritz Oscar Stromborg, Salt Lake City, Utah. Filed March 26, 1914. Serial No. 827,416.



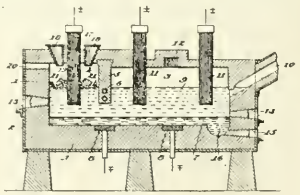
1. The combination of a water tank, a crank shaft revolubly mounted on said tank and extending there across, a substantially rectangular frame supported by said crank shaft, said frame having a pair of oppositely bowed cross bars at its opposite sides, a sectional bearing secured between each pair of cross bars and through which the eccentric portion of said crank shaft passes, hanger bars rigidly secured to and depending from the corners of said frame, bars connecting the lower ends of said hanger bars and thereby forming a rigid frame depending into the tank, screens adjustably mounted on said depending frame, and means for imparting movement to said frame.

Filter. William Poole Lass, Treadwell, Alaska. Filed September 30, 1912. Serial No. 723,064.



1. In a filter, a drum, a plurality of supports on the inner face of the lower portion of the drum, said supports consisting of a set of spaced brackets at each side of the centre of the drum, means connecting the adjacent brackets of the sets together at the top of the brackets, and means connecting the top of each bracket of each set of brackets, with the bottom of the next adjacent bracket, a plurality of filter leaves resting upon the supports, and guides in the upper part of the drum and between which the upper ends of the leaves extend.

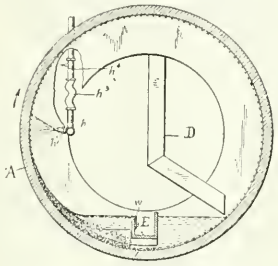
Process of Treating Zinc-Bearing Materials. Woolsey McA. Johnson, Hartford, Connecticut, assignor to The Continuous Zinc Furnace Company, Hartford, Connecticut, a corporation of Connecticut. Filed June 27, 1913. Serial No. 776,185. Renewed December 10, 1914. Serial No. 876,538.



1. A cyclical process of treating a charge of zinc-bearing material low in sulphur and containing silica, which consists in electrically heating the said charge in presence of molten iron, producing thereby metallic zinc and a ferruginous silicate slag, condensing the evolved zinc vapors, recovering iron from the said ferruginuous silicate slag, and utilizing the reduced iron to reduce further quantities of zinc-bearing material.

Concentration of Minerals by Flotation. Archibald R. Livingston, Canon City, Colorado, assignor to The New Jersey

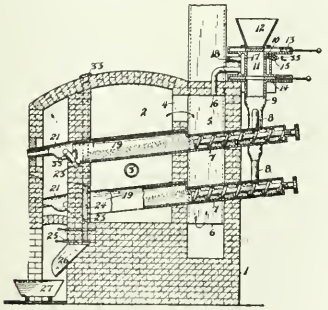
Zinc Company, New York, N. Y., a corporation of New Jersey. Filed December 27, 1913. Serial No. 808,945.



1. The method of separating floatable minerals from material with which they are associated, which consists in feeding the mixture into a body of water, progressively raising it through the surface of the water, meeting the emerging top layer by a downflowing film of water, and floating the top layer thereby into the main body of water at the surface thereof and collecting the material thereby separated separately from that which sinks; substantially as described.

2. The method of separating floatable minerals from material with which they are associated, which consists in feeding the mixture into a body of water, progressively raising it through the surface of the water at an angle greater than its natural angle of repose, lowering the angle of repose of the emerging top layer by a down-flowing film of water and floating the top layer into the main body of the water at the surface thereof and collecting the material thereby separated separately from that which sinks; substantially as described.

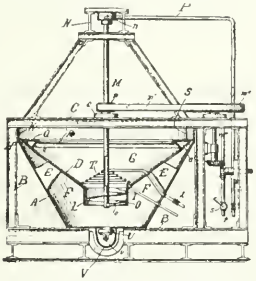
Method of Smelting Zinc and Other Ores. James M. Hyde, Berkeley, California. Filed March 10, 1915. Serial No. 13,377.



1. The process of smelting zinciferous materials which consists in mixing with the zinciferous material a proper amount of reducing agent, charging the same into a retort while preventing the passage of vaporized zinc, through the charging device, vaporizing by external heat the zinc in the retort, and separately removing the vaporized zinc and the solid residues from the retort while continuing the smelting operation, and preventing the passage of gas out of or into the retort through the opening through which the residues are withdrawn.

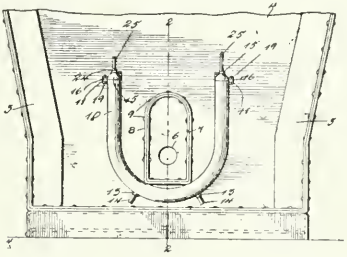
Cyaniding Apparatus. Frederick E. Carman, Jamaica, New York, assignor to Miriam E. Carman, Babylon, New York. Filed October 22, 1912. Serial No. 727,093. Renewed December 22, 1914. Serial No. 878,610.

1. In a cyaniding tank, a receptacle having the form of an inverted frustrum of a cone, a partition having the form of an inverted frustum of a flatter cone and secured within said receptacle to afford outer and inner compartments communicating at their upper peripheral portions and at their lower central portions, and means for creating a current of liquid



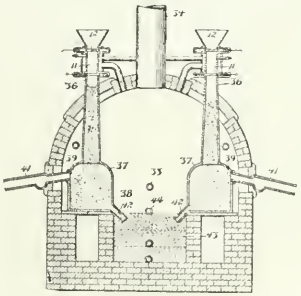
downwardly within said inner compartment and upwardly within said outer compartment; substantially as described.

Water-Jacket. Eulalio Medina, Douglas, Arizona. Filed December 31, 1914. Serial No. 879,942.



1. A water-jacket of the class described comprising a U-shaped hollow body, said body being adapted to be supported adjacent to a tap opening of a blast furnace, said water-jacket having open upper portions and a plurality of detachable caps secured to the upper portions of said water-jacket for closing the open portions, and means connected to said water-jacket and to said caps for maintaining a circulation within said water-jacket whereby the water-jacket will remain in a chilled condition.

Zinc-Smelting Furnace. James M. Hyde, Berkeley, California. Filed March 10, 1915. Serial No. 13,376.



1. A furnace for smelting material containing a volatilizable substance having a heating chamber, a smelting vessel or retort within the heating chamber having an outlet for the removal of volatilizable metal and an outlet for the removal of molten material, a chamber into which said latter outlet discharges, and means whereby said molten material seals against the passage of gas the communication between the latter chamber and the smelting vessel.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

NEW YORK

EXPORTS.— IRON TRADE.— METALS.— PARAFFIN.— ALUMINUM.— COAL.—MUNITION PRODUCTION.—AMALGAMATED COPPER.

Discussion on the War has given place to that on exports. Never was so much interest taken in exports, foreign opportunities, and strange unheard-of places. The significant point about many American businesses at present is change. Firms that formerly scorned foreign trade, with its misunderstandings and long credits, would today be entering bankruptcy if it were not for the unprecedented orders from Europe and South America. Large concerns that had begun to lose faith in big business, on account of reactions and changes in sentiment are as active as in previous prosperous times. Oddly enough, certain miscellaneous insignificant lines of American trade or production are looming up as never before, and making profits they never expected, while a few standard lines of business are dwindling to nothing, being hit instead of benefited by the War.

Aside from the naturally-expected extraordinary increases in the export of food-stuffs, including an enormous expansion in wheat and meat, the most far-reaching and significant gain is in the growing demand for iron and steel goods. A few months ago the iron and steel trade was very slack, with mills and mines at around 50% capacity. Now they are climbing to full capacity. From Coleraine, Minnesota, among the great pits of the Mesabi range, to Woodstock, in the desultory, lonepine areas of Alabama, iron mining is reviving. And at blast-furnaces, steel-mills, and foundries, all over the East and Middle-West, night shifts are at work. Iron and steel manufactures, the exports of which totaled $38,000,000 less for 11 months ending May 31 than in the corresponding period of the previous year, amounted to $26,500,000 for May 1915, compared with under $20,000,000 for May 1914. This shows the trend of events. At the same time it is rather surprising to many people to learn that exports of copper have been consistently for months below normal, in May 1915, $9,800,000, and $11,700,000 in May of last year. The decline is largely due to Germany being cut off. The demand for mineral oils for export is gradually reviving. Exports of zinc in May were worth $2,400,000; this is nearly all gain over normal conditions. It may be remarked that the foreign demand for American zinc, lead, coal, oil, and copper, is more than equaled by the great value exported in such commodities as cars, carriages, autos, trucks, horses, mules, etc., while a host of minor material such as paraffin, wire, boots, cotton-seed oil, aeroplanes, wool, chemicals, tobacco, etc., have sprung into amazing importance. Of interest to miners it may be noted that illuminating the trenches of the European battle-fields partakes of much the same nature as lighting a mine, and the export item of $5,600,000 for paraffin, for five months (December to April), compared to less than half the amount in the same period of the previous year, was increased largely by the use of candles in the trenches. It is presumed that miners' acetylene lamps are favored by the officers, but the ordinary soldier, like the ordinary miner, (sometimes the same man), understands a candle without any explanations.

The export of aluminum has been given a spurt by the unusual conditions of the War, due not only to its substitution for copper which is so costly at present, but also on account of its value where lightness is essential for aeroplanes, soldiers' kits, etc. The Aluminum Co. of America is in a position to supply a large output from its enlarged plants. It has just finished large additions to its plant at Massena, St. Lawrence county, northern New York, where plenty of power for electric smelting of the bauxite ore is obtained from a system of canals across good-sized tributaries of the St. Lawrence river. From a scale of exporting of little more than $1,000,000 per year, aluminum is now leaving the country at several times that rate.

Over in the Naugutuck valley of Connecticut there is great activity. At Bridgeport, Waterbury, New Haven, and Hartford, arms and ammunition factories are 'growing' over night, and more land and buildings are being acquired. Twenty-four hours per day is worked; machinists and mechanics are in demand; towns are doubling in size. Business is so good that the workmen would strike if they had time to plan a decently vindictive strike and to concoct some grievances. Pins, watches, corsets, etc., are temporarily forgotten in the zeal for making war munitions. Concrete walls surround the factories, and earthen bulwarks the fulminate buildings, the former against cranks, the latter against explosions. At powder factories in the little state of Delaware, similar scenes of activity, expansion, and explosives, are seen; the Du Pont family (with the exception of General T. Coleman Du Pont, who sold out recently and went in for life insurance) has had its fortunes greatly enhanced. One authority thinks that Americans who usually spend their summers and money in Europe are procuring excitement in the astounding turns which home business is taking, speculating in and guessing at the unprecedented twists that war and foreign conditions bring. Another authority ventures the assertion that such a change is doubly beneficial for American industries and businessmen, because it gets them out of the rut of 'thinking only of what's under their noses,' that is, the new order tends toward a cosmopolitanism, that even New York knew little of a year ago.

The following partly shows the exports for the five months, December-April, and also shows the trend of European buying in the United States when the magnitude of the War became first appreciated:

	1913-1914.	1914-1915.	Increase.
Horses, mules, harness, etc..	$ 2,393,970	$60,267,925	$57,873,955
Auto-trucks and auto tires..	1,629,246	21,250,708	19,621,462
Machine-tools	5,803,039	15,024,659	9,221,620
Lead	450,887	3,999,150	3,548,263
Zinc and manufactures.....	129,786	9,582,459	9,452,673
Brass and manufactures....	3,286,034	10,076,530	6,790,496
Aluminum and manufactures	537,044	1,706,766	1,169,722
Leather and manufactures..	14,546,256	33,908,078	19,361,822
Chemicals	3,885,151	12,111,946	8,226,795
Men's boots	4,177,100	8,535,601	4,358,501
Explosives	3,474,064	16,685,255	13,211,191
Firearms	1,426,256	4,845,238	3,418,982
Wool manufactures	1,864,143	16,636,288	14,772,145

It will be noticed that many items are larger than those of explosives and firearms, that the increase in explosives is less than the increase in horses, auto-trucks, leather, or woolens, while firearms increased less than nearly anything else. It is true, of course, that many factories had not yet got into swing on explosives and firearms, and that the export record for the remainder of the year will show a decided increase in these items.

Relative to coal conditions, this business was very dull during the early months of the year, due to general industrial depression and to the slump in bunker-coal. A little foreign

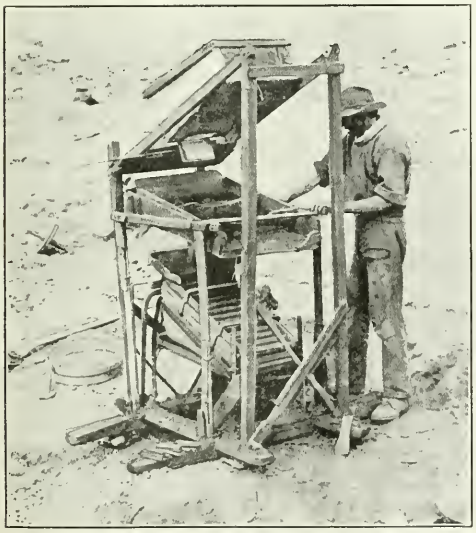
trade has been secured. The May export of coal was $5,800,000, compared with $5,200,000 in May 1914. Another reason for the slow expansion of American coal trade abroad is the undoubted consideration that however clever Americans may be as salesmen in their own prosperous country, and however ingenious in handling low-grade minerals in large quantities at low cost, when it comes to selling a product in Latin countries which those people can possibly get along without, the average American knows little of how to proceed. A little coal is being shipped to South America and the West Indies. Probably of more interest to coal miners is the industrial revival which is now calling for coal throughout the United States, such that, with the iron trade brisking up and factories booming, bituminous coal sales are slowly improving.

It is fitting at this time to say a word about the passing of Amalgamated Copper Co. It was incorporated in 1899 and dissolved in 1915, and was unsuccessful in its main purpose, the domination of the copper industry of the world.

KALGOORLIE, WESTERN AUSTRALIA

Rain and Activity in Prospecting.—Great Boulder Drilling.—Edna May Mine Developments.—Labor Inconsistencies Again.—Beria Consols.—Ivanhoe at Depth.—South Kalgurli.—Gold Yield and Dividends.

The abnormally wet season continues, the rainfall in June being 3 in., making a total of 13.78 in. for the year to date, against an average of 8.9 in. for the previous seven years. The



A WESTERN AUSTRALIAN DRY-BLOWER AT WORK.

highest fall in this period was 12.68 in. (in 1909), and the lowest 5.08 in. (in 1911). Owing to the abundance of water everywhere prospectors have shown great activity in various directions. The greatest drawback to prospecting is the damp surface loam and gravel, making 'dry-blowing' impossible. They have been well backed by Melbourne, Victoria, speculators, and to a lesser extent by those of Adelaide, South Australia, and Perth, Western Australia. So far fully 30 small syndicates and companies have been formed to develop the discoveries. It is too soon to say whether anything persistent has been found. ——At Gibraltar, 16 miles southwest of Coolgardie, the Lloyd George, now held by a Perth syndicate, and the Bulla Bulling, under option to Melbourne people, have produced 16 tons for $960 and 4 tons for $2060, respectively, from small holes. The ground is being opened.——At Grossmount, 6 miles nearer Coolgardie, a large number of areas have been located. Several prospectors have had rich crushings, but only one property looks like becoming a mine. This is held by Nioa and others who have had several lots treated at the Government mill at Coolgardie, 10 miles distant. Returns averaged 3 oz. per ton. The lode in this claim consists of decomposed schist up to 10 ft. wide, but only 3 ft. on the foot-wall is being stoped at a depth of 30 ft., as the transport and crushing absorb $5 per ton, and the cost of treating the residue is $3 per ton, in addition to 75% gold recovered.——At Mungari, 11 miles northeast of Coolgardie, two prospectors, named Penglaise, unearthed 500 oz. in a hole 2 ft. deep. They are apparently afraid to sink deeper, remembering the Londonderry and Wealth of Nations fiasco of the early days. The specimens exhibited in Coolgardie remind one very much of these wonderful finds.—— From Laverton, 211 miles northeast of Kalgoorlie, the Westhead Bros. have treated at Kalgoorlie 35 tons for 375 oz., in addition to 345 oz. recovered by pestle and mortar. They expect to get another 70 oz. from the residue. The bullion is worth $19.80 per ounce. At the time the specimens were found, at a depth of 50 ft., the mine was on offer to Sir Alexander Peacock, Premier of Victoria. He promptly closed the deal, and it is officially reported that there has already been recovered 500 oz. within a week of paying a first deposit of $2400.——New prospects have also been reported from various districts on the Murchison field. Owing to the general use of automobiles, investors and promoters are enabled to examine any new claims soon after they are reported, instead of being handicapped in transport as in the early days.

Although numerous boreholes, covering a distance from north to south of 1200 ft., put in from the Perseverance, have cut ore in Great Boulder ground, Richard Hamilton shows no inclination properly to test the two lodes located by crosscutting and driving on them. Boreholes have now cut the lodes at seven different levels from 900 to 2200 ft. with varying results, in many instances in high-grade ore. Reserves are estimated at 627,900 tons assaying $13.62 per ton. No sinking has been done for four years.

After the cross-cut at 300 ft. in the Edna May had been driven 69 ft., 600,000 gal. of water daily started to flow. This is quite beyond the capacity of the 8-in. Cornish lift, and all work underground is stopped while bailing to assist the pump is being resorted to. The manager, M. Williams, recommends the installation of a steam pump at the 300-ft. level, but steam pumps are not satisfactory. Gold production may be largely reduced for the time being, and possibly the payment of the monthly dividend may have to be suspended. Ore reserves are estimated at 84,000 tons for the three levels opened. Of this total, 54,000 tons, yielding $1,178,690, equivalent to $21.83 per ton, has been treated. This would only leave 30,000 tons in reserve, and yet the directors have ordered additional treatment plant at a cost of $42,000, in order to increase the monthly output to 5000 tons, or 2000 tons more than hitherto. The mine has been a wonderful one so far, but should the water difficulty not be quickly surmounted, the upper levels, if they can be kept drained and stoping can be continued, are likely to be seriously depleted, and the increase in milling plant may be found unnecessary.

Owing to the Murchison Miners' Union prohibiting contract, or bonus, work, the Kyarra mine at Meekatharra has been closed down, and 65 employees have been paid off. In September 1914 the sinking of the main shaft below the 300-ft. level was let on contract, but the Union vetoed this, and the contractors stopped work. After suspending shaft-sinking for seven months, the management arranged in May to pay standard wages with a bonus for extra footage. Under this system the weekly progress was at the rate of 7 to 8 ft., the average cost being $43.20 per foot. The Union, after the first week,

interfered, and prohibited its members from continuing to work on the bonus system. Day labor was then tried, and the weekly advance dropped to 3 ft., while costs rose to $129.60 per foot. The shaft has now been stopped at 328 ft., or only 18 ft. below what it was when sinking was resumed in September. The same Union caused a stoppage on the Yuanmi mine for 68 days, in 1914, by dismissing from the Union 12 men who were sinking the shaft on contract, and then refusing to work with them for being non-unionists. Afterwards they stultified themselves by allowing the work to be done on the bonus system, which they now refuse to allow on the Kyarra in the same district.

The Lancefield, now known as the Beria Consols, has been registered as a limited liability company, with a nominal capital of £50,000 in £1 shares. The directors are F. A. Moss, formerly manager of the Kalgurli; G. Ridgway, late engineer of the Great Boulder Prop.; and A. Porter, managing director of the Kalgoorlie & Boulder Firewood Co. The treatment-plant has been thoroughly overhauled and brought up to date under the supervision of Mr. Ridgway, and it is expected to treat 6000 tons per month with a good extraction and profit. This plant has now been running three weeks and all necessary adjustments have been made to ensure its future proper operation. In the past the mine has produced 572,780 tons for $4,579,800, or, say, $8 per ton. Ore reserves are estimated at 250,000 tons assaying $8.16 per ton. This quantity can be materially increased by the further opening of the bottom levels. The deepest level is at 1000 ft. or the incline, which is only 40°. The ore-shoot in the upper levels is 1200 ft. long, and averages nearly 20 ft. wide.

The Ivanhoe ore reserves are estimated at 998,700 tons averaging $8.94 per ton, or 32 months' supply for the mill. The main shaft is down 3320 ft. A diamond-drill bore from that point penetrated the East lode at a vertical depth of 3457 ft., 189 ft. east of the shaft. The width was 78 in. and the assay-value $7.74 per ton. This development appears to confirm Malcolm Maclaren's theory that the lode and gold-content would again be found below the porphyry bar.

The South Kalgurli's reserves are given as 250,450 tons of an assay-value of $5.94 per ton, equivalent to 26 months' supply for the mill. A short ore-shoot, averaging about $5 per ton, has recently been opened between the 800 and 1000-ft. levels of the Hainault part of the property, but the quantity developed is not sufficient to affect materially the general average value of the mine.

In the *Monthly Journal* of the Chamber of Mines of May 31, the new Federal tariff, which affects the mining industry, is discussed editorially. Higher duties have been imposed on 40 items of importance. The future of mining in the State is discussed by W. A. McLeod, of Bewick, Moreing & Co. Systematic prospecting, aided by the Geological Survey, is necessary.

In Bulletin 18 of the Aust. I. M. E., V. F. Stanley Low discusses the low-working costs of the Corinthian North mine and mill in the Southern Cross district. Total charges are only $2.36 per ton.

The gold yield of the State in April was $2,179,280 and $399,000 in dividends; in May these were $2,201,810 and $54,640, respectively.

MANILA, PHILIPPINE ISLANDS

Benguet Consolidated Mill.—Re-Opening Coal Mines.—Dredging.—Drainage-Adit.—Hydraulicking.—Cement Manufacture.—Iron Ore.—Rock-Asphalt.

The Benguet Consolidated Mining Co. received the last of the machinery necessary to complete its new 10-stamp mill near Baguio, Benguet, on the *Tacoma Maru* which arrived here on July 6. Rain is due any day now, and every effort is being made to transport the material over the Benguet road, which is usually more or less impassable during the rainy season. The new plant is complete except for motors and transformers. Adequate supplies of cyanide and zinc have been secured to last through the rainy season. The company is in a position to operate continuously even though communication with the outside world is cut off by floods.

The resumption of coal mining is promised by the lease of the old Insular Coal Co.'s property at Danao, Cebu, to J. J. Shaw and J. Clyde Nichols. The former made the installation of the hydraulic plant on the Cansuran Mining Co.'s property in Surigao; the latter is a mining engineer who has been in the Philippines for several years. There are four beds of a good grade of sub-bituminous coal at Danao, about one meter thick. A light railroad connects the old mines with the coast at Danao, a distance of about 10 kilometers. This line is being overhauled, a small dock is being built at Danao, and some of the old workings are being re-opened. It is planned to start operations in a small way, the initial daily production to be about 10 tons. The output will be distributed from Cebu, an open port. Inter-island shipping concerns could arrange to take on coal at Cebu. This would make a market for an output larger than that contemplated for the present. As the re-opening of the old pits proceeds, the yield is expected to increase to about 300 tons per day.

There is a movement on foot to re-open the coal beds on the Escaña property at Compostela, several kilometers south of the mines at Danao. The Compostela coal is comparable in quality with the Danao coal, and mining conditions are similar. There is no communication from the Compostela region to the coast at present, other than by foot-trails.

The Malaguit Dredging Co. has taken out papers for a corporation capitalized at ₱1,125,000. Judge Frank B. Ingersoll of Manila is general manager of the company. His brother, residing in Seattle, Washington, is one of the principal shareholders. The company has a new modern dredge, built by the Yuba Construction Co., California, and has been operating successfully for a year or more, on the Malaguit river, Camarines.

The San Mauricio Mining Co. has let a contract for the driving of an adit to unwater the old workings near Mambulao, Camarines. The proposed opening will start from a point north of the town of Mambulao, just above sea-level, and will drain the mine to a depth of about 250 meters below the collar of the main shaft. The length of the adit as planned will be nearly 2000 meters. The formations to be penetrated are schist and gneiss. Inasmuch as the adit will be directed across the strike of the principal known veins, and will cut these considerably below the deepest former workings, it is expected to yield valuable information. The contract has been awarded to A. C. Cavender; work will begin immediately. A small air-compressor is being installed, and machine-drills will be used in the excavation.

Some Manila mining men have secured a lease on placer ground on Cabu river, in Nueva Ecija province. An attempt is being made to sluice a part of the area. The gravel is washed down by means of a small pressure-pump, pipe-line, and 1-in. nozzle, into a sump, from which it is elevated to the head of the sluices. The presence of gold on Cabu river has been known for many years, but this is the first attempt at mining. The gold is well rounded, and small nuggets are not uncommon. The ground has not been thoroughly tested, and it is impossible to give the value. The present work is really in the nature of exploration.

The Mambulao Placer Co. has received the first shipment of material for its new dredge to be built at the head of Mambulao bay, Camarines. The New York Engineering Co. has the contract for this boat, which will be similar in design to the dredge built by the same firm for the Gumaos Placer Co., three years ago. The new one will embody certain improvements, however, designed to facilitate the handling of large volumes of barren clay overburden.

The Rizal Cement Co., Binangonan, Rizal, began burning

cement on July 1. This plant was purchased complete from the Krupp works at Magdeburg. It has a single rotary-kiln, 34 meters long and 2 meters diameter, and will produce about 500 bbl. of cement daily. Power is generated by Locomobile engines. Grinding both the raw ingredients and clinker is done by ball and tube-mills. The installation includes an aerial tramway 7½ kilometers long, from quarry to mill. This line, as well as the mill machinery, was purchased in Germany, and the installation has been entirely in the hands of German engineers. The raw materials at Binangonan are a pure, crystalline limestone and a fragmental andesite-tuff.

A recent *Press Bulletin* issued by the Bureau of Science, Manila, summarizes the results of the official survey of the Surigao iron-ore deposit. The estimates specify a total quantity of 500,000,000 metric tons of ore distributed over an area of approximately 100 square kilometers. Over 400,000,000 tons are so situated as to afford possibilities for mining. About 275,000,000 tons are fairly accessible from the coast, and 130,000,000 tons lie within a comparatively short radius of Dahikan bay, which affords natural harbor facilities and at which a base of operations might be established. The ore occurs as a mantle of limonitic c'ay overlying serpentine. It is a residual decomposition product, and is thus similar in character to the Mayari iron ores in Cuba. The Surigao ore, after sintering, would contain from 53 to 54% of metallic iron, allowing for 3.5% of re-absorbed moisture. It is free from both phosphorus and sulphur. Like the Mayari ore, it contains a little chromium, but nickel, which is present in proportion of about 1% in the Cuban ore, has not been detected in the Surigao ore. The country in which the ore occurs is semi-mountainous, and the deposit is separated into distinct areas by numerous deep cañons. While a great deal of the ore is adjacent to the coast, yet mining operations, no matter where they are undertaken, would have to include the transportation of the bulk of the ore from the tops of hills varying in elevation from 200 to 400 meters, down to sea-level. Water-power is available, but in undetermined quantity.

A recent investigation by the division of mines, Bureau of Science, on the island of Leyte, revealed the presence of a considerable deposit of rock-asphalt, which, so far as can be judged from the results of chemical examination, ought to be suitable for paving purposes. Good pavements are very expensive in the Philippines, and it is probable that the rock-asphalt will come into extensive use if it proves to be satisfactory. The presence of the mineral in Leyte had not hitherto been known, although numerous small deposits of solid bitumens had been found. It develops that many of these outcrops of pure, solid bitumens are of no commercial importance because of the limited quantities which they represent. Certain well-defined veins of a bitumen, which is probably to be classed as grahamite, are however, worthy of exploration. A bitumen-cemented breccia of clay-tuff has been found in a deposit which appears to be extensive enough to be important. This material contains about 25% of bitumen, and it is possible to recover about 70% of the total bitumen in the shape of heavy oils, kerosene, and (a little) gasoline, by fractional distillation. Petroleum is associated with the solid bitumens in Leyte and appears at the surface at three different places. The petroleum has a paraffin base, and yields a high proportion of burning oils. The rocks in the Leyte asphalt and petroleum region are Miocene and younger in age, and consist principally of shale, clay-tuff, and tuff-sandstone. The structure of the field is complex, and the sedimentary formations have been intruded at numerous places by small domes and sheets of andesite. In its general features, the Leyte field is closely related to the better-known petroleum regions in Tayabas and in Cebu. None of the fields have been exploited commercially.

The three boats of the Philippine Dredges, Ltd., continue to make good returns.

LONDON

Tough-Oakes Finances.

The company that was organized in London to operate the Tough-Oakes gold mine at Kirkland Lake, Ontario, has come to an inglorious end. A year and a half ago, a great splash was made on the Stock Exchange by the flotation of the Kirkland Lake Proprietary, a company promoted by H. G. Latilla to acquire interests in the Tough-Oakes and other mines in the district. Shortly after an English company was formed, called the Tough-Oakes Gold Mines, Limited, to acquire through the Kirkland Lake Proprietary 426,388 fully paid $5 shares in the Canadian company of the same name, together with options on 171,110 further shares. The consideration for the shares and options was £127,152 cash, and £246,250 in fully paid shares of the English company. The issue of shares in the English company on the London market provided the company with £200,000 in cash. Of the money thus received, £44,996 was paid to the Kirkland Lake Proprietary for 66,781 shares in the Canadian Tough-Oakes company, and also £30,253 for Kirkland Lake Proprietary shares. The latter shares were apparently bought from the Union and Rhodesian Trust, another of Mr. Latilla's companies, which acted as secretaries to the Kirkland Lake Proprietary and the English Tough-Oakes. After these payments a balance of £124,749 remained, of which presumably a large portion would be required for completing the purchase of the shares in the Canadian Tough-Oakes company. Most of the money, namely £112,831, was however advanced to directors and companies of the Latilla group, the security when such existed consisting of shares in these companies. What the actual value of these securities would have been had the War not happened is not clear; but no doubt the shares could have been negotiated in one way or another on the Stock Exchange and the loans liquidated. The War, however, upset all calculations. The money could not be recovered, and the shares became unsaleable. The English Tough-Oakes found itself in the awkward position of not being able to complete its contract to buy the Canadian Tough-Oakes shares. An action has been commenced in the Courts to enforce the contract, and a second action was brought petitioning for a compulsory winding-up of the English Tough-Oakes company. The hearing of the petition is postponed until the first action is completed. How the contract is to be enforced is not clear. It is a pity that so good a little mine, with which are associated as engineers men of repute, should become involved even distantly in this unpleasant financial tangle.

COBALT, ONTARIO

Coniagas, O'Brien, Kerr Lake.

In spite of the low price of silver there is a brisk demand for the purchase of silver prospects in the Cobalt district.

The Coniagas company is constructing an addition to its concentrating plant to recover silver lost in the slime. Twenty-four canvas-tables, laid on cement floors, having a total area of 4000 sq. ft., are to supplement the concentrators. It is expected that 3 to 6 tons of rich silver concentrates will be produced from the 70 to 80 tons of slime made from crushing 180 tons of ore. The canvas concentrate will be treated by cyanide in a small plant of 6-ton capacity.

The O'Brien Mining Co. has commenced work at its property in the Gillies Limit, and known as the A-1. It is situated on the ridge running south from the McKinley-Darragh, and adjoins the lot on which the Temiskaming and the Hudson Bay are working. A head-frame is almost completed, and a shaft will be sunk 200 ft. The ores contain silver and galena.

It is rumored that the Kerr Lake company is negotiating for purchase of control of the old Drummond mine, which at one time was the premier producer of the Kerr Lake section.

The Dome July output was 28,300 tons of $4.67 ore.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

The Alaskan Engineering Commission, which is to build the Government railroad from Seward 471 miles to Fairbanks, has received a permit from the Forest Service to cut 85,000,000 ft. of timber in the Chugach national forest for use in constructing the new line. The permit was issued by the District Forester at Portland, Oregon, who has direct supervision of the Alaskan forests, and is in conformity with the Act of March 4, last, which authorized the Secretary of Agriculture to permit the Alaskan Engineering Commission and the Navy Department to take from the national forests free of charge earth, stone, and timber for use in government works. The timber will be cut in designated areas along the right-of-way of the proposed railroad, which runs through the Chugach forest for several miles. Experiments and tests of Alaskan spruce and hemlock are being made at the Forest Service laboratory at Seattle, and so far have substantiated the opinion of foresters that Alaskan timber is sufficiently strong for practically all structural purposes. While these facts are going on Forest Service employees in Alaska are marking the timber to be cut along the proposed railroad, the cutting to be done so that only mature trees are taken, the young trees being left uninjured, and the condition of the forest improved. This cut of 85,000,000 ft. will be the largest amount of timber ever felled on the Alaskan forests at one time. At the average rate per 1000 board feet obtained for timber sold from the Chugach forest during the fiscal year 1914, it is worth approximately $145,000 on the stump. It will be nearly twice as much as the total quantity of national forest timber now cut and used annually for local purposes throughout Alaska, but only a little more than one-tenth of the estimated annual growth of the Alaskan forests. The two national forests of Alaska contain about 78,000,000,000 ft. of merchantable timber and it is estimated by the Forest Service that more than 800,000,000 ft. could be cut every year forever without lessening the forests' productivity.

The area of the Chugach national forest, which is to be crossed by the railroad that the Government is building from Seward to Fairbanks, is reduced nearly one-half by a proclamation, signed by President Wilson, returning approximately 5,802,000 acres to the public domain. This action follows classification of the land by the Forest Service showing that the areas involved are not of high enough timber-value to warrant Government protection, and means the largest elimination of national forest land ever made by a single presidential proclamation.

Juneau

The Alaska Mexican company reports that in June the 120-stamp mill crushed 14,254 tons of ore for gold worth $15,231. The cyanide-plant treated 365 tons of concentrate, yielding $10,805. Out of the total return of $26,036 the profit was $3527. Owing to the accident to the Central hoist the mill only worked 19 days 16 hours.

At the Alaska United 270 stamps crushed 43,209 tons for $39,092. Nine hundred and forty-one tons of concentrate yielded $36,324. The output was $75,406, and profit $9427.

ARIZONA

Cochise County

Churn-drilling costs at the Sacramento hill is the subject of a paper by Arthur Notman of Bisbee in Bulletin 104 of the A. I. M. E. This hill is a mass of granite-porphyry intruded along a fault between Paleozoic sediments and pre-Cambrian schists. The outcrop of the hill is elliptical and approximately 3000 ft. long and 1400 ft. wide. The Sacramento shaft, the main hoisting-shaft of the Copper Queen property, is situated at the east end of the hill. The Hollbrook shaft is at the west end. Prospecting the hill started from these points at 400 ft. This was continued to February 1913, when a good deal of 3.53% ore had been developed by 19,604 ft. of workings. Churn-drilling was then decided upon from the surface. No. 1 steam-driven churn-drill put down 28,770 ft. in 22 months at a cost of $1.402 per foot. The footage per 8-hr. shift was 16.7. No. 2 and 3 Armstrong electrically-driven churn-drills put down 37,064 ft. (average hole 427 ft.), at $2.385 per foot. No. 1 steam drill on Sacramento hill drilled 16,617 ft. at $1.115 per foot. No. 2 drill was in bad ground.

Mohave County

Good ore has been opened at 400 ft. in the Black Eagle workings of the Tom Reed company. Some time ago 40 ft. of low-grade ore was cut at 200 ft., and the superintendent, W. J. Dower, of these claims predicted that good ore would be found at 400 ft. The shoot is the southeast extension of the Tom Reed vein system. The ore is worth $20 per ton. The width has not been determined yet. A new shoot was found last week at 500 ft. in the Ollo Oatman portion of the Tom Reed.

Ten days' pumping has unwatered the Orion mine. Men are now cleaning out the workings. Los Angeles people control the property. It has produced a good deal of gold, but was closed several years ago.

The Tom Reed company has passed its monthly dividend and bought control of the Crown City property, north of the Tom Reed, for $200,000. Development has been under way for several years by the previous owners.

Little is heard of the Golconda mine, but it is sending 100 tons of 40% zinc ore to Bartlesville, Oklahoma, every day. Net returns are said to be 9c. per pound of zinc.

Pinal County

At 900 ft. in the Magma mine the vein was recently cut, the first 7 ft. assaying 17% copper, 13 oz. silver, and $3 gold per ton, and the next 5 ft., 3% copper, the other metals not being given. The face of the cross-cut is in mineralized formation containing some chalcopyrite.

CALIFORNIA

Amador County

The preliminary estimate of the Plymouth Consolidated's July run is as follows: ore treated, 11,000 tons; gold recovered, $55,000; operating expenses, $29,081; development charge $3919; net surplus, $22,000.

Calaveras County

It is proposed to increase the Calaveras mill's capacity to between 500 and 600 tons per day. Copper ore and concentrate continue to be dispatched regularly. Experimenting is giving good results.

Eldorado County

A deed has been recorded at Placerville showing that J. A. Britton, of San Francisco, has sold to L. C. Burpree, of Oaklank, several placer claims on the middle fork of the American river in this county for $30,000.

Nevada County

Grass Valley district mines are employing more men than ever before. The total is 1000, of whom 400 are employed by the North Star company (not including 250 at its Nevada City

property), 330 by the Empire, 110 by the Brunswick, 43 by the Golden Center, 30 by the Union Hill, and many others at the Black Bear, Osceola, Signal, Cassidy, and Kenosha mines. Foundries and other industries employ about 250 more. The city has now a population of approximately 6000 people. Orchards and farming help to add to the importance of the centre.

The Kenosha mine, four miles below Grass Valley, which has been closed for four years, is being unwatered. It will then be examined. G. F. Drake and San Francisco people have a bond option on the property.

PLUMAS COUNTY

A 100-ton flotation plant is to be installed at the Walker mine, 25 miles north of Portola, according to J. F. Cowan of Salt Lake City. F. E. Steffy will supervise its erection. Over 30 men are employed at the mine, in which a wide vein has been opened, some of it assaying 6% copper. An aerial tram 1.5 miles long will carry ore to the plant.

SAN BENITO COUNTY

The New Idria Quicksilver Co. is attracting attention on the Boston Stock Exchange, on account of large profits from the increase in price of mercury. The capital is $500,000, $5 par, now $12. In 1914 the dividend was 14c. per share. A profit of about $350,000 is expected this year, and $1.50 per share may be distributed.

SHASTA COUNTY

(Special Correspondence.)—The Mammoth Copper Co. is building a road to its Friday-Lowden mine to facilitate transport of supplies and ore. Surveys are being made for a tramway from the Stowell mine to connect with the ore-conveying system to the Kennett smelter. The tramway will be approximately two miles long. Developments are proceeding vigorously at the Stowell and Spread Eagle mines, with 35 men employed. Preparations are being made for extensive work at the recently-acquired Golinsky group. A large tonnage of ore is available for immediate extraction and early shipments to the smelter are planned.

The general manager, Frank M. Leland, of the Balaklala Copper Co. is to arrive at Coram about August 20 to take charge of operations. The trestle at the railroad end of the tramway has been re-built and other improvements made to the line. It is understood that ore shipments to custom smelters will be resumed pending the result of tests with the improved Cottrell process at the Coram plant. Re-building of the smelter stack will commence in the near future.

Developments are proceeding vigorously at the Dry Slide gold mine, near Keswick. Steady shipments to the Martinez smelter of the Mountain Copper Co. will commence soon. Fred McCarthy is manager.

The Sugar Loaf mine, near Copley, has been taken under option by L. G. Cliewe. An examination of the ore reserves is proceeding. The mine contains gold-bearing quartz, and has been worked intermittently. It is owned by F. M. Archer of Montgomery Creek, California, and Robert A. Martin, Portland, Ore. The purchase price is $10,000.

Frank S. Green, of Ono, has started preliminary work on the Bell Cow and Lost Calf claims, near Harrison Gulch.

The Green Horn Copper Co. is completing improvements at the mine which will enable the management to ship 15 to 20 tons of ore daily to the Kennett smelter. San Francisco people are largely interested.

The Gambrinus Mining Co. is driving a cross-cut from the lower level in hope of intersecting the main orebody. The mine is at Stella. H. F. Rogers is superintendent.

Redding, August 16.

At Heroult, the Noble Electric Steel Co. has two furnaces producing ferro-manganese, and one making ferro-chrome. The output is to be increased.

SIERRA COUNTY

Another rich pocket has been opened in the Tightner mine.

COLORADO

CHAFFEE COUNTY

In Bulletin 104 of the A. I. M. E. the Salida smelter of the Ohio & Colorado Smelting & Refining Co. is described by F. D. Weeks. The plant is at an altitude of 7000 ft., 215 miles southwest of Denver, on the D. & R. G. line. The Crested Butte coal and coke, and lime deposits at Monarch and Garfield are nearby. The plant contains six lead blast-furnaces, two copper-matting furnaces (not used), three Godfrey and one Wedge furnace, and four Dwight-Lloyd sintering-machines. The capacity of the whole is 500 tons per day, the chief lead supply coming from the Coeur d'Alene in Idaho. Ores with iron in excess are obtained from Leadville, and the silica supply is helped out by clinkered zinc-residue from plants of an allied company operating in Oklahoma. A longer abstract of this article, dealing with peculiar original construction at the plant, appears on page 282 of this issue.

LAKE COUNTY (LEADVILLE)

At the Penrose shaft of the Down Town scheme, the pumps will soon be working at full capacity again. There is still 405 ft. to be unwatered to the 875-ft. level.——The zinc-oxide plant is working full time. Most of the carbonate ore treated comes from the Robert E. Lee mine on Fryer hill.——Results at the St. Louis continue to be excellent. Some zinc ore has been opened, in addition to the rich gold shoot.——The Waterloo, on Carbonate hill, is shipping 150 tons of manganese daily. ——Lessees at the Forest City No. 2, at Big Evans, are developing a promising vein.——The Bwlchcogh mine, Twin Lakes district, is to send ore to the A. S. & R. smelter. The output will be 50 tons per day.——The Gordon-Tiger mill is being rapidly erected. As soon as the Robert Emmett owners can arrange for the sale of their zinc ore the output will be largely increased. Regular lots of 25-oz. silver and 21% lead ore is shipped.

MINERAL COUNTY

(Special Correspondence.)—There is very little doing at Creede, and the present price of silver is not conducive to new work.

The Creede United Mines Co. is operating the Humphreys mill on ore from the Happy Thought and adjacent properties, and is shipping about 325 tons of lead concentrate per month, also a small amount of zinc concentrate.——The Last Chance-Del Monte is shipping about 300 tons per month.——The Commodore is being worked in a small way by lessees who are shipping about 250 tons per month.——The Equity company is sinking from its adit. To continue development it expects to put in a small compressor and hoist driven by an oil-engine in the near future. Tests have shown that the ore is amenable to cyanidation. If the development continues favorable a mill will be erected.——The Denver & Rio Grande company has a corps of surveyors working on the proposed broad-gauge line to Durango. Everybody seems to think that the company is really going to build it in the near future. This line will start from the Creede branch at South Fork, and pass through Pagosa Springs. If it is built it will cause a considerable boom in the southwestern part of Colorado and in northwestern New Mexico. This line has been talked of for 15 or 20 years, and it is difficult to believe that it is really going to be built. If it is built, and if the Southern Pacific builds its proposed line from Lordsburg to its coalfields near Durango it will give a new and shorter route to Los Angeles.

Creede, August 14.

SAN JUAN COUNTY

Flotation processes are attracting considerable attention in this county, especially around Silverton. Good results are obtained at the King and Mears-Wilfley mills. A plant is in course of erection at the Hamlet mill, and arrangements are being made to add a plant to the Iowa-Tiger. At the Silver Lake mill the American Ore Flotation Co. is getting excellent returns.

IDAHO

Shoshone County (Coeur d'Alene)

Final figures of the output of the mines of this region in 1914 are now available, as filed with the county assessor. They are as follows:

	Tons.	Value.	Profit.
Caledonia	22,336	$ 560,958	$ 322,857
Gold Hunter	10,543	421,318	45,926*
Sierra Nevada	77,270	566,825	159,240
Bunker Hill & Sullivan	440,819	3,374,388	802,559
Hecla	123,857	925,869	196,137
Federal (Mullan)	202,400	1,257,192	99,122
Federal (Wardner)	219,200	942,108	72,943
Green Hill-Cleveland	190,965	2,324,961	1,046,757
Snowstorm	60,958	371,125	22,394*
Tamarack-Custer	20,685	957,359	182,256
Interstate-Callahan	88,664	828,961	187,063
Hercules	60,559	4,147,610	1,868,762
Success	82,664	232,520	23,946*
Ontario	88,857	712,667	239,175
Stewart	189,615	2,140,363	854,433
Yankee Boy (lease)	358	38,646	4,557
D. Blake (Yankee Boy royalty)	.....	.....	6,891
Total	1,899,750	$19,802,393	$6,042,752

*Loss.

Mining, etc., totaled $6,653,269; freight, $6,399,079; and repairs and improvements, $1,133,037.

The president of the Snowstorm Mining Co., Leo Greenough, recommends that the surplus of $172,762 be spent in purchasing two properties and developing new producing mines with the present equipment. In September last the Snowstorm orebody cut out and work was stopped. Fire last week destroyed the power-plant, compressor, boiler-house, etc., at the Rex (Sixteen-to-One) mine. Men from the Interstate-Callahan helped to fight the flames. The plant will be replaced, according to the manager, M. J. Sweeny.

New York, San Francisco, and Spokane people have acquired the Rex mine in the Nine-mile district, near the Tamarack & Custer, for $200,000. It has been shut down for about five years. The property is equipped with mining and milling plant. The lower workings are full of water, and three weeks will be required to drain them. Charles Sweeney is general manager.

At the National copper mine the electric-haulage system, from the mine to the mill storage-bins, is being installed. It is expected that the 500-ton mill will start early in September. The main shaft is 1200 ft. below the main adit.

MICHIGAN

Houghton County (The Copper Country)

The Calumet & Hecla is now mining up to 12,000 tons of ore daily.——The Winona company is experimenting with leaching.——The report of the Wolverine company shows the following in its financial year: ore stamped, 397,614 tons; mineral produced, 9,734,850 lb.; copper in mineral (74.48%), 7,250,866 lb.; revenue (12.81c. per pound), $929,193; total cost (8.43c. per pound), $610,991; profit, $318,202; dividends, $360,000; and surplus, $787,311. Ground opened at No. 35, 36, 37, and 38 levels of No. 4 shaft was generally satisfactory. Work at No. 3 shaft was also good. About 44.6% of the ore hoisted was broken by 'Jackhamers.'

MISSOURI

Jasper County

Prices of zinc-blende during the week ended July 7 varied between $75 and $100 per ton for 60% product. The output of the region was as follows: blende, 6404; calamine, 218; and lead, 1330 tons, averaging $86.64, $50, and $52.37 per ton, respectively. The total value was $635,380. Up to the above date, the Missouri-Kansas-Oklahoma region had produced $14,000,000, an increase of over $1,000,000 for this period of 1914.

The Granby company's drilling campaign at Chitwood has resulted in four holes cutting ore in disseminated formation at 130 to 180 ft., assaying about 5% blende and lead. This ore will be taken to the B. H. mill, a distance of 800 ft., for treatment.

MONTANA

Cascade County

After 2 years 8 months and 4 days' work, the Montana Power Co.'s dam at the Big Falls of the Missouri river was completed last week. Water is flowing over it. The structure is 1340 ft. long and contains 216,000 cu. yd. of concrete.

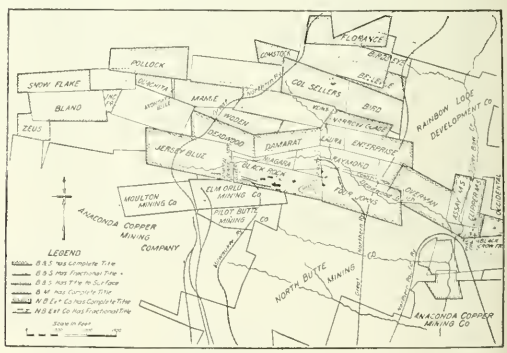
Fergus County

During July the North Moccasin mine of the Barnes-King Development Co. produced 3610 tons of ore yielding $28,000. An oil-fired revolving-roaster is being installed with other plant, costing $11,000. The Piegan-Gloster mine treated 1759 tons of $9.91 ore in July, with 84% recovery. High-grade concentrate was also produced. An electric hoist is working at the Gloster shaft, which is to be unwatered. The Norman adit is in 770 ft., in quartz worth $5 per ton. The dispute between the company and the Kendall has not been settled.

Silverbow County

Two men were killed at 2800 ft. in the Tramway mine by a premature blast last week. The cause is unknown.——The North Butte company is to increase its output to 2,500,000 lb. copper per month. The first half of 1915 yielded 7,800,000 lb., giving $425,000 net.

The Black Rock shaft of the Butte & Superior is down 1900 ft. in ore averaging 18.2% zinc.



BUTTE & SUPERIOR PROPERTY.

The second Montana state first-aid meet was held at Billings on July 23 and 24, under the auspices of the Montana Coal Operators Association, United Mine Workers of America District No. 27, Anaconda Copper Mining Co., U. S. Bureau of Mines, and the American Mine Safety Association. Prizes were awarded to the teams making the highest general average in all events. The winners were as follows, the contests being one-man, two-men, three-men, and full team event: First, silver contest medals and a silver loving-cup, team No. 5 of the Leonard mine, Butte; second, bronze contest medals and $75 cash, team No. 9 of West Colusa mine, Butte; third, $50 cash, team No. 10 of Washoe reduction works, Anaconda (this team was tied for third place by team No. 6 of Klein, but in working off the tie, team No. 10 won third place); fourth, $30 cash, team No. 6 of Klein; and, fifth, $20 cash, team No. 8 of Tracey. The special prize of a silver loving-cup

presented by the Montana Coal Operators Association, and held for the past year by the Red Lodge team, was won this year by team No. 10 of Anaconda for making the highest average in the team problems.

A mine had been built of 2 by 4 in. lumber and tar-paper, in which it was proposed to have an explosion and rescue of supposed victims. The explosion took place all right according to schedule, but on account of the heat of the sun, the flash of the black powder used in the explosion set fire to the heated tar-paper, and before the rescue crew could enter the tunnel the entire structure was in flames. The men who were to have acted as victims were obliged to escape through the sides of the mine before the rescue-crew arrived. So from the view-point of the rescue-crew, the demonstration was more or less of a failure, but from that of the audience it was a spectacular success.

NEVADA

Esmeralda County

The July return of the Jumbo Extension is estimated at 2900 tons of ore worth $101,500. Sampling, freight, and treatment cost $28,000; and mining, development, and general, $13,500; leaving $60,000 profit. The present output is at the same rate. Good results continue from exploration of the shale and contact veins. Above 945 ft. they are one, but split just below, at a fold fault. Rich ore is being opened at all points.

Humboldt County

The Darby mill at Seven Troughs has been overhauled, and is treating ore from the Delaware mine, which is developing well. The plant consists of 10 stamps and cyanide-plant of 100-ton capacity.

Fire on August 16 destroyed a large part of the town of upper Rochester.

Nye County

Tonopah mines last week produced 10,320 tons of ore valued at $211,720. Some July returns were as follows:

Mine.	Tons.	Yield.	Profit.
Belmont	14,020	$171,556	$72,459
Extension	7,754	.....	*40,340
Jim Butler	....	.....	30,751
Tonopah	12,390	160,935	77,165

*June.

At 1260 ft. in the Extension the vein has been opened for 450 ft. Stopes average 12 ft. in width.——At the Jim Butler a great deal of development is in progress.——In the West End a cross-cut has opened ore 200 ft. below any previous shoot found.——Lessees are doing well in several mines.

Storey County

The 2700-ft. level in the east branch of the Comstock has been opened for exploration, and the main Comstock lode in the north end workings has also been rendered available to within a few feet of the 2700-ft. level, the principal necessary air connections for the main Comstock in that region having been made individually by the Ophir, Mexican, Union, and Sierra Nevada companies. By means of the drainage system installed, the main Comstock lode above and below the 2500-ft. level in the north-end mines has been made accessible for exploration for the first time since 1884. Water being pumped from below 2700 ft. is less than anticipated. Drainage to 2900 ft. can be continued, and ore at that depth developed. This work is done under the auspices of the Comstock Pumping Association.

NEW MEXICO

Santa Fe County

The Santa Fe Gold & Copper Co. is attracting attention on the Boston Stock Exchange. The company is controlled by the Lewisohn's. It has 3400 acres of mineral area, and 46,000 acres of coal and other land 20 miles from the Atchison railway. Late in 1913 a blast-furnace started work. Production was suspended on account of the War, but resumed in May 1915. July profits were $26,000. Additional funds may be required for the erection of another 125-ton furnace. The total capacity would be 90,000 tons of ore per year, yielding 7,500,000 lb. copper. To treat the low-grade ore a flotation plant is being considered. Motor-trucks are used for carrying metals and supplies.

Socorro County

The Socorro Mining & Milling Co. has purchased, at a sale by order of the Court, the Mogollon Gold & Copper Co.'s property for $100,000. The estimated output is $1,250,000, of which only $22,500 was paid in dividends to 1906. The claims are in the Cooney district of the Mogollon mountains, 85 miles northeast of Silver City. Work is to be resumed at an early date.

OKLAHOMA

Okmulgee County

A smelter is being erected at the new town of Kusa, about five miles east of Henryetta, by G. E. Nicholson and others. There is plenty of natural gas available at low prices. Joplin zinc concentrate will find a good market at the new plant.

Ottawa County

The Empire District Electric Co., operating in the Joplin, Missouri district, will extend its transmission-lines 24 miles into the Miami area.

TEXAS

Culberson County

(Special Correspondence.)—Extensive development of the zinc mines of El Paso and Culberson counties, in western Texas, is promised as a result of a recent visit to this part by a party of Missouri zinc-mining men. It has been known for several years that large deposits of zinc ore existed in this part of the state. Considerable development has been carried on from time to time on one of the larger mines in El Paso county. The mining men who are now arranging to take hold of the properties with the view of placing them on a large producing basis are J. D. Cameron, Charles Hart, and A. D. Corbin, all of Joplin, Missouri. Mr. Hart took samples from the different properties.

Advise has been received here of the discovery of rich bismuth ore in an old mine on the Texas-New Mexico line, north of Van Horn. The prospector who located it is Joseph Taylor. A preliminary shipment has just been made to New York, and it is stated that plans for development of the mine will depend largely on the returns that are received from this shipment.

An unusual amount of mining activity is reported to be now in progress in the Allamore district, situated northeast of Van Horn. Four separate camps have been established there and many gold claims are being prospected. J. I. Johnson reports that he already has a considerable quantity of high-grade ore on the dump. The outfitting and supply point for the district is Toyah, Texas, on the Texas & Pacific railroad.

T. B. Everheart, who recently leased the Enterprise mine, situated near Van Horn, from T. R. Owen, has begun developing the property on a large scale. He is making regular shipments of copper ore to the smelter at El Paso.

Recent shipments of copper ore from the Pecos mine, near here, to the smelter at El Paso, brought returns of $14 to $28 net per ton.

Van Horn, August 10.

UTAH

Salt Lake County

The Utah-Apex Mining Co. will pay 12½c. per share, equal to $63,000, on October 1. This is the initial quarterly dividend. The cash on hand amounts to $200,000. The output is at the rate of over 30,000,000 lb. of lead per year. Costs will be reduced by the flotation plant being erected.

Summit County

Shipments from Park City during July were as follows: Silver King Coalition, 4440; Daly-Judge, 2268; Silver King Consolidated, 1725; Daly West, 983; Ontario, 983; E. J. Beggs, 47; Big Four Exploration, 104; G. A. Keeps, 36; and Daly company, 70 tons, a total of 10,051 tons.

The Snake Creek tunnel is now in granite, and the daily progress is about 16 ft. No timber is necessary. The flow of water is 7650 gal. per minute. A power-plant is to be erected to be driven by this water.

WASHINGTON

Spokane County

It is estimated by Charles T. Underwood, secretary of the Spokane Stock Exchange, that sales by the 20 brokers who are members aggregated not less than $1,500,000 in July. It is thought that this record will be beaten in August, as the activity among investors has increased greatly in the last 10 days. Trading is principally in Coeur d'Alene companies.

Stevens County

The Silver Trail Mining Co. has been organized by Spokane people to develop the old Clugstone mine, eight miles east of Evans in the Colville district. A. O. Smith is in charge. A lower adit is in 700 ft., partly on a vein.

CANADA

British Columbia

The Nelson district is unusually busy, in spite of a lack of money for new development. Spokane people are being interested in the Alpine property, 12 miles up the Kootenai river from Nelson. According to A. Larson, about $12,000 has been spent in preliminary work on the low-grade free-milling gold ore. Three adits have been driven. About $500,000 is required to bring the mine to the producing stage.

Sixteen miles from Anyox are the four claims of S. J. Eubank and D. F. Jones. A wide lode runs through them, cut at intervals by dikes. The ore assays from 0.01% copper and 40c. gold to 2.7% copper and $1.60 gold per ton. A drill has put down a hole 85 ft., of which 64 ft. averaged 4.2% copper and good value in gold. A fair equipment has been installed. Under certain conditions the owners are willing to sell a quarter interest in the property.

Ontario

During July the Nipissing high-grade mill treated only 37 tons of ore; the low-grade plant treated 6960 tons. The output was $179,998 from the mine. Two machine-drills are working on surface veins uncovered by the hydraulic plant. One assays 3000 oz. over two inches. No. 150 shaft has been closed, as results were not favorable. No. 80 was re-opened.

The Genessee Mining Co., composed of Rochester, New York, people, is to re-open the old United States Cobalt mine, north of the Chambers-Ferland. The 60-ft. shaft is to be sunk to the contact, about 400 ft. deeper. Work was stopped in 1906.

On September 1 the Dome company will pay a quarterly dividend of 5%.——A syndicate of McIntyre shareholders has purchased control of the Pearl Lake mine. The same people are said to be negotiating for the Jupiter.——Diamond-drilling will probably be started at the Preston East Dome shortly.——The West Dome may be organized as the West Dome Consolidated, and work resumed.

Molybdenite is being mined and shipped from a property near Renfrew.

Lumbermen at North Cobalt, who use Mill creek and Cross lake for floating logs to their mill have filed application for damages against the companies that discharge their mill residue into these waters. The lumbermen claim that the tailing damages their logs, also the standing timber. Mr. Haultain, professor at the University of Toronto, has acted as arbitrator in the dispute, and his report is now in the hands of those concerned.

PERSONAL

James W. Neill is in town.

Harley E. Hooper is in Burma.

D. M. Riordan is in New Mexico.

Henry E. Wood, of Denver, is here.

C. B. Lakenan has been in New York.

Hennen Jennings is at the Clift hotel.

H. P. Henderson, of New York, is here.

William Roberts is in Eastern Siberia.

A. C. Ludlum is expected from New York.

Baron Alfred De Ropp is here from New York.

T. P. Sharman has returned to London from Colombia.

Allen H. Rogers has returned to New York from Burma.

F. M. Ayer is manager for the Wild Goose Co., at Nome, Alaska.

S. K. Bradford has arrived from Mazatlan and is now at his home at Palo Alto.

W. B. Blyth has resigned from the staff of Bewick, Moreing & Co. to go to Rhodesia.

H. C. Dudley passed through San Francisco on his way from Oregon to Wyoming.

A. Charles Meagher, recently with H. Kenyon Burch at Miami, is in San Francisco.

Robert T. Hill passed through San Francisco on his return from New York to Los Angeles.

Philip Wiseman passed through San Francisco on his way from St. Paul to Los Angeles.

Howland Bancroft sailed from New Orleans on August 11 by the *Turrialba* on his way to Bolivia.

A. C. Brinker, manager of the Buena Tierra mine, in Chihuahua, is taking a holiday in California.

David Cole is to become a resident of El Paso; he is visiting Cananea, and will shortly proceed to Anaconda.

G. D. Delprat, of the Broken Hill Proprietary, is now also manager of the Broken Hill Associated Smelters.

C. H. Munro, who has returned from Colombia, has moved his office to the Hobart building, San Francisco.

A. L. Blomfield, superintendent of the Golden Cycle mill, Cripple Creek, has been a visitor to the Exposition.

W. W. Breen has accepted an appointment as mill foreman with the Shan Tsz Gold Mines Co., in Eldorado county.

William Thum, superintendent of the electrolytic lead refinery at East Chicago, is visiting the western properties of the United States Smelting, Refining, & Mining Company.

The Industrial Accident Commission of California announces that public hearings are to be held to consider the proposed general safety orders for State industries. The first will be at the Underwood building, San Francisco, on August 25, and the second at the Union League building, Los Angeles, on September 3. Employers, employees, and others are represented. Unless good reasons for changes are submitted at the public hearings, the proposed orders will subsequently be made permanent by the Commission. Copies of the tentative general safety orders will be supplied on request from the offices of the Industrial Accident Commission, 525 Market street, San Francisco, or Second and Hill streets, Los Angeles.

Volume VIII of the Transactions of the American Institute of Metals is to hand. With five Bulletins of 56 pages, the publication covers 450 pages. Abstracts will be made in later issues of the Press.

THE MARKET PLACE

Weekly Summary of Metal Prices and Notes on the Markets.

Metal Prices

San Francisco, August 19.

Antimony	35 —35¾
Electrolytic copper	18½—18¾
Pig lead	4.75— 5.70
Quicksilver (per flask)	$90
Spelter	17 —17¼
Tin	37
Zinc-dust, 100-kg. zinc-lined cases	30

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, August 19.—There are no buyers for copper; the lead market is dull; zinc is falling steadily with no buyers.

COPPER

Prices of electrolytic in New York, in cents per pound.

June	13.60	19.75	Dec.	12.75	....

Exports during the last week of July totaled 12,026,139 lb., valued at $2,265,251. Italy received 4,399,329; England, 2,408,582; Russia, 2,017,216; France, 1,477,017; Norway, 1,078,014; and Holland, 381,651 lb. Imports totaled 3,052,279 lb., worth $346,580. Peru sent 1,748,006 and Canada 1,005,216 pounds.

July outputs were as follows: Braden, 2,890,000; Greene-Cananea, 3,000,000; and Old Dominion, 3,199,000 pounds.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.		Average week ending	
Aug. 12	48.25	July 7	48.10
" 13	47.87	" 14	47.56
" 14	47.37	" 21	47.47

Apr.	58.52	50.25	Oct.	51.12	....
May	58.21	49.87	Nov.	49.12	....
June	56.43	49 03	Dec	49.27	....

A large drop in silver was the feature of the week. The rise early in the week was probably due to the San Francisco Mint buying a total of 1,175,000 oz. Of this, 250,000 oz. was purchased from the A. S. & R. Co. at 48.887c., and a similar quantity at 49c. There is a big demand for silver coins.

Normal shipments of metal from the United States to London are 1,250,000 oz. per week; they are now only about 250,000 oz. Cobalt shipped 321,018 oz. in the week ended August 14. The Nipissing refinery produced 550,121 oz. in July. Exports of silver from London to the Orient this year, to the end of July are about 16,000,000 oz. less than in this period of 1914. Rain has been light in the Punjaub district of India, this affecting Indian buying of silver. The monsoon has been irregular.

The U. S. S. R. & M. Co.'s mines in Mexico are at 50% of capacity. A rich development is reported.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Week ending			
July 21	95.00	Aug. 4	95.00
" 28	95.00	" 11	95.00
		" 18	90.00

May	4.91	17.03	Nov.	5.01	....
June	4.84	22.20	Dec.	5.40	....

The U. S. Geological Survey estimates the domestic production of spelter for the first half of 1915 at 207,634 tons, against 177,991 tons in that period of 1914. Adding foreign ore treated here, and secondary metal, the total is 242,000 tons. Apparent consumption was 160,906 tons, an increase of 11,244 tons. Stocks at smelters are 5884 tons

In its second quarter the Butte & Superior company produced 37,780,020 lb. of spelter. The profit was $2,197,153, an increase of $933,996.

The Interstate-Callahan made a profit of $1,126,114 in the second quarter. Joplin concentrate declined $15 per ton last week, prices being from $60 to $85. The U. S. S. R. & M. Co. is buying 25% ore from Utah mines.

TIN

Prices in New York, in cents per pound

Monthly averages.

	1914.	1915.		1914.	1915
Jan.	37.85	34.40	July	31.60	37.38
Feb.	39 76	37.23	Aug	50.20	....
Mch.	38.10	48.76	Sept.	33.10	....
Apr.	36.10	48 25	Oct.	30.40	....
May	33.29	39.28	Nov.	33.51	....
June	30.72	40 96	Dec.	33.60	....

Tin is dull at 33.75 to 34.75 cents. Australian producers are sounding the New York market with a view to sending their tin. The Australian tin is of high grade, two brands superior to Straits.

ANTIMONY

The market has been dull. As in the other metals there is a lack of new business, and pressure to sell Chinese and Japanese has caused prices to decline. The quotations August 12 were 33.50 to 34c., duty paid. Antimony mines on Pine creek, Idaho, are being actively worked.

Eastern Metal Market

New York, August 13.

Except for very brief spurts of activity on the part of electrolytic copper and tin, all of the metals have been continuously dull. In copper the market was established at 18c. for a short time, then demand became sluggish again, and nominal prices declined until 17c. was quoted August 13. The London market much resembles that in New York, in that there is weakness on every side. The chief hope for copper is a renewal of exports, which lately have not made a good showing, and in the development of needs on the part of the munition manufacturers in this country. Zinc has continued to decline, although prompt deliveries are not easy to obtain in large quantities, some of the producers being sold up. On the other hand, dealers are willing to let go of metal they bought at the recent high prices. They have been waiting for the market to turn upward, as it will with any considerable show of interest on the part of consumers. The principal lead interest has reduced its quotations repeatedly, and independent sellers have not only followed but have given concessions. Lead which was bought at a high price has been sold at a substantial loss. Tin saw a flurry of activity when the price became attractive at 34.62½c. Antimony also lacks new business and quotations are weak. Aluminum is firm and in the best position of any of the metals.

In iron and steel, the feature of the past week has been the purchasing of large quantities of steel-making pig-iron at advances of $1 to $1.25 per ton, a natural sequence of the heavy demand on the steel mills in recent weeks. Foundry irons still lag behind, though they, too, show some betterment. Both speculators and founders have tried to buy iron for delivery in early 1916, but without success. The jobbing foundry trade is picking up, but this line is not enjoying anywhere near the prosperity of the steel-makers. In July the unfilled orders of the Steel Corporation increased 250,000 tons, which was 163,000 tons under the increase of June, but shipments in July were much heavier. Additional capacity which was started lessened the unfilled orders. The production of pig-iron in the United States in the first half of 1915 was 12,233,-791 gross tons, against 12,536,094 tons in the same period of 1914. Exports of iron and steel in June totaled 355,829 gross tons, against 143,953 tons in June 1914. Those of the fiscal year ended June 1915, totaled 2,003,798, against 2,076,364 in the same period of 1914. In June 1915, the exports of metal-working machinery totaled $3,735,562, as compared with $1,079,810 for June 1914. Those of the fiscal year just closed amounted to $28,162,968, against $14,011,359 last year. In the ten months ended April 30, the exports of brass sheets totaled 13,100 tons, against 2050 tons in the same period of 1914.

COPPER

Late last week, when electrolytic came down to 18c., a few thousand pounds was bought, but the movement soon came to an end, and it did little more than demonstrate the true level of the market as it existed at that time. Since then the dullness has been as pronounced as it was before the flurry. Prime Lake was sold to a limited degree at 20c., and a carload or two is said to have been sold under 20c. It is evident that unless conditions change the quotations for Lake and electrolytic will be on a par again. Despite falling prices, it is generally agreed that copper has a basis which is fundamentally strong. The ordinary domestic consumption is not good, although improving. The War consumption shows no decrease, and there is every likelihood of an increase when the great war contracts for munitions are further advanced. In many cases large plants, especially those newly constructed, are not yet in readiness for manufacturing. A great many conjectures are heard as to the cause of the present lull in the market, which at the present time is so quiet that prices are only nominal at best. From 17.87½c. cash, New York, August 9, electrolytic has declined to 17c., the quotation on August 13. Experienced traders point out that heavy buying cannot be maintained at all times, and that some of the consumers who bought heavily on the rise of the market are comfortably supplied until September, at least. The London market has been dull and weak. The exports August 1 to 14 totaled only 8128 tons. English interests recently have made shipments of copper for refining in the United States. Reports as to Germany's supply vary all the way from a statement that she has plenty of the metal, to a cable that the German government has ordered the conservation of all copper cooking utensils. The fact is that nobody knows except the Germans themselves.

ZINC

Both London and New York have been dull with quotations steadily declining. Between August 2 and 11, the London market dropped over £27. It stood at £65 August 11, against £100 a few days ago. The New York quotation for prime Western on the same day was 14.25c. On August 13 it was 12.75c. Strangely enough, though quotations have dropped so steadily prompt metal is not easy to secure, and the entire tendency is simply a manifestation of the severity with which consumers are letting the market alone. Dealers are offering more freely. Brass mill spelter is proportionately lower at from 18 to 23c. Sheet zinc was quoted August 11 at 21c., f.o.b. smelter, a figure entirely out of alignment with the present quotations for spelter. Substitutes for sheet zinc are still being sought. There has been a good demand for sheet zinc for ammunition boxes. Exports to August 14 totaled 2414 tons.

LEAD

In a dull market the quotations for lead have pursued a downward course. The A. S. & R. Co. reduced its New York price August 7 from 5.25 to 5c.; on the 9th to 4.75c., and on the 10th to 4.50c. Following all of the recent reductions of the leading interest, independent sellers, both dealers and consumers have offered the metal at concessions. On August 4 when the big interest was asking 5.25c., two or three carloads were sold at 4.75c., but the general asking price at that time was 5c. With the A. S. & R. Co. quoting 4.50c., outsiders ask 4.45c. Deliveries of lead which was purchased in the frenzied rise of a few weeks ago, are still being made at a heavy rate, and some of this metal is being re-sold at losses. The situation is one where buyers sent the market up on themselves and now are bringing it down, to their cost. New York and London prices are nearing a parity. There is no question but that the large producers are anxious of resuming exportations inasmuch as foreign sales are needed to absorb American production. But little American lead has been offered in London of late, while Australian metal has been sold in considerable quantities. London on August 10 was down to £21 17s. 6d., equal to 4.53c. c.i.f., London. The exports to August 14 totaled 791 tons.

TIN

A week ago it was intimated that the price of tin was getting to a point where it must become attractive to consumers regardless of their being well supplied, and the situation culminated in a good buying movement on August 3. Between 500 and 600 tons changed hands on that day, with the sales mostly in far distant futures, with a sprinkling of spot and nearby deliveries. The buying started when the price touched 34.62½c. The new York quotation for spot, August 13, was 34.50c. The London market is extremely dull and uncertain. There has been some good buying at the Straits, partly on account of the Steel Corporation, and the price at Singapore August 12 was £6 10s. higher than the London market.

BOOK REVIEWS

Purchasing. By C. S. Rindfoos. P. 165. Index. McGraw-Hill Book Co., New York, 1915. For sale by Mining and Scientific Press. Price $2.

The purchase of mine supplies is very important. On the price paid often depends the quality, and subsequent effect on operating costs. The knowledge of how to buy, and at the lowest price, is not learned in a day. Terms are often desired in purchasing, and favorable terms are important. Quick delivery is usually necessary for mine stores. A purchaser should possess a personality as well as knowledge of his business. All of these points, and others, including departmental organization, and forms of purchase are discussed in this book on a subject of which little has been written.

Chemical German. An introduction to the study of German chemical literature. Second edition. By Francis C. Phillips. P. 252. Index. The Chemical Publishing Co., Easton, Pennsylvania. For sale by the Mining and Scientific Press. Price $2.

A number of noted German chemists have contributed to this work. It includes rules of nomenclature, exercises for practice, vocabulary of German chemical terms (54 pages) and others used in German technical literature. Readers of Classical German often find difficulty in mastering German scientific terms, many dictionaries not giving correct meanings of the terms. Many chemicals are made only in Germany, and an understanding of them is necessary. The book under review should prove of value to many chemists in America.

Determinative Mineralogy. By J. Volney Lewis. Second Edition. P. 155. Ill., index. John Wiley & Sons, Inc., New York, 1915. For sale by Mining and Scientific Press, San Francisco. Price, $1.50.

This book is written to be used in connection with some treatise on descriptive mineralogy. The determinative tables are well arranged; the re-statement of tests that accompany each page are especially convenient. Novel reactions are given for copper, nickel, tin, and tungsten; that for cassiterite with hydrochloric acid and zinc is well adapted for use by prospectors. The book could be made much more useful to students by giving type minerals to illustrate the various lusters, structures, bead tests, and other physical and chemical qualities. Ozokerite, amber, wurzilite and a few other hydrocarbons might well have been included. An unfortunate omission is the failure to give a detailed account of the use of the tables through the determination of several illustrative minerals. The cursory laboratory record given on page 64 is woefully inadequate. The index is scanty, a few minutes examination shows the absence of luster, streak, specific gravity. A short bibliography of a few of the many books that have been written on determinative mineralogy should have been included.

RECENT PUBLICATIONS

Products and By-Products of Coal. By Edgar Stansfield and F. E. Carter. P. 51. Charts, Department of Mines, Ottawa, 1915.

Year Book of the United States Department of Agriculture, 1914. P. 715. Ill., index. Washington, D. C., 1915. A number of interesting papers, with 53 plates and 45 text figures combine to make a valuable volume on a basic industry which employs over 50% of the population, and produced crops and animals worth $9,872,936,000 in 1914.

Report on Mining Operations in Quebec in 1914. P. 151. Index, Department of Mines, etc. Quebec, 1915. The value last year was $11,732,783, a decrease.

Abstract from Annual Report of the Department of Mines of Kentucky for 1914. By C. J. Norwood and assistant inspectors. P. 40. Lexington, Kentucky.

An Investigation of Iowa Fire Clays. By Milton F. Beecher. Bulletin 40. Engineering Experiment Station of Iowa State College of Agriculture and Mechanic Arts. P. 117. Illustrated. Ames, Iowa.

The Coking of Coal at Low Temperatures, with Special Reference to the Properties and Composition of the Products. By S. W. Parr and H. L. Olin. Bulletin 79. P. 39. Illustrated. University of Illinois Engineering Experiment Station, Urbana, 1915.

State of Connecticut State Geological and Natural History Survey, Hartford, 1915:

Central Connecticut in the Geologic Past. By Joseph Barrell. Bulletin 23. P. 44. Illustrated.

Triassic Life of the Connecticut Valley. By Richard Swann Lull. Bulletin 24. P. 285. Ill., maps, index.

U. S. Bureau of Mines, Washington, D. C., 1915:

Production of Explosives in the United States in 1914. Also notes on coal-mine accidents due to explosives. Compiled by Albert A. Fay. Technical Paper 107. P. 16.

Occurrence of Explosive Gases in Coal Mines. By N. H. Darton. Bulletin 72. P. 248. Ill., maps, plans, index.

Building and Ornamental Stones of Australia. By R. T. Baker. P. 169. Ill., map. Published by authority of the Government of New South Wales, Government Printer, Sydney, 1915. Australia contains many deposits of granite, marble, limestone, basalt, and other rocks suitable for building, and this excellent work shows sections of them in colors, and many buildings erected. The lithographic work is the best we have seen.

U. S. Geological Survey, Washington, D. C., 1915:

Production of Chromic Iron Ore in 1914. By J. S. Diller. P. 15.

Production of Slate in 1914. By A. T. Coons. P. 14.

Production of Mica in 1914. By Douglas B. Sterrett. P. 11.

Recovery of Secondary Metals in 1914. By J. P. Dunlop. P. 9.

Production of Mineral Paints in 1914. By James M. Hill. P. 20.

Sulphur, Pyrite, and Sulphuric Acid in 1914. By W. C. Phalen. P. 19.

Production of Fluorspar in 1914. With a note on cryolite. By Ernest F. Burchard. P. 7.

Silver, Copper, Lead, and Zinc in the Central States in 1914. Mines report. By B. S. Butler and J. P. Dunlop. P. 98.

Ground Water in Paradise Valley, Arizona. By O. E. Meinzer and A. J. Ellis. Water-supply Paper 375-B. P. 75. Ill., chart.

Geology and Mineral Resources of Kenai Peninsula, Alaska. By G. C. Martin. B. L. Johnson, and U. S. Grant. Bulletin 587. P. 243. Ill., maps, plans, index.

Guidebook of the Western United States. Part A. The Northern Pacific Route, with a side trip to Yellowstone Park. By Marius R. Campbell and others. Bulletin 611. P. 212. Ill., maps, index. Price, $1 from the Superintendent of Documents. The first of this series was reviewed in the Press of July 17.

New Machines and Devices

Information based on letters and catalogues from manufacturers.

Westinghouse Exhibit at the Exposition

A large and attractive exhibit has been arranged in the Palace of Transportation at the Panama-Pacific Exposition by the Westinghouse Electric & Mfg. Co., of East Pittsburg, Pa. It includes one of the Pennsylvania railroad electric locomotives mounted on a turn-table under the centre of the dome of the building at the junction of the two main aisles, thus bringing it in full view of visitors. The turntable is 65 ft. long, and weighs 440,000 lb., including the locomotive. The height of the track is 12 ft. above the floor. Steel ties are used, a new type of construction for this class of work. The foundation was described in the March issue of *Western Engineering*. By means of 10-hp., 3-phase, 220-volt motor, the turn-table revolves once in three minutes. The direction of rotation can be reversed. An unusual method of collecting the current for lighting the locomotive is employed. This was designed by the Westinghouse engineers and involves bringing the leads

WESTINGHOUSE ELECTRIC LOCOMOTIVE.

up through the centre bearing to collector rings, thus obviating the use of third-rail shoes or trolleys. The locomotive is arranged and lighted so as to permit the people to pass through it and inspect the equipment. This locomotive is said to be the largest in the world in passenger service. It consists of two units and weighs 156 tons, and is the first side-rod gearless locomotive ever placed in service. It is equipped with two motors having a total capacity of 4000 hp., and Westinghouse unit switch-control equipment of the HBF type which has made the great record of 99.549 miles per train minute. Statistics show that twelve million passengers are transported annually over the electrified terminal of the Pennsylvania railroad from Harrison, New Jersey, to Pennsylvania station, New York, by these locomotives, which are capable of attaining a speed of 60 miles per hour with full train.

In addition to the locomotive, the newly developed types PK and HL control for railway motors are shown in operation. These control equipments will operate motor-racks equipped with 40-hp. motors. The PK control operating head can be applied to any standard type K controller.

A complete line of commutating-pole railway motors, including box, and split frame types for various voltages from 600 to 1500 are also shown, and in addition a preliminary sample of the new pressed steel railway-motor.

In the Palace of Machinery the firm has an extensive exhibit. It includes the following: domestic motors, fans, and heaters; lamps and fixtures; transformers and motors open for inspection; single-phase motors; variable-speed alternating motors; induction motors; motors with forged-steel frame; back-geared induction motors for low driving speed, with rawhide pinion and steel spur wheel, now used largely in driving stamp-mills, etc.; enclosed direct-current motors; semi-enclosed direct-current motors; direct-current reversing motors for tool machines; vertical direct-current motors; direct-current elevator motors with semi-magnetic elevator controller; direct-current commutating-pole mill motors for the severest service; rheostats; Westinghouse Sirocco blower; Westinghouse Le Blanc low-level jet-condenser; and a Westinghouse-Parsons steam turbine (open for inspection) reaction type blading and impulse wheel direct-connected to a 652-kva. generator and 15-kw. direct-current exciter.

Commercial Paragraphs

In Bulletin No. 130, the CHICAGO PNEUMATIC TOOL CO., discusses the importance of lubrication of pneumatic tools.

At a meeting of the directors of the AMERICAN LOCOMOTIVE CO., New York, held on August 11, J. O. Hobby, Jr., was appointed treasurer of the company.

Catalogue H-2 of 64 pages, published by the LEA-COURTENAY CO., Newark, New Jersey, describes the various types and sizes of centrifugal pumps manufactured by the firm. The design of some of the pumps is interesting.

In Bulletin No. 1093 the ALLIS-CHALMERS MANUFACTURING CO., Milwaukee, describes its engine type direct-current generators. Pictures show the parts of the machines. Several large engines are driven by gas engines. A variable-speed motor driving an A.-C. mine hoist is shown.

Electric steel and electric furnaces will be shown at the Foundry and Machine Exhibit at Atlantic City, September 25 to October 1, when an electric furnace of the SNYDER ELECTRIC FURNACE CO., Chicago, will be in commercial operation, melting cold scrap and pouring three times each day. Tests will be made of the castings.

On and after August 10, the PACIFIC TANK & PIPE CO., of Portland, Oregon, will be known as the National Tank & Pipe Co., (incorporated in the State of Oregon.) The personnel of the new corporation remains the same, namely, Wm. E. Hampton, F. M. Kirsch, H. P. Sackett, Walter Carnes, B. C. Seydel, H. D. Coale, L. E. Long, and J. W. Willis. They have made the name Pacific Tank & Pipe Co. synonymous with quality for the past quarter of a century and will still direct the policy and business of the new company, and their endeavor will be to make the National Tank & Pipe Co. occupy the same high plane.

The MORSE BROS. MACHINERY & SUPPLY CO., Denver, Colorado, has opened a machinery exchange department. On account of the many changes in treatment, machinery is often displaced by other because it is not suitable to the problem in hand. This machinery at another mine or mill may be just what is needed. Mines are requested to send the firm lists of anything available, with the price asked, and it will be listed and advertised without expense. Those wishing machinery should state their requirements, as it is possible that at some mine near to them is the plant they are looking for. A considerable saving is often made in freight as well as in the purchase price. This department will handle goods that on account of distance cannot be purchased and shipped to Denver.

EDITORIAL

T. A. RICKARD - Editor

NAMES are often queer misfits, in persons and in things. Thus the Butte & Superior Copper Company produces no copper, while it is a generous producer of zinc. This fact will make some indexes look foolish in years to come, if not now. We note that the old tailing-heaps of the Butte & Superior are to be reworked. Many pre-flotation dumps will prove mines of metal, by aid of flotation.

CANANEA is on a silver basis; Nacozani and El Tigre are to follow suit. The mining companies operating in these three localities purpose making their pay-roll payments in silver currency, much to the satisfaction of their Mexican workmen. Paper money in Mexico is a thing of ridicule just now, hence the silver peso is in the ascendant. Steps to restore order in Mexico will have to include some wise adjustment of the money problem. Cananea gives the hint.

SLACKENING of purchases of metals, in anticipation of lower prices, has depressed quotations for copper, zinc, and lead, as is shown by our New York correspondent's report. This weekly summary of the metal market will be found interesting and reliable by all those engaged in producing and selling metals. We give consumers' prices, not those of the metal-brokers and selling-agencies. It is probable that a recovery will be manifest shortly, for enormous orders for munitions have been placed in this country and these will require big tonnages of the base metals.

SUGGESTIONS that a mining engineer must express an opinion on the origin of the ore in a mine upon which he reports appear occasionally, as in a recent article in *The Mining Journal*. While some intelligent notion of the genesis of the ore deposit may aid the engineer in his estimate of the probabilities of further ore being found in the mine, it is extremely dangerous for a man to allow any theory to prejudice his observation of the facts. When interstellar ether and solar energy are brought into an article on the subject of mine appraisal, we venture to protest against the absurdity.

ZINC, according to the Geological Survey's semi-annual statistical report, has been produced to the amount of 242,000 tons during the first half of the current year, compared with about 190,000 tons in the previous six months. Thus the rate of production was 484,000 per annum, but the rate for the current six months is increasing by reason of new retorts coming into operation. At the end of June 127,000 retorts were in use, while 32,000 more have been completed since then, representing an increase already of 25%. Thus our earlier estimate of production at the rate of 550,000 to 600,000 tons of zinc by the end of 1915 is confirmed.

THE Federal Government of Australia has taken steps to create an Australian Metal Exchange under its own control. No metals or metallic products will be allowed to leave the country unless they are sold in Australia under precise rules and regulations. None but registered members of the Metal Exchange will be allowed to buy, and no persons will be registered unless the Government is satisfied that the applicants are pro-British and that their applications are in good faith. The Amalgamated Zinc Company was allowed to send 50,000 tons of zinc concentrate to the Edgar Zinc Company, at St. Louis. The price of sale was given as $46 per ton delivered at Mobile, Alabama.

THE RANKIN-WESTLING system of ore treatment will soon be tried on a large scale at the $250,000 plant of the Nevada-Douglas Consolidated Copper Co., which is expected to start about the first of October. This process consists in the treatment of unroasted copper-sulphide ore with dilute nitric acid and, if necessary, some sulphuric acid, in a digester under a 10 to 20-lb. pressure per square inch, at a temperature of 100° C. Air is blown through the digester at the rate of 110 to 135 cubic feet per minute. The process dissolves the copper, which will be precipitated by scrap-iron or electrolytically. As there has been much discussion as to the practicability of this process, its operation at the Nevada-Douglas plant will be watched with interest.

MEXICAN affairs progress but slowly. Carranza's generals and governors have echoed his pious belief that the government of the First Chief of the Constitutionalist party is above reproach and is quite capable of restoring order in Mexico. Villa, Zapata, and their henchmen are willing to be good and to agree to a general conference. Five independent governors also are amenable to Mr. Wilson's proposal, as supported by the South American governments. Border affrays continue to furnish sensational headlines in the evening papers on days when no large vessel is torpedoed. We await the development of events. Meanwhile the warring factions represent about 2% of the 15,000,000 people in Mexico and of these belligerent persons not more than a fifth are actually fighting. Yet, on their account, the rest of the country is exposed to the pestilence of the unburied dead, to the encroachment of

famine and of a lawlessness without hope. Apparently Carranza is the chief obstacle to a settlement. He is probably a sincere reformer, but narrow-minded, pompous, and intensely jealous of foreigners. Moreover he appears to lack the instinct of leadership, namely, the ability to inspire loyalty in his lieutenants. On the whole, the First Chief is an awkward customer, and nothing much can be done until he is either placated or eliminated. How strong he is cannot be ascertained by listening either to him or to Villa. The Administration at Washington ought to be fully aware of this, for it has sent various representatives from time to time on excursions of enquiry. Mr. Wilson must be well informed, whatever he may have lacked in knowledge of Mexican affairs when he first tackled the thorny problem. Patience is a virtue hard to practise, and if peaceful coercion succeeds the President will have done a great thing. But time is not unlimited. The Mexican tangle must be unraveled before the European war ends, and as much sooner as possible.

PROTESTS are being made in Peru against the export tax on mineral products. Of the total exports 47% comes under this category. It is claimed that mining more than any other industry is civilizing the Indian and is educating the natives generally. In the mining districts a notable improvement in methods of living is apparent. Influx of foreign capital has contributed to the welfare of the country and stimulated private enterprise. Not only would an export tax be an unprovoked hardship on the mineral industry, but even the threat of it is injurious to established business. It is urged therefore that the suggestion be killed and that an explicit assurance be given that the industry will be immune from such an embargo for at least 20 years.

TO Mr. E. P. Mathewson and the Anaconda Copper Company we are indebted for a short, but most timely and interesting, article on the operation of the flotation plant in the Washoe works. The kerosene-sludge mentioned is, we presume, the residuum obtained in the refining of oil. It contains as much as 50% sulphuric acid and is a by-product of little value to the oil companies themselves but of immediate usefulness to the flotation metallurgist. A copper-mining company in California asked recently for a price on this oil-acid residuum and was offered it at 16 cents per gallon by one oil company, but later obtained a quotation of $4.50 per ton from another oil company. The use of wood-creosote reminds us that Carnegie tar, the by-product from coke manufacture, is suitable in flotation, when thinned by a lighter oil. The adoption of Hardinge mills is significant, for it may be assumed that the choice is the result of careful tests. So is the expressed intention to employ steel balls and a manganese-steel lining in the tube-mills. That is in accord with the experience at Inspiration, where it has been proved that steel balls are more effective than pebbles, yielding a better product and saving power. The Callow cells for cleaning are a feature of American flotation practice, and we are giving away no secret when we state that this type of apparatus was invented independently and previously by Mr. T. J. Hoover when he was with the Minerals Separation company. At the time it was not deemed worth while to patent the design. Subsequently Mr. J. M. Callow hit upon the idea without any knowledge of the facts just recorded. The method of adding the reagents in the Washoe flotation plant is unique, as Mr. Mathewson says. We direct attention to his description of the revolving discs whereby the feed is regulated. The use of the Oliver filter for draining the flotation concentrate is an adaptation from cyanide practice. Any difficulty in the treatment of the concentrate itself is avoided by passing it to the reverberatory furnace. Apparently the old water-concentration mill at Anaconda is being replaced in sections without any serious interference with regular operations. We hope to give further details at an early date.

Concentration of Copper Ore by Flotation

Most of our readers are aware that the extraction of copper by the usual method of gravity concentration, however elaborated, has averaged not more than 70%. Such a result is a metallurgical failure, even if the incompleteness of the recovery be hidden by the cheapness of the process when applied on a big scale to immense bodies of low-grade copper ore. In short, it represents the temporary waste of a natural resource, to the detriment chiefly of the present owners of the mines rather than to the loss of the community as a whole, for the discarded residue may be re-treated profitably at a later date, as is being done at Anaconda. There a high recovery is being made from 2000 tons of tailing daily. While the surface of such discarded residues may be so oxidized as to allow of the copper being dissolved and removed by rain-water, it appears that this natural leaching effect is superficial, so that it does not penetrate the mass of a dump, unless we grant a period of time measurable geologically. In the effort to improve the extraction, the eye of the metallurgist or millman has been focussed upon the saving of copper in the slime, the needlessly fine product produced in the attempt to grind the ore to a degree sufficient for the separation of the metallic particles from the associated gangue. This expectation was doomed to repeated disappointment because the sliming of the copper sulphide, chiefly chalcocite, put a large proportion of it in a condition definitely beyond the reach of gravity methods of concentration. Thus the tendency in current practice turned to the avoidance of sliming, so that the main desideratum became the liberation of the metallic particles in a granular form. This, of course, led to careful crushing in stages, and multiple-stage concentration, assisted by an elaborate system of screen-sizing and so-called hydraulic classification, all of which entailed a high cost of construction per unit of capacity but large dividends from the low-grade deposits uncovered during recent years.

Indeed, it was believed that the art of dressing copper ores, especially those of the disseminated chalcocite type, had begun to crystallize into its final form and some learned authorities sought to record the 'laws' governing these operations and to standardize rules for the achievement of their purpose. But the 30% loss compelled furious thinking and checked over-confidence among the more seriously minded. In his perplexity the metallurgist turned to leaching methods and for a while we began to think, with Disraeli, that sulphuric acid was the ultimate measure of industrial prosperity. Several new processes, and more old ones in new guise, had just caught public attention when flotation, long obscured in the fog of patent litigation on the other side of the Atlantic, came into prominence. It was not the old bulk-oil process, nor the surface-tension method, but flotation by froth. Success was immediate, as applied to copper ores, in Montana and Arizona, for example. The newest process had the important advantage of being able to select and recover the copper in the slime that had been beyond the reach of water concentration. In fact, that part of the metal-contents in sulphide form that had been farthest from the reach of gravity methods was found to be the product most easily within the grasp of the frothing treatment. This departure immediately made possible great simplicity of plant and machinery in the treatment of such ores as were amenable to the process. Moreover, since firing with coal-dust has made reverberatory smelting more economical than blast-furnace practice, the various stages in crushing and concentrating can be greatly reduced and simplified. Reverberatory furnaces require a fine feed and yet do not entail loss by dusting, thanks to electric precipitation of that ancient nuisance, so that with the aid of flotation there is no longer any hazard in the sliming of the sulphides that are amenable to the process, either through excessive loss in mill-tailing or by escape in roaster-dust. In short, the making of slime is now safe and sane. Among factors contributing to this epochal result, namely, the simplifying of concentration plants, is the introduction of the Butchart form of riffle, a modification of the Wilfley, and the recent recognition of the superiority of the tube-mills and ball-mills over rolls or stamps in preparing ore for concentration. Another discovery concerns the advantageous use of steel balls instead of flint pebbles in tube-mills. In cases in which the ore has a ratio of concentration, say, between 3 : 1 and 10 : 1, it may prove necessary to use three stages in separating the mineral, but when the ratio of concentration is higher, as at the disseminated copper mines, the stages of concentration may be reduced to two, not counting that done in the closed circuit. It is now possible, as suggested by Mr. David Cole in the February bulletin of the American Institute, to take run-of-mine ore, (1) pass it through a primary crusher, (2) run the product into a ball-mill of large capacity running wet and reducing to $\frac{1}{4}$ inch, (3) pass this product, without classification or screening of any kind, to Butchart riffles, (4) the tailing from which goes to re-grinding machines, such as pebble or ball mills, (5) the product of these being sent direct to a frothing machine, which is also a classifier, the first spigots removing the coarse material from the frothing machine across a table riffled *à la* Butchart and returning it to the grinding machine. This establishes a closed circuit in which the undersizes removed from the closed circuit are controlled by the operator of the frothing apparatus to the point yielding the most economic result. All the material that passes out of the closed circuit has been exposed to thorough frothing, and therefore carries none of the very fine slimed copper sulphide that formerly was lost. Everything not fine enough is retained in the closed circuit, so that only the slime and fine sand, the former free from sulphides, are able to escape. Thus the classification by frothing becomes the crucial part of the whole system of treatment, and the development of this form of flotation machine becomes an important step in the new metallurgy of copper.

Shares of No Par Value

In order to develop a mining 'prospect' it is necessary to raise capital. The most convenient method of getting this capital is by forming a stock company and selling its shares. Local mining men are usually the first buyers of such shares and when buying them know perfectly well that they risk losing their money. Hundreds, if not thousands, of such companies have been formed within the last few years and their shares sold to such open-eyed buyers. This perfectly above-board legitimate mining business sets the wheels of mining industry spinning and often results in developing mines that pay taxes, dividends, wages to workmen, salaries to engineers, and furnish a market for supplies and machinery, besides producing the metals needed by a material civilization. The incorporation of a mining company, such as is required for financing a 'prospect,' is a simple matter; the total expense of the incorporation in many of the Western states need not exceed $100; this sum will cover the State fee for incorporation, the cost of a seal, a sheaf of stock-certificates, and an account-book for the secretary. No lawyer is needed for these small companies. In consequence, in the boom days companies were formed on small, or no, provocation and their name was legion. Although there was no difficulty in forming a company, yet before any shares could be sold a serious difficulty had to be overcome. The trouble was that the shares could not be sold unless the company owned property the value of which was equal to its capitalization. For example: take the case where the property cost only $5000, while the company, as is usual in the West, had a capital of $1,000,000 in 1,000,000 shares, each with a par value of $1. Before any shares could be sold, the secretary, or some other official of the company, had to certify that the property was worth $1,000,000. This certification of a fictitious value was a stumbling-block to a conscientious secretary, but his worry was relieved by reflecting that the performance was a mere matter of form and that 'everybody's doing it.' Such perfunctory certifications were required in Nevada in 1907 and in other States, and it was prob-

ably to avoid a similar condition that the Railway Commission of California recently suggested that mining shares should have no par value. Remembering that the last California legislature passed 770 new laws, it is too much to expect that anyone can be sure of the present legal requirements.

The issuance of mining shares without par value has been often advocated by mining engineers, but the Kennecott Copper Corporation seems to be the first important company to have been formed on this basis. The shares of that company are now selling for $34 on the New York Curb. The only novelty about these 'no-value' shares is their adoption by a modern mining company. Cornish mines have been run for several hundred years on the cost-book system, in which the 'adventurers' paid losses or divided profits according to the results of the mining operations during monthly periods. No shares were used. Similar methods have been employed in other industries, notably by whalers, in which all worked for a share of the profits, the so-called 'lay,' which might vary from the captain's quarter to the 1 180th part for the greenhorn before the mast.

This idea of not fixing the par value is sound because at best the price of the shares as named at the start of a mining enterprise represents only a nominal valuation of the mine itself. Indeed, the share-valuation of a mining company bears only an indirect relation to the appraisement of the mine. The quotation for shares depends upon the excess of buyers over sellers, or the reverse; it may represent a sum much above or far below the actual wealth realizable from the ore in the mine. Therefore it would be well to express the assured profit by one kind of capitalization and the possibilities of further profit by another kind of capitalization. For example, we understand that Mr. A. C. Beatty suggested to Mr. Daniel Guggenheim that the assured profit in the Yukon Gold alluvial properties should be capitalized in the form of bonds, while the probabilities and possibilities of future development should be expressed by an issue of shares of no par value. If that had been done the Yukon Gold would have issued bonds for an amount equal to the profit to be won from the known gold resources of the property as ascertained by the examination made by Messrs. Beatty and O. B. Perry, and the 'water' would have been kept clearly separate by an issue of shares the value of which would be left to the vagaries of speculation as affected by future production, seasonal vicissitudes, and the temper of the public. The idea, we think, was good, except as to the designation of the first security. As mining—even the extraction of ore 'proved,' 'assured,' or 'in sight'—is necessarily subject to risk, it is well to recognize this basic fact by using an appropriate form of security. Bonds and debentures have a gilt-edged connotation that is misleading. Preferred shares would be better. These would represent the minimum of risk, for they would have a first call on the profits and a corresponding limitation of earning power, to be fixed at a given percentage (say, 8%) on the par value; while the ordinary shares, without par value, would be so much 'water,' representing the potentialities of the enterprise, and having therefore a bigger risk and the chance of a commensurate gain, both unlimited. The preferred shares would be a speculation so sound as sometimes to be rated as an investment, while the ordinary shares would range from a risky speculation to a wild gamble. As these things are now conducted, the assured and the probable, the possible and the impossible, are so mingled in the share valuation of a mine that the conservative speculator, who calls himself an investor, has little chance to do business on sensible lines. Under such a system a young prospect would be capitalized for shares of no par value, indicating that it had no liquid assets but large expectations, while a property with proved resources would issue preferred stock equivalent to its assured profit and shares of no par value to express the 'water' that by skill, luck, and the bounty of Nature may be turned into golden wine.

An Old Issue

Miners in California will shed no tears over the passing of the Anti-Debris Association, which became defunct on August 18, in consequence of the Sutter Basin controversy. This Association, to prevent hydraulic mining of gold-bearing gravel in the foothills, was supported by contributions from the counties in the Sacramento and San Joaquin valleys. Its moving spirit was Mr. Robert T. Devlin, who, in the proper exercise of his professional function, prepared the injunction suits that irritated the diggers in the Sierras. As a corrective, the California Miners Association was formed, but it also has died a natural death, largely because the hydraulic mining companies left the machinery manufacturers to support it. Messrs. Charles G. Yale and W. C. Ralston, and the late Jacob H. Neff, did yeoman service for the Miners Association and at one time its meetings served to rally the leaders of the mining industry in this State. For obvious reasons we regret that it should have been allowed to expire. Another organization to be mentioned in this connection is the United States Debris Commission, which stood between the two parties in the old warfare waged by the valley-farmers and the gravel-miners. It was organized to exercise control over the discharge and impounding of the tailing from the hydraulic mines. While Colonel W. H. Heuer was in command the Debris Commission was considered fair and reasonable, but of late, since he retired, the Commission has made many drastic rulings, insisting on solid concrete dams and not more than 3% of the silt to go over. This has discouraged the building of dams and put a stop to new hydraulic mining enterprises. The new Government commissioners have slight understanding of, and little sympathy with, the mining industry. On the whole, therefore, it is clear that the State is suffering from both lack of public spirit and interference with reasonable initiative. To those familiar with the alluvial deposits of the Sacramento and San Joaquin watersheds, it seems a waste of natural resources that they should not be exploited, to the gain of many and to the injury of none.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Speculation in Mining

The Editor:

Sir—It appears to me a most important duty of the technical publications and of the mining engineers to endeavor to arrive at a clear understanding of the reasons for the palpable lack of interest of the majority of the general public in mining enterprises.

That all mining enterprises are not a success is no adequate reason; failures occur just as well in all other classes of investment. True, the general public has practically no knowledge of mining, but neither has it a technical knowledge of the various industrial or commercial enterprises to which it confides its capital.

The greatest difficulty under which the mining industry labors is that the general public regards it as a purely speculative enterprise. We mining men may proclaim as much as we please that mining is a legitimate business enterprise, the general outside public refuses to believe it. This is especially remarkable in California, where such a number of financially profitable mining enterprises are carried out, and have been operated for a number of years. The general public apparently never hears of them, and takes no interest in them. "Mining is only speculation," it asserts. Once in a while the fever of speculation seizes the general public, and then it goes at it wildly, with the natural result of many disasters and only a few exceptional successes.

The only remedy I can see is a campaign of education, which will give the public a general comprehension of the bases on which the mining industry rests. This industry covers three entirely different phases: prospecting, developing, and operating mines.

The prospecting for mines involves a great amount of personal hardship; it requires practical knowledge, and the more technical knowledge the better, but, above all, tenacity of purpose and indomitable faith in final success. The prospector is an essential factor in the mining industry, and every action taken to curtail his activity is a great detriment to that industry. This phase, however, requires a small outlay of money and, therefore, comes only slightly in contact with the general public. A prospect only represents the fact that there are surface indications of a possible underlying orebody. Whether these indications are of sufficient importance to justify the outlay of money to ascertain the existence of such an orebody is one of the most difficult problems put to a mining engineer. The data at hand in nearly all cases are far from sufficient to enable him to decide this question; general experience, general knowledge, and local knowledge of the vicinity are the principal guides at his disposal.

The prospect now enters into the stage of development. This stage of the industry demands a serious outlay of money, and as it is to a certain degree hazardous, it is also entitled to large profits, which it invariably receives in case of success, provided the operations be conducted in a business-like manner. The development of prospects into producing mines, although not demanding such large outlays of money as are required to develop and operate big mining enterprises, yet demands such an amount of capital that generally it can be provided only by co-operation. It is imperative for the success of such development enterprises that they be placed in the hands of competent men; experience teaches that the great majority of failures in such enterprises can be traced to the fact that those who provide the capital fail to realize this fundamental principle. In general, work is started with a relatively small force, and to the layman it seems unnecessary to have a high-priced man in charge; a competent mine-foreman or a young graduate from a mining school, whose services can be had at relatively low figure, appear to him fully competent to superintend the small force, because he cannot comprehend that the direction of the work will, in most cases, determine the success or the failure of the undertaking, and that properly to direct those works technical knowledge and practical experience are absolutely necessary.

No mining engineer will claim that he is infallible, in fact, every mining engineer realizes that during the course of his career he has made mistakes, just as any man who has accomplished anything during his lifetime is conscious of having made mistakes. It is only the critic, who has never personally accomplished anything, who is infallible. In this respect the general public is unjust to the mining engineers, any mistake made by them is always brought forward, while their efficient work scarcely receives any public mention; moreover, many mistakes made against their advice are placed at their doors.

Experience teaches that not every prospect, upon development, will answer the requirements of a producing mine. It is therefore not a businesslike proposition to base the financial outcome of a mining enterprise, in the development stage, on the result of the exploration of one property. In such undertakings the principle of divided risk is the only method of safe finance. This requires a larger investment of capital than if only one

property is handled, but the chance of failure is reduced, and the speculative element is, in some degree, eliminated. Such an undertaking will require financial co-operation; but the resulting corporation can be organized on a much sounder financial basis.

Here is a field of action for mining engineers that will not only be profitable to them, but will place the profession in closer touch with the public, and engender a feeling of confidence between the two. Let mining engineers come into such corporations; if not financially able to participate, let them bring their services as an asset. Let the public feel that the interests of their technical co-partners are entirely the same as the interests of those who have put their money in the enterprise; then an atmosphere of confidence in mining enterprises will be created, and the public will realize that to be successful it must rely upon the co-operation of technical men, just as in all other commercial and industrial enterprises.

Another question must be taken into account: To obtain financial co-operation the public must be reached. This is a special line of business. Promotion has a bad reputation, and unfortunately not without cause, as many promoters have misled the public. Still, in nearly all cases, the participation of the public requires the co-operation of these intermediaries. These have for so many years considered mining enterprises as wild speculations, that it will take a campaign of education to get them in a frame of mind to consider mining as a serious business proposition. Mining enterprises based on a sale of stock at 5, or even 25, cents on the dollar are not attractive investments, they require a heavy over-capitalization, and are only acceptable as speculative ventures. The general public must be educated to the fact that mining investments, when properly made, are even safer than commercial investments; this must be pounded into the investing public not only through the medium of technical mining publications, but also through publications that have a more general circulation. It ought to be done by capable financial writers, who at present command on this subject a greater confidence of the general public than the mining engineers, because the public persists in considering the latter as prejudiced. The fact that Bradstreet's and Dun's commercial agencies in their reports show that the percentage of failures in legitimate mining investments is smaller than that in commercial investments, appears as a conclusive argument upon which to start such a campaign of education. This education requires the assistance of writers along those lines, because they alone know how to reach the public. It is a well-known fact that not all financial news reaches the public in such a form as to give it full knowledge.

Summarizing: the education of the public to an understanding of the intrinsic value of legitimate mining enterprises requires a long and persistent campaign, in which the co-operation of technical and financial authorities, with the distribution of facts through the medium of newspapers and magazines, as well as through technical papers, is required.

William Forstner.

Professors of Mining

The Editor:

Sir—Relative to the recent letters on professors of mining, allow me to say that some professors whose main asset is long years of "practical experience" with nose-close-to-the-grindstone, have about as much value as informers on the conditions and peculiar problems of what they were working at, as the average soldier straight from the trenches knows about the war as a whole. This soldier usually says he found the trenches muddy or enjoyed the soup, then he "heard a big noise and woke up to hear the nurse say 'try a little of this'." Being too close to a subject may have an effect like looking at a big wall-map from a distance of two inches; a proper perspective is lacking.

Concentrate: Then and Now

The Editor:

Sir—I read with interest Mr. Ebenstein's article in your issue of August 7, in which he compares the saving made by concentration in some of the older mills with that made by the modern, more up-to-date, plants. As I understand his article, he maintains that jigs, if rightly handled, would result in a better saving of the 'values' and would eliminate the necessity for tables and the treatment of the finer material by flotation.

While I am a strong supporter of the jig, under certain conditions, I have been under the impression that the jig, like every other machine, has its own place in the scheme of concentration and that one may encounter many conditions in which the jig would be out of place. In this connection I would like to ask what saving could be made on an ore averaging 2% copper where a large proportion of the mineral-bearing particles are not freed until crushed to 60-mesh or finer? This example is an actual case of ore now being treated in one of the large mills of the Southwest, the flow-sheet being approximately as follows: native copper removed by jigs at from half-inch to 5-mesh; the undersize from screening system passing over roughing-tables and the rough concentrate cleaned by Wilfleys; the tailing from roughing-tables and Wilfleys are classified, sand coarser than 40-mesh re-ground, the sand treated on vanners and the slime by flotation. Does Mr. Ebenstein contend that jigs alone would successfully handle this ore with a saving of better than 70%?

T. H. Oxnam, Jr.

Globe, August 21.

The treadwell club of employees of the Alaska Treadwell mine has 1500 members, each of whom pays $1 per month. The 12 directors are selected from employees and management. The club has large halls, a complete theatre, a band of 27 pieces, orchestra of 10 pieces, swimming tank, library, billiard tables, bowling alleys, reading and writing-rooms, moving picture shows, gymnasium, and athletic paraphernalia.

Scientific Management, The Utility of Rest Intervals

By W. H. SHOCKLEY

In my daily rounds through the mine I often stood watching Harry Trevethick as with loose swings of his hammer he drilled his holes. Thirty or forty blows of the four-pound hammer before his 'pass' was ended, then a cleaning out of the hole with the scraper, a little shifting of the position and another pass—a graceful rhythmic exercise, broken by frequent rests. He was supposed to work for about four hours, then blast his holes before lunch and to continue the same routine after lunch until the 10-hour shift was worn out.

Actually, however, no such steady work was done and a portion of the shift-boss's duty was to see that the miners did work steadily. Once in going through the mine I found a dozen miners stretched out at full length loafing in a big stope. My Welsh foreman, to whom I reported the incident, seemed more annoyed at my having gone through the stopes "like a monkey" than at the idleness of the men. He had hardly command enough of English to explain his views; perhaps if I had understood him fully I should not have thought it necessary to discharge several of the men for the sake of discipline. My foreman held that in spite of their loafing the men did a good shift's work. As far as I could learn, by comparison with the work done in other mines near us, we had a good class of miners and did as much or more work for the same cost.

Though theoretically a miner was supposed to work as constantly as possible during his shift, yet everybody knew that actually a good deal of time was devoted to resting; during the dozen years or so that I was an active mine manager many men were discharged for being caught while idle. A question that naturally arises from a consideration of the above circumstances is: Can a miner do more work by toiling uninterruptedly, or by taking short rests? Or, as the miners express it: Cannot a man do better work by 'tapering off' at intervals? I have often wondered if the men that I caught lying down in the stope did not do a good shift's work after all. I know of no investigations among miners that cast any light on this problem. Doubtless such investigations have been made, but I have seen no published results.

There is no question but that in many varieties of strenuous human effort the man who sets the steady pace —"the long, low gallop that will tire, the hound's deep hate, the hunter's ire"—will beat the man who makes his most violent effort and then rests. For instance: a man who ran his first hundred yards in ten seconds, then rested, then ran another hundred yards, and so on for a mile would be badly beaten by an experienced mile-runner who set a steady gait from the start. But whether the miner who worked hard and then rested would do more than the steady, though less strenuous, worker is an unsolved problem as far as my knowledge extends.

Taylor, the father of Scientific Management, relates an incident that casts a good deal of light on this subject. He and his fellow-investigators had worked out theoretically that a man engaged in hard manual labor could do more work if such labor was broken by rests so that the laborer is not over-tired. For their experiment they selected "Schmidt," a worker in the yards of the Bethlehem Steel Co. engaged in carrying 12½ tons of pig-iron per day and loading it on a car; the task was to get Schmidt to handle three or four times as much and make him glad to do it. This was done as follows: Schmidt was called out from among the gang of pig-iron handlers and talked to somewhat in this way:

"Schmidt, are you a high-priced man?"

"Vell, I don't know vat you mean."

"Oh, come now, you answer my questions. What I want to find out is whether you are a high-priced man or one of those cheap fellows here. What I want to find out is whether you want to earn $1.85 a day or whether you are satisfied with $1.15, just the same as all those cheap fellows are getting."

"Did I vant $1.85 a day? Vas dot a high-priced man? Vell, yes, I vas a high-priced man."

The rest of the conversation is too long to quote, but in the end Schmidt agreed to pick up a pig and walk, or sit down and rest whenever he was told to do so by a man with a stop-watch.

In his first day's work, under the control of the stop-watch, Schmidt, who had previously handled 12½ tons of pig-iron, loaded 47½ tons, or nearly four times as much, on his car. He had worked 42% of the time and rested 58%.

This was an astonishing result and already has had far-reaching consequences. Certainly, any ordinary superintendent coming on the scene of work and seeing Schmidt carry pigs for five minutes and then sit down and rest for seven minutes would have been very apt to say to his foreman "Fire that man; he's no good! Why he loafs more than half the time." And the said superintendent would find considerable difficulty in believing his own eyes when he saw that the man who worked a little and loafed a good deal was doing four times the work of the steady workers. It is as well to state that this work of Schmidt was not a spurt but was his daily task for a number of years, and the increased work had no bad physical or mental effect on him.

The explanation of Schmidt's ability to load four times as much pig-iron when working with rests as when working steadily is that he did not work long enough

at any one time to get fatigued. This question of fatigue is being ardently studied by psychologists all over the world and is a question of vital importance to Scientific Management. Avoidance of fatigue, however, does not account entirely for Schmidt's ability to load the 47½ tons of pig-iron, for on applying the same system to a gang of 75 men it was found that only one man in eight was physically capable of handling this quantity. But there was no trouble in finding plenty of other men to perform the same task.

While the fundamental laws of Scientific Management are easy to grasp—the basal law, indeed being nothing more than the doing of the most work, with the least labor in the shortest time—the practical application of the laws is an affair of great complexity. To establish the system in any particular business requires much experience and unlimited time. Taylor himself says that the proper way of introducing the system is by beginning with one man at a time and not by trying to influence a number of men at first, for many failures have been made by managers who have tried to introduce the system in a wholesale manner. In the PRESS of August 7 a request was made for information regarding the application of Scientific Management to mining work and it is hoped that this request may elicit some interesting facts.

Although it is likely that most readers of the PRESS are fully conversant with the literature of Scientific Management it seems worth noting that a bibliography of several hundred titles will be found in 'Scientific Management,' edited by Clarence Bertrand Thompson, Cambridge, Harvard University Press, 1914. The best single book on the subject is 'Principles and Methods of Scientific Management,' F. W. Taylor, New York, Harper Brothers, 1911.

Flotation at Mt. Morgan, Queensland

During the six months ended May 30, 1915, the concentrating plant at Mt. Morgan was practically remodeled under the supervision of C. Faul, of the Minerals Separation company. When completed it is expected to treat between 700 and 800 tons per day. The following is the record of the plant for the period:

		Assays.		Recovery.	
		Copper,	Gold,	Copper,	Gold,
	Tons.	%	dwt.	%	%
Ore treated	57,974	2.14	4.92	....	....
Table concentrate	12,696	2.89	10.06	29.60	44.78
Flotation concentrate	4,271	17.17	22.00	59.21	32.92
Total concentrates	16,967	6.48	13.07	88.81	77.70

All products contained 1100 tons of copper and 11,084 oz. gold. Concentration, briquetting, and sintering cost $1.67 per ton of ore treated.

PLATINUM PRODUCTION of the United States in 1914 was 570 oz. This was saved from placer mines in Oregon and California. The Boss mine, Nevada, yielded 110 oz. Russia produced 250,000 oz., Columbia, South America, 15,000 oz., and New South Wales, 1275 ounces.

Sampling Base Bullion

By F. D. WEEKS

*Originally the lead bullion was sampled by taking a dip-sample from the lead-well, which was not satisfactory. The present management built drossing-kettles in which the bullion is stirred by compressed air, skimmed into a Howard press, stirred by hand and siphoned out into bars for shipment, after sampling by dipping 'gum-drops,' approximately ½ A.T. in weight. For some time the results were unsatisfactory. Although the copper had been reduced to 0.06%, the bullion had a dirty appearance, and gum-drops of the same dip would not check with each other, especially as to gold content. Consultation with men versed in the subject did not help. A remedy was finally found when the temperatures were determined by a pyrometer and the difficulties overcome by the following procedure: Take off heavy dross at 900° F., blow until temperature reaches 680° F., skimming from time to time; raise the heat to 720° F. for sampling, and mold at 800° F. Since this method was adopted, little trouble has been encountered.

A plan to eliminate the personal equation in bullion assaying has been carried out for some years, with good results. The gum-drops, weighing about ½ A.T. each, are weighed without trimming, cupelled, and parted; the weights of the gum-drops in decimals of an assay ton, of the gold and silver together and of the gold alone, in milligrams, are reported by the assayer. The calculations are then made in the office on a machine. In this way the assayer is not tempted to make his results check, because until they are figured he does not know whether they will check or not. The excellent results obtained are sufficient reason for following the plan.

Metals Through the Canal

During the fiscal year ended June 30, 1915, the Panama Canal was open for traffic for 10½ months. In that time, 1088 vessels of 5,416,787 gross and 3,843,035 net tons measurement, passed through, carrying a total of 4,969,792 tons of cargo. Metals, ores, etc., carried were as follows, in tons:

Commodity.	Atlantic to Pacific.	Pacific to Atlantic.
Nitrates	411	651,537
Coal	279,064	7,500
Petroleum, refined	220,229	32,199
Iron and steel manufactures	196,234	5,968
Iron ore	2,200	83,904
Railroad material	56,106	.....
Copper	2,810	46,989
Machinery	32,788	954
Oil, crude	3,731	26,863
Tin [probably tin-plate.—EDITOR]	24,286	6,304
Cement	22,637	.....
Iron	21,198	.....
Copper ore	.....	20,740
Coke	20,444	.....
Chemicals	10,302	1,909

*Excerpt from a paper 'The Salida Smelter,' to be presented at the September (San Francisco) meeting of the A. I. M. E.

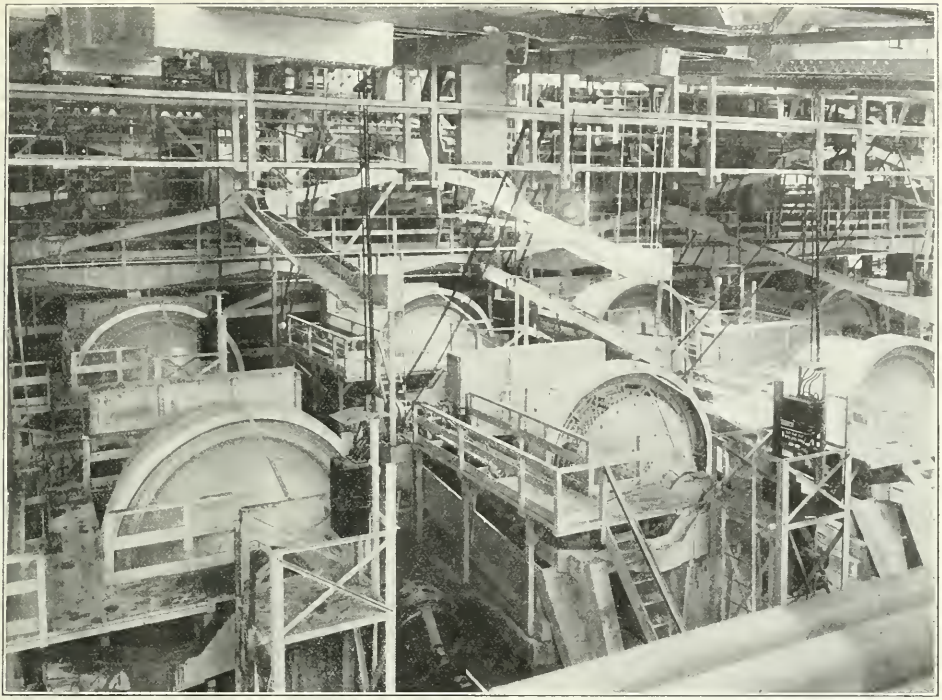

FIG. 1. GENERAL VIEW OF HARDINGE MILLS AND DORR CLASSIFIERS.

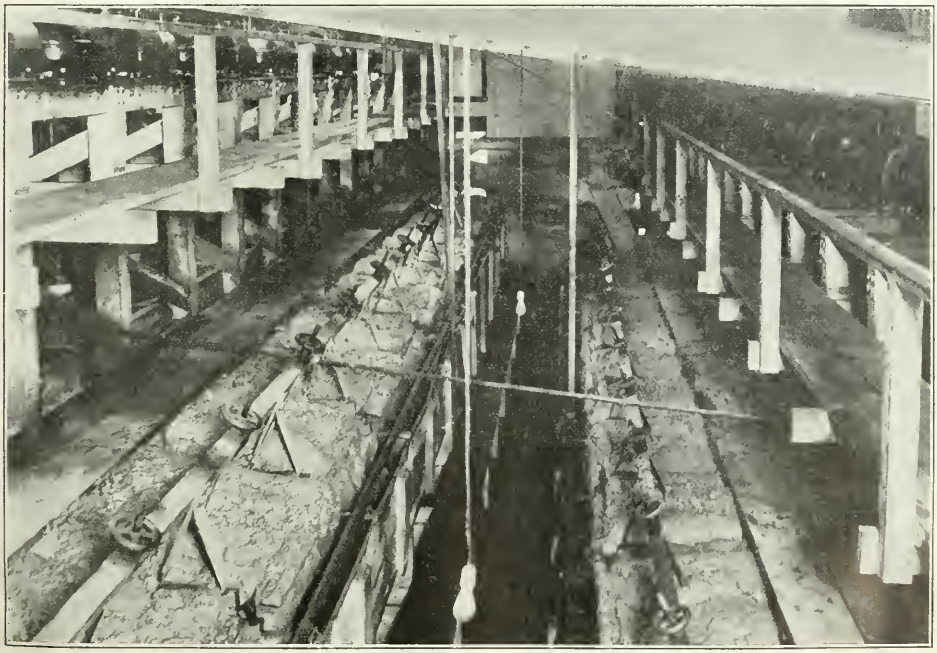

FIG. 2. MINERALS SEPARATION FROTHING MACHINES.

Flotation at Washoe Reduction Works, Anaconda

By E. P. MATHEWSON*

The mineral that is two millimetres and under in size is sent to the Hardinge mills for re-grinding. These mills are 10 ft. long by 4 ft. diam., and are in closed circuit with simplex Dorr classifiers, one classifier to each mill, 6 mills to the section, and 8 sections in the establishment. (See Fig. 1.)

The overflow from the classifiers goes to the flotation division, and the classifier-sand is returned to the Hardinge mills. At present pebbles are being used in the Hardinge mills, but, in all probability, steel balls will ultimately be used. With pebbles the Forbes lining is used, but with steel balls in use, each mill will be fitted with a false wooden lining to reduce the diameter of the cylinder, and a manganese-steel lining will be placed inside of this.

Each mill has a direct-connected 225-hp. motor. The mill fitted with pebbles requires from 95 to 115 hp., but the motors are made extra heavy, in anticipation of the use of steel balls.

In each section of the flotation plant there are four Minerals Separation machines, each having 15 agitators and 14 floating-compartments. Below these are six Callow cells for cleaning the concentrate. The agitators for the Minerals Separation machines are made of gun-metal and are driven by bevel-gears from the main shaft. (See Fig. 2.) Each machine is driven independently by a 150-hp. motor, running at 385 r.p.m. on full load. The speed of the agitators is reduced to about 225 r.p.m.

The product from the machines is a tailing, which goes to waste (from this tailing, fire-brick, building-brick, and acid-proof brick will be made in a new brick-plant now under construction); a concentrate, which is sent to the Dorr thickener-tanks, for settlement—this comes from the first three cells of the M. S. machines. The rough concentrate from the next six cells of the M. S. machines, is further cleaned in the Callow cells. (See Fig. 3), making a clean concentrate; and the middling, which, with the middlings from the remaining five cells of the M. S. machine, is returned to the feed of the M. S. machines.

About 6 to 8 lb. of 50°B. sulphuric acid, per ton of flotation-feed, is used, together with two to three pounds of kerosene-sludge acid and from one-half to one pound of wood-creosote. A portion of the wood-creosote is added to the head of the Hardinge mills, and the remainder is added at the head of the M. S. machines. The pulp is heated to 60 or 70°F. by steam introduced into the first agitating-box. The method of adding the reagents is unique. The mixer consists of a revolving disc, to the circumference of which are attached a number of cups. The disc is set vertically, so that its lower edge dips into the pan of acid, or oil; as the disc revolves the cups are filled, and later discharge their contents into a suitable launder leading to the flotation machines. The disc is driven by the friction of a wheel against another disc attached to the main drive. The wheel is run at constant speed and any variations in feed can be made by changing the point of contact between the wheel and the disc. In addition to the speed regulation, the amount of acid, or oil, fed may be varied by changing the number of cups, or the size of the cups.

On account of lack of space in the old mill, now being re-modeled for flotation, an auxiliary plant has to be installed to handle the extra slime from the mill. This is now under construction and will consist of 20 M. S. machines of the same type as those now in use. Fourteen of these will be required for treating the current slime from the mill; the remaining six will treat old slime from the dump. This will be brought from the dump dry and mixed with water before treatment in the machines. The capacity for the dump-slime is about 1000 tons per day. No Callow cleaners are to be used in this plant.

The concentrate from the flotation machines is thickened to about 60% solid in Dorr tanks, 50 by 12 ft., the spigot-product of which goes to 11½-ft. diam. by 12-ft. face, Oliver filters (see Fig. 4), each having a capacity of about 150 tons daily.

The cake from the filters contains about 18% moisture and will be fed onto a conveyor carrying mill-fine concentrate to the new roasting-plant now in process of construction. In this way the filter-cake will be fairly well mixed with the concentrate, so that a generally uniform feed will be obtained for the roasters.

At the present writing two sections (out of eight) of the old mill have been re-modeled to use flotation; and a third section is now nearly ready. The mill is being re-modeled a section at a time by the company's engineering department. Some remarkably rapid work has been accomplished in changing over from one system to the other. For instance, the No. 2 section of the mill was in operation on the 26th day of May for ordinary water-concentration; but was wholly re-constructed and in operation, using the flotation process, on the 26th day of June. Each section has a capacity of 2000 tons of original feed daily. At the present rate of re-construction the entire plant will be re-modeled by January 1, 1916.

Brass cartridges made from impure material do not keep well, but are apt to crack in storage, especially in hot climates.

Technical Reminiscences—II

By E. GYBBON SPILSBURY

Long drawn-out litigation between mining companies, while of more common occurrence at the present day, was not unknown in the last generation.* An early experience I went through and which gave me considerable reputation at the time may be of interest to the engineers of today.

In order to make the situation clear it will be necessary to sketch the causes that led up to the litigation.

In the year 1852, the Corphalie Zinc company of Huy, Belgium, was second in importance only to the Vieille Montagne company, and was a prominent factor in the ore-markets of the world. Other companies were being formed and started, and consequently there was considerable competition for the purchase of zinc and lead ores. A new source of supply was being developed in the Eiffel mountains in Rhenish Prussia, and among the numerous operations the oldest and best was that of the Saturne company of Bensberg. The Corphalie company was desirous of acquiring the output of the Saturne company, which was of very desirable quality, and was capable of considerable increase. The Saturne company, however, was not financially strong enough to carry out the necessary improvements and applied to the Corphalie company for a loan of 2,500,000 thalers to be secured by a contract for their entire output. It was the wording of this contract that caused the litigation.

The Saturne company had been operating for ten years previous to the signing of the contract. Their mines produced argentiferous galena, and zinc-blende, which latter also carried silver. As the question of the disposition of the lead products never came into serious dispute, there is no need of considering them further in this story.

The contract for the sale of the zinc ores to Corphalie was for a term of 50 years. In order to arrive at a basis for the selling-price, the operations of the Saturne company for the previous 10 years were taken, and it was found that the lowest percentage of zinc in any of their shipments was 28%, while the highest had reached 53%. A sliding schedule, based on the quotations of the Breslau zinc market for the month of delivery, was worked out for each percentage of zinc content between 28 and 53%, it being stipulated that the price for any ores carrying less than 28% zinc or more than 53% should be mutually arranged, if any such grade of ore were produced in the future.

*[Probably the Comstock Lode holds the record for expensive litigation. A special chapter is devoted to the "interminable litigation" in Eliot Lord's 'Comstock Mines & Miners' wherein it is stated that $10,000,000 was expended in litigation prior to 1866.—EDITOR.]

In the beginning this contract proved most satisfactory to both parties. The Saturne company became very prosperous, paid back its loan with interest, and became the largest producer in the Bensberg district.

At the end of five years, however, it became evident that there was a growing increase year by year in the open-market value of zinc ores, which accrued to the Corphalie company to the detriment of the Saturne. This discrepancy between the open-market value and the contract price increased so rapidly that all sorts of negotiations were attempted on the part of the producer to mitigate the losses. Finally, about ten years after the signing of the contract, the Saturne company notified the Corphalie that thence forward they would cease to produce or market any zinc ore falling within the schedules of the contract and that they would sell ore only having less than 28% zinc, or enriched over 53%, and that if Corphalie people desired this class of ore, they would have to bid for it in open market.

The lawsuits resulting from this action were international in character, being carried on both in Belgium and Germany, as the Saturne company was a French corporation with a branch in Belgium. As years went on, intense personal bitterness between the presidents and managers of the two companies was developed and every endeavor at compromise was thereby rendered impossible. In 1868, when I became connected with the matter, everything had reached a deadlock. I had just completed the construction of a small zinc smelter for the Corphalie company at Ivanec, in Croatia, and on my return to headquarters my thorough knowledge of the language caused me to be put in charge of their ore-purchasing in Germany, and so the Saturne imbroglio was handed over to me. This necessitated my studying the old contract; I found among other things a clause in the contract giving Corphalie the right of appointing an engineer who at all times should have free access to the mines and works, laboratories, and books of record and accounts of the Saturne company, and providing that all underground and surface work should be submitted to him for approval. I called the attention of our president to this clause, and asked him whether he had ever taken advantage of it. He laughed and said that was a clause put in all such contracts, but that it could never be enforced. When I differed respectfully from him on this point, he asked me whether I would dare carry out the duties of such a position if the board should appoint me; I replied in the affirmative, provided I was given full power-of-attorney from our company, and that instructions were given to our counsel at Cologne to obtain what protection the Courts would give me under the contract. Within a week I was duly

appointed by our board and commenced one of the most exciting pieces of work any engineer ever undertook.

A formal notice having been served on the Saturne company that we proposed to avail ourselves of the clause in our contract giving us the right of inspection, I duly presented myself at their mine-office and presented my credentials. As I had expected, admission was promptly denied me. I then applied to the Court in Cologne for an order restraining the Saturne company from interference in my work of inspection, under the contract, and after a bitterly contested fight the decision was given in my favor. As there had been threats of personal violence if I persisted in my purpose of constant inspection, I further obtained from the Court the protection of an officer during my visits.

My first objective was a thorough inspection of the mine, so as to determine the actual condition, in extent and composition of the orebodies, and to find out whether for purposes of easier concentration they were leaving portions of orebodies unstoped, which economically ought to have been mined with the rest.

This investigation resulting in finding nothing objectionable in their methods of mining, I turned my attention to the surface operations. Here I found that they were actively engaged in re-modeling their ore-dressing plant, putting in improved grinding machinery and replacing the old straight buddles (*liegende heerde*) by the newly invented Rittinger tables, and the old Cornish buddles by modern revolving tables. After a few days' study of the general scheme of concentrating they had adopted I determined that the only way I could reach any decision as to what was going on, was to thoroughly sample each stage of the operations. I notified them of my intention, and was surprised that they raised no objection. I therefore brought in two assistants, and proceeded to sample the ore coming into the mill. That evening we took our samples home, for shipment to our own laboratory. Early next morning, I was arrested for stealing ore and taken to Cologne for trial. Our counsel had warned me before that they would probably take such action and so bail was ready when I reached Cologne. The case was pushed as quickly as possible, but before it came to trial I had been arrested 14 times on similar charges. The decision of the Court was that as I was acting under an order from the Supreme Court giving me the right of investigation, the taking of samples was a necessary part of my duties and did not constitute larceny.

Assured now of my legal status, I began an aggressive campaign in earnest. I sampled every ton of material coming out of the mill for shipment, and soon became expert enough to tell by sight within one or two per cent the zinc contents of any of their concentrates. The moment I saw a shipment being made of stuff that I felt sure did not exceed 53%, I had that shipment seized and held by the Court until the exact contents could be determined. Several times I fell down in my contention, and had to pay heavy damages, but it was really remarkable how few mistakes of this kind I made after I got accustomed to the appearance of the different grades of concentrate.

The Saturne company's engineers meanwhile were not sleeping, and a more perfect system of sampling and inspection of products from each of the concentrating machines was inaugurated, and every batch of concentrate that did not reach the desired point of concentration was returned to be re-treated. I have known of batches of several car-loads to go through the mill three times in order to raise the zinc contents above 53%, and yet the bulk of it had to be turned over to our company at last.

I don't suppose there ever was a closer study made of just what enrichment could be accomplished by each concentrating machine. Of course, the amount of so-called 'middling' that was produced kept on growing so rapidly under this system that additional crushing machinery had to be installed to take care of it. For 11 months, I never let up one moment in my work, and both the general manager of the Saturne company and myself were worn to a frazzle. It was found that the increased cost of operations due to this fight had been so enormous that for the first time in over 20 years they had not earned their dividend and this called the shareholders' attention to the situation, and caused dissatisfaction. During this prolonged fight, the manager of the Saturne and myself had got to know one another pretty well, and we finally put our heads together and evolved a scheme of compromise, which we succeeded in getting adopted by both companies. They paid us a round sum, not much less than the original loan, in return for the cancellation of the contract, and gave us preference at even prices in the sale of all their products. For my part, I received a formal vote of thanks from the board of our company accompanied with a present of a year's salary.

I consider that the experience gained during that year has been of extreme utility to me in my subsequent career. It taught me the necessity for close attention to the minutest details of any work undertaken, and it also taught me the advantage of mutual concessions in cases of dispute rather than fighting to the bitter end.

In the autumn of 1870 I was called into consultation by the Lehigh Zinc Co. to work out a method of concentrating their low-grade ores. The large surface deposits of calamine (zinc carbonate) ore, which had been the mainstay of their operations, were reaching a point of exhaustion, and in depth a gradual replacement of zinc sulphide was taking place.

This zinc sulphide, so far as I know, was unique in its physical character and was locally known as 'wax blende.' It was a mineral of rather dark greenish hue, non-crystalline, it had a decidedly conchoidal fracture, and in places was difficult to distinguish from the limestone in which it lay; it contained from 64 to 66% zinc, the only other impurity being a trace of iron.

The development of the zinc industry in this country at that time was still very much in its infancy; owing to the richness of the surface ores but little concentration had been necessary.

While engaged in this work I became acquainted with the two men who were the real pioneers in what may be considered the purely American process for the manufacture of zinc oxide direct from the ore, in contradistinction to the European method, where the oxide was produced from the metal. These men were Samuel P. Wetherill, of Philadelphia, and Nathan Bartlett, of Newark, New Jersey. While both of these men claimed the sole invention of the process, the result of the subsequent law-suits to determine priority resulted in awarding the furnace rights to Col. Wetherill, while the method of collecting the oxide fumes in bags, known as the bag-house system, was, I believe, proved to have been the invention of Nathan Bartlett.

During my stay in Bethlehem at that time I began also my life-long friendship with John Fritz, who was the manager of the Bethlehem Iron Co., now the Bethlehem Steel Co. Fritz, under the guidance of Alexander Holley and Robert W. Hunt, was struggling with the introduction of the Bessemer process, and I did a good deal of the analytical work for him. I remember his coming to me one day to ask me whether I did not think a point had been reached where it would pay the company to install a laboratory of their own, and I strongly advised him to do so. Some months later he wrote me that he had followed my advice and would like to show me what a fine laboratory he had established. On my next visit, expressing a desire to see this laboratory, he took me over to the works and, rather to my astonishment, led me to a loft over the company's stable, where his laboratory had been installed, that having been the only available room he had for the purpose at the time. When we compare the present laboratory facilities of the Bethlehem Steel Co. with this first venture of only 45 years ago, it certainly offers a wonderful contrast, though perhaps not more so than the comparison of the works as they now are with their aspect at that date.

The concentration of the carbonate zinc ores at Friedensville, near Bethlehem, having proved successful, I was called upon to install a plant to treat somewhat similar ores at the Sterling Hill deposits of the Passaic Zinc Co., at Franklin Furnace, New Jersey, and thus began my connection with one of the most remarkable mining law-suits that has ever been waged.

The suit in one shape or another lasted over 40 years, and my connection with it, off and on, extended some 12 years. The trouble originally arose from ignorance of the constituent minerals in the enormous outcrops at Mine Hill and Sterling Hill. At Sterling Hill the outcrop was principally red oxide of zinc mixed with a certain amount of franklinite, while the deposit at Mine Hill was apparently franklinite, only with a very small admixture of red oxide. Originally the franklinite was supposed to be a non-magnetic iron ore, and when treated in the blast-furnace had been found to produce an intensely hard pig-iron, due to the high percentage of manganese contained in the ore. This franklinite iron obtained a great reputation in those days for the manufacture of burglar-proof safes.

The original owner of the mining claims covering this deposit formed two companies, selling to each one of them a different grade of ore. To the New Jersey Zinc Co. he sold all the zinc ore on the property, while to the Franklin Iron Co. he sold all of the franklinite ore. For a while there was no question as to what was zinc ore or what was franklinite, because in those days it was supposed that the red oxide of zinc was the only zinc mineral present; later, however, when the big black outcrop in what was known as the Buckwheat Field opening was proved to be, not pure franklinite, but in reality a mixture of willemite and franklinite, the property, which was owned by the Franklin Iron Co., was claimed by the New Jersey Zinc Co. as coming under the specifications of their purchase of the zinc ores.

At the time the deeds were signed—if I remember right, somewhere about the year 1854—franklinite was an entirely new mineral, and it was not supposed that the small percentage of zinc that it contained was really a constituent of the mineral itself, which had therefore been generally classed as an iron ore. Later, after the suit was begun, the New Jersey Zinc Co. proceeded to establish the fact that franklinite was a definite mineral that could not contain more than 21% of zinc, and that therefore all minerals in the deposit containing more zinc than that amount must necessarily fall under the classification of their deed.

On the other hand, the Moses Taylor Iron Co., successors of the original Franklin company, maintained that what had been deeded to them was all the dark-colored ore which had generally been known in those days as franklinite, notwithstanding the fact that later on this black color, which was due principally to surface oxidation of the manganese contents of the ore, disappeared in depth and showed the ore to be willemite.

It took a long time to enable the experts engaged on both sides to prove by actual demonstration that the constituent parts of the orebodies could be separated mechanically into ores commercially valuable for the metals contained in them. It was no difficult thing to separate the crystalline franklinite from the willemite or from the red oxide of zinc, but when in addition it became necessary to separate the manganese minerals, rhodonite and rhodochrosite, from the willemite and the franklinite the difficulties were very greatly increased.

Finally the litigants were brought together on a merger of their interests and the actual points at issue on the main suit were never determined legally. While this compromise resulted in the formation of the present New Jersey Zinc Co., the largest corporation of its kind in the world, it was a good deal of a blow to the legal fraternity and to the experts engaged on both sides, to whom it looked as though they had lost their birthright. It was not till many years later that the economical concentration of these zinc ores was finally made successful by J. P. Wetherill's invention of his system of 'paramagnetic' separation, the development of which has been one of the chief factors in the commercial success of the New Jersey Zinc Company.

The Rochester Mill, Nevada

By G. W. WOOD

The Rochester mill, which was designed by the writer as engineer for the Dorr Cyanide Machinery Co. and started on March 30, 1915, by him, as consulting engineer for the Rochester Mines Co., with C. W. Poole as superintendent in charge of the mine and mill, is probably of general interest from a metallurgical standpoint as a typical installation of a continuous counter-current decantation cyanide plant, operating on silver ore, using Dorr thickeners exclusively without a filter, and embodying throughout a number of details perfected in the operation of older plants that may be regarded as the best previous practice in a plant of this type.

The mill is treating custom ores and for this reason no definite information can be given regarding the extraction now being made other than that the recovery is as complete as is possible in treating an ore of a particular character and that the loss in dissolved value is less than that originally estimated.

Herewith I give the theoretical solution flow-sheet, based on a capacity of 100 tons of ore per day. It follows the lines on which the mill was designed, and with results in actual milling that have conformed closely with expectations. The plant to date, however, has developed a daily capacity of about 120 tons. To simplify the description the capacity is assumed as 100 per day, namely, the tonnage that the mill was originally designed to treat.

All figures refer to solution tonnages.

Calculations for Loss in Dissolved Silver and Gold

Conditions assumed:

(*a*) 100 tons of ore per day crushed in cyanide solution.
(*b*) Discharge from all thickeners with 44.4% moisture.
(*c*) $14 value dissolved per ton of ore.
(*d*) 35% in mill; 55% in first two agitators; 10% in last agitator.
(*e*) 600 tons of solution from thickener U precipitated to 2 cents.
(*f*) Agitation with a dilution of 2 parts of solution to 1 of solid.
(*g*) Let U, V, W, X, Y, and Z represent value in dollars per ton of solution discharged from the respective thickeners.

Equating out of and into each thickener:

(1) $600\ U + 80\ U = 680\ V + (100 \times \$14 \times 0.35)$.
(2) $800\ V + 80\ V = 680\ W + 80\ U + 120\ V + (100 \times \$14 \times 0.55)$.
(3) $680\ W + 80\ W = 80\ V + 480\ X + (100 \times \$14 \times 0.10) + (200 \times 0.02)$.
(4) $480\ X + 80\ X = 80\ W + 80\ Y + (400 \times 0.02)$.
(5) $80\ Y + 80\ Y = 80\ X + 80\ Z$.
(6) $80\ Z + 80\ Z = 80\ Y + (80 \times \$0.00)$.

Simplifying:

(1) $680\ U = 680\ V + 490$
$U = V + 0.7206$
(2) $880\ V = 680\ W + 80\ U + 120\ V + 770$
$V = W + 1.2172$
(3) $760\ W = 80\ V + 480\ X + 144$
$W = 0.7059\ X + 0.3545$
(4) $560\ X = 80\ W + 80\ Y + 8$
$X = 0.1589\ Y + 0.0722$
(5) $160\ Y = 80\ X + 80\ Z$
$Y = 0.5431\ Z + 0.0392$
(6) $160\ Z = 80\ Y$
$Z = 0.5\ Y$

Solving:

(1) $U = 2.3491$
(2) $V = 1.6285$
(3) $W = 0.4114$
(4) $X = 0.0807$
(5) $Y = 0.0538$
(6) $Z = 0.0269$

To check these figures:

The amount precipitated from 600 tons, at $2.3491 — 0.02	$1,397.46
The amount lost in tailing, 80 tons at $0.0269	2.15
	$1,399.61
The amount due to neglected decimals	0.39
	$1,400.00
The amount dissolved, 100 tons at $14	$1,400.00

Calculation for Mechanical Loss of Cyanide

Conditions assumed:

(*a*) Neglect the cyanide consumption throughout the system.
(*b*) Strength of cyanide per ton of solution, 4 pounds.
(*c*) Let U, V, W, X, Y, and Z represent the strength in pounds of cyanide in solution discharged from the respective thickeners.

Equating out of and into each thickener:

(1) $U = 4$
(2) $800\ V + 80\ V = 680\ W + 80\ U + 120\ V$
(3) $680\ W + 80\ W = 480\ X + 80\ V + (200 \times 4)$
(4) $480\ X + 80\ X = 80\ W + 80\ Y + (400 \times 4)$
(5) $80\ Y + 80\ Y = 80\ X + 80\ Z$
(6) $80\ Z + 80\ Z = 80\ Y + 80$ tons of water.

Simplifying:	Solving:
(1) $U = 4$	$U = 4$
(2) $V = 0.8947\ W + 0.4021$	$V = 3.8311$
(3) $W = 0.6973\ X + 1.2088$	$W = 3.8326$
(4) $X = 0.1586\ Y + 3.365$	$X = 3.7628$
(5) $Y = 0.5430\ Z + 1.8274$	$Y = 2.5084$
(6) $Z = 0.5\ Y$	$Z = 1.2542$

$\frac{80\ Z}{100} = 1.0033 =$ mechanical loss of cyanide per ton of ore.

The operation of the mill is as follows: As originally outlined, the ore from the Rochester mine, or from the various 'leasers' shipping to this mill, is delivered from cars of the Nevada Short Line to five 60-ton bins. From these bins it is trammed to the mill in a car of 1½ tons capacity, weighed on a recording-beam scale, and then dumped over a grizzly (1½-in. opening) to a 20 by 10-in.

Blake crusher. The fine from this grizzly goes direct through a fine-ore chute to the boot of a No. 4 Gates bucket-elevator, the oversize passing through the crusher and then dropping into the same chute with the fine from the grizzly to the elevator-boot. From this point the ore is elevated to the top of the sampler. The elevator used in this installation conforms to the original design of the manufacturer, except that malleable-iron buckets were substituted for the standard bucket.

The ore, after being elevated, drops by gravity to a No. 3 single Vezin sampler, which takes out one-tenth. The reject of 90 tons from this sampler falls through a chute direct to the crushed-ore bin, while the cut, or sample of 10 tons, drops to a shaking feeder that retards and distributes it, and thus makes it feed continuously to a 7 by 9-in. Dodge crusher, in order to insure perfect sampling later. After passing through this crusher the sample is again cut by dropping through a No. 2 single Vezin sampler, which takes out one-tenth from the original sample, the reject of 9 tons dropping to the crushed-ore bin, the sample of 1 ton dropping to a second distributing shaking-feeder. This second feeder uniformly feeds the cut or sample to a set of 12 by 12-in. rolls for further crushing. The sample as it drops from these rolls is again cut by passing through a No. 1 single Vezin sampler, which takes the final one-tenth sample. The reject, nine-tenths of a ton, drops to the boot of a 6-in. elevator, which drops it into the crushed-ore bin, and the sample of one-tenth of a ton, or 200 lb., falls into a locked box in the sample-room.

After the lot of ore has been crushed and sampled, the sample is transferred in the presence of a representative of the owner of the ore to an Engelbach crusher, which again grinds it. From this crusher it passes over a series of five riffles, which cut out two separate uniform samples (one for the customer and one for the mill) for moisture and assay, the waste or reject after the sample has been cut-down being put into the boot of the 6-in. elevator, which lifts it into the crushed-ore bin.

The ore, having been crushed and sampled, is then fed by gravity to two suspended tappet-driven feeders, which deliver it to two batteries of five 1550-lb. stamps, each, dropping 100 times per minute. These batteries are fitted throughout with chrome-steel parts and each is driven by a 20-hp. back-geared Bullock motor, with special controller by means of which it is possible to start each battery without recourse to hanging the stems on fingers. The shoes are fastened with hard-pine wedges and no trouble whatever has been experieneed thus far from shoes dropping off.

The ore, which up to this point has been dry, is mixed with cyanide solution as it drops into the batteries, and remains in solution from now on throughout the process for the dissolution and extraction of its gold and silver content, and the dilution of the various strengths of solution with which it comes in contact, until it passes out of the mill as tailing. All flows or transfers of pulp and solution now mentioned throughout the process are continuous and the tonnages given in each case are for 24 hours. The solution added at the batteries is 680 tons daily of the standard mill-solution, which is the clear overflow from No. 2 thickener.

From the batteries, the ore mixed with the solution, or 'pulp,' as it will now be called, flows by gravity through a launder to the feed-trough of a duplex Dorr classifier, made special in size for this mill. This classifier is installed in closed circuit with two 5 by 16-ft. tube-mills. Pulp that is *minus* 200-mesh or finer flows over the discharge end of this classifier to thickener No. 1. The coarse sand that would remain on a 200-mesh screen is carried over the other end of the classifier and drops over an inclined plate to a right- and left-hand screw-conveyor, which feeds it with 33% moisture to the feed-scoops of both tube-mills, or, in case of necessity, all of the pulp may be fed to either tube-mill independently.

The tube-mills are of the trunnion type and fitted with Komata hard-iron liners with manganese-steel ribs. They were adopted for use in this mill after a careful investigation of the various types of liners in use in other plants with authentic information on direct results obtained in each instance over long periods of time. Both tube-mills are driven by a single 100-hp. special-torque Bullock motor, connected to the tube-mill pinion-shafts by Morse silent-chain drives with spring hubs and cut-off couplings.

The pulp discharged from the tube-mills flows by gravity through a launder back again to the feed-trough of the classifier, where further classification of the –200 material is made. The oversize is returned again to the tube-mills for further grinding, and the –200 pulp that has come from the tube-mills mixes with the –200 pulp from the batteries, flows over the slime-discharge end of the classifier through a launder directly to thickener No. 1. The clear overflow from thickener No. 1, which is 600 tons of the solution coming from the classifier per 24 hours, flows into a clarifying-tank and is pumped as pregnant solution to the zinc-boxes, where the silver is precipitated on zinc shaving. Perfect precipitation has been maintained in these zinc-boxes with a barren-solution overflow since the mill started. The clarifying-tank is used merely for precautionary reasons to insure an absolutely clear solution at all times. Sizing tests made on the slime-discharge from the classifier have averaged 94% of *minus* 200-mesh.

From the original laboratory-tests made on the ore, to allow for any possible variation that might occur in actual milling, and in order to have an ample margin of safety, discharges from the various thickeners were calculated with 44.4% moisture. This is the basis used in this description, although subsequent operation in the mill has reduced this percentage of moisture, with corresponding benefit to the general results.

In thickener No. 1 the pulp is settled. The settled pulp, or underflow, from this thickener is pumped continuously through a pipe connecting the discharge-cone of the thickener with an eccentric-driven diaphragm-pump, which elevates it and discharges it into agitator No. 1. Additional mill-solution, or 120 tons daily of the

clear-solution overflow from thickener No. 2, is added to this pulp as it goes into the agitator, in order to dilute to 2 of solution and 1 of solids. This pulp, thus diluted, overflows continuously to agitator No. 2, receiving a total of 48 hours continuous agitation in these two agitators while flowing through them.

From the second agitator the pulp flows to thickener No. 2, where as it goes through the launder to the loading-well it is further diluted and mixed continuously with 680 tons of the clear-solution overflow from thickener No. 3.

In thickener No. 2 the pulp is again settled and pumped from the discharge-cone into agitator No. 3. Here it is diluted by the addition continuously of 200 tons daily of barren solution from the zinc-boxes; it is given 24 hours' continuous agitation with this charge of solution and simultaneously therewith is discharged continuously to thickener No. 3, where, as it flows to the loading-well, it is diluted and mixed with 480 tons of clear overflow from thickener No. 4. From thickener No. 3 it is pumped over into thickener No. 4 and is diluted as it flows into same with 80 tons of clear overflow from thickener No. 5, together with 400 tons of barren solution from the zinc-boxes. From thickener No. 4 the settled pulp is pumped over into thickener No. 5 and diluted with 80 tons of clear solution from thickener No. 6. From thickener No. 5 it is pumped into thickener No. 6 and diluted with 80 tons of water. From thickener No. 6 the settled pulp is pumped as tailing; the aim at this point being to maintain the discharge at a uniform moisture.

The essential mechanical feature of the process is that all solutions flowing into and out of the respective thickeners must balance each other. This may seem a little complicated, but the manner of doing it has been carefully studied in the various plants already in operation, so that with a few minor adjustments that are necessary in starting a plant, and that are easily made, the mill soon becomes practically automatic.

The pumping of pulp in the mill from and to the various thickeners is done with diaphragm-pumps throughout. These I believe preferable to the other method of handling the pulp with air-lifts, as the action of the diaphragm-pumps is more positive. This type of pump requires little attention, its wearing parts are easily and cheaply replaced, and any likelihood of trouble is reduced to a minimum. In starting the plant the capacity of the pumps is first regulated from the length of stroke by means of adjustable double eccentrics capable of giving any length of stroke desired. Slight changes in this original adjustment are made by means of a pet-cock on a small pipe attached to the pipe leading to the suction end of the pump, so as to allow air to enter at this point as desired and thus cut down the capacity of the pump to any required amount.

The tailing is now sampled at half-hour intervals by hand, and the sample collected in each 24-hour period is mixed thoroughly, cut-down, and a washed sample assayed for undissolved loss; while loss in solution is determined by assaying the filtered solution and calculating from it the dissolved loss per ton of solid. With the uniform discharge given by the diaphragm-pump it has been found that sampling such a thick pulp at regular intervals gives reliable results.

In the Rochester mill the successive thickeners are stepped up, which method appears preferable to that of having all the thickeners on the same level, as it permits of the clear overflow solution returning directly by gravity to the respective thickeners preceding them; it eliminates the necessity for air-lifts to transfer these solutions as in the other method; at the same time it sim-

FLOW-SHEET OF MILL.

plifies the operation of the plant in other ways and generally speaking makes the transfer of pulp and solution more nearly fool-proof.

The complete equipment for the mill, including that made by the Dorr Cyanide Machinery Co., was furnished by the Allis-Chalmers Manufacturing Co. I wish to express my appreciation of their work in connection with this installation and also that of C. W. Poole as directly instrumental in the success of the plant.

Treatment at the Big Pine, Manhattan

By P. J. QUINN*

†The gold-bearing rock at the Big Pine mine, at Manhattan, Nevada, is a soft schist. The mine is worked by the glory-hole method, the ore dropping into chutes at the 200-ft. level, trammed to the shaft and hoisted to the surface. The gold is free, and, there being no sulphides, it is saved by amalgamation only.

In December 1913, Messrs. Mushett and Wittenberg purchased the Brady mill, consisting of 10 stamps and a 4½ by 16-ft. tube-mill, with two battery-plates and three tube-mill plates, and a cyanide-plant, which was not used on Big Pine ore. For several months, the ore, as broken in the mine, was sent to the mill for treatment. Later, however, it was found more advantageous to crush and screen the ore at the mine, and reduce only the fine material that passed an inch-square opening.

As soon as we began to mill the finer product, Mr. Mushett decided to experiment and see if all grinding could be done in the tube-mill. So the ore was sent from the battery-bins direct to the tube-mill. As a result of these tests the mill to be described was built at the mine and began operating in December 1914:

The ore is crushed in a 10 by 16-in. Blake crusher made by the Joshua Hendy Iron Works of San Francisco, elevated, and passed over an inclined-screen having 1-in. square openings. The oversize is considered waste. The fine ore drops to the mill-ore bin, and is fed to a 5 by 20-ft. Allis-Chalmers tube-mill, working at 28 r.p.m. Attached to the discharge-end of the mill is a trommel made of 6-mesh screen. The material that passes through this screen—more than 99% of the pulp—is distributed over three silver-plated amalgamating-plates. These are 12 ft. long; two of them are 4 ft. 9½ in. wide, and one is 4 ft. 6 in. wide. They have a grade of 1¾ in. per foot. At the bottom of each plate is a trap through which the pulp passes to a Frenier pump. The pulp is elevated to a Dorr simplex-classifier, the coarse going back to the tube-mill. The overflow from the classifier passes over blankets 44 in. wide and 8 ft. long, thence to the tailing-pond. Between 85 and 90% of this residue will pass 200-mesh and it averages 40c. per ton.

No amalgamation is done in the mill; on the contrary, the aim is to keep all amalgam and quicksilver from getting into it. To prevent this, cleats are placed in the launder at the end of each plate, and riffles are fitted in the launder leading from the traps to the Frenier pump. The consumption of quicksilver is very small.

The pebbles used are a local product, known as the Maris. The consumption is 2½ lb. per ton of ore. During March, April, May, and the first 17 days of June, we have ground 11,000 tons of ore, the mill operating 76% of the time.

Space is left between the feeder and the tube-mill for some primary grinder, in case it may be found necessary to install one. Since the crusher is not large enough to produce sufficient ore to insure steady running, a Gates type, K machine, No. 5, is being installed; also a trommel. When these are in operation the mill will have to grind material up to about ⅝ of an inch.

*Superintendent of the Big Pine mill.

†Abstract from *The Tonopah Miner*.

MEDANOS, or crescentic sand-dunes, reach their perfection between Mollendo and Arequipa, Peru. Gazing from his car-window on a plain covered with small pebbles, bare, barren, and wind-swept, the traveler from Mollendo first sees a wagon-load of sand lying by itself. The little heap of sand—a *medano*—is so isolated that his first thought is that some one is going to build a house or is sinking a shaft. Soon other and larger piles of sand are seen—all with clean-swept rocky floors between them. Within a few miles the *medanos* increase in size and number until the whole plain is covered with them. The largest is about 150 ft. long and 30 high; they are beautifully smooth perfect crescents with sharp horns, lying with their convex side toward the sea, from whence they came, and toward the wind. Sixty miles away from the sea, they are still moving onward. In their stately array they seem a vast army; like an army they advance, preserving their regular form as long as they stay on the plain. On climbing a hill they lose their shape and become mere mounds of sand; once over the summit they adjust themselves and again assume a crescentic shape, but hardly as perfect as their original form. Finally, after crossing several hills and valleys they merge in long low dunes. In their progress they cross the railway. Much labor is necessary to keep the tracks clear. In a year they travel perhaps 50 feet. A thin coating of loam stops their progress. They are the result of a wind that blows steadily and gently from the sea for months at a time. Standing near them one can see that a little sand is being blown from the windward side over the crest, whence it falls into the concave side of the crescent. Thus the *medano* is constantly turning and progressing by a sort of rolling motion. Nicely balanced are the forces that produce these beautiful forms. With the wind a little stronger, or blowing less steadily, they would be shapeless dunes that guard so many sea-coasts. A gentler wind would not form them. Travelers who have seen much of the world find these *medanos* the most extraordinary of all physiographic phenomena. A moving picture of these migratory dunes would be of great interest, but as not much motion would be shown in less than 500 years, we are not likely to see it. The *barkans* of Turkestan are said to be crescentic in form, but it is doubtful if they are as perfect as the *medanos*.

The Water-Supply for the Klondike Hydraulic Mines

By H. H. HALL†

*While the earlier discoveries in the Klondike region were along the creeks where a water-supply was easily made available, it was soon found that much ground at a considerable height above the streams contained enough gold to make hydraulic mining a profitable venture. To provide a water-supply, the Yukon Gold Company con-

EXCAVATING DITCH WITH TEAMS.

structed the works hereinafter described. The project involved the construction of seventy miles of conduit from the Ogilvie range of mountains southwesterly to the Klondike mines near Dawson City, for the purpose of conveying 125 second-feet of water, or about 80,000,000

EXCAVATING DITCH WITH STEAM-SHOVEL.

gal. per day. The region traversed lies behind the great Alaskan range of mountains, which are nearly 20,000 ft. high, and cut it off both from the warm, moist air of the Japan current and also from the severe wind storms common along the Alaskan coast. The temperature ranges from 43° to 68° below zero in January to 60° to 95° above zero in July. The country is a low, rolling plateau cut by minor mountain ranges seldom exceeding 7000 ft. in height. It abounds in spruce timber growing as large as two feet in diameter in the river bottoms, but on an average four inches in diameter and 20 ft. high. The top layer of ground is frozen mud, or 'muck,' composed of decayed vegetal matter, frozen as deposited and varying in depth from nothing to several hundred feet. This is overlain by a blanket of moss often a foot or more in thickness, which has the effect of preserving the muck in a frozen condition throughout the year. The chief economic assets of the country are gold and coal, but on the southern slopes, whenever the timber and moss have been burned off, the ground thaws rapidly, and grasses, vegetables, and wild berries grow profusely.

The conduit comprised 21 miles of flume, 37 miles of open ditch, and 12 miles of pipe, constructed under separate organizations during three seasons of about 120 days each, from 1907 to 1909.

Ditch construction was used wherever possible. The

NATIVE TIMBER USED DURING CONSTRUCTION.

ditch was made seven feet wide on bottom and 3½ ft. deep with 1½ :1 slopes. The gradient ranged from four to seven feet to the mile, the greater portion being six feet. The ditch was carefully placed so as to bring the entire working-area in cut. The right-of-way was first cleared of trees, and the muck scraped off with teams and slip-scrapers as fast as it thawed. The latter work presented the most troublesome problem from a construction standpoint owing to the uneven thawing of the muck and the consequent miring of the horses. In some cases, upon the removal of two or three feet of muck from a slope of mixed clay, gravel and ice, the thawing of the upper bank thus exposed started a small slide. This would break the moss above the ditch and allow more thawing, until a strip as much as 200 ft. wide and a quarter of a mile long would start to slide slowly down on the right-

*Abstract of paper read before the San Francisco Association of Members of the American Society of Civil Engineers, April 16, 1915.

†Civil Engineer, 200 Bush street, San Francisco.

of-way, carrying trees and vegetation with it. No preventive was discovered for this.

Thirty miles of ditch was dug with six 30-ton steam shovels, the remainder with horse-scrapers. As the shovels required a working-space at least 16 ft. wide, no side-sloping was done with them. Small quantities of frozen material were removed with 40% dynamite but the larger patches were passed over, and after thawing were taken out with scrapers. The shovels worked two 10-hour shifts and burned about three cords of wood per day. The record performance for one shift was 410 lin. ft. of ditch, or 1200 cu. yd. and the average performance was 14.7 lin. ft. or 51 cu. yd. per working hour, or 11.2 lin. ft. or 38.7 cu. yd. per available hour. The season lasted from June 15 to about October 15, with work usually slow the first and last weeks, 100 working days being about the true season-length. The teams and scrapers accomplished from 8 to 20 yd. per horse-day, averaging about 15 yd.

4 Ft. x 6 Ft. FLUME COST EXPRESSED IN MAN DAYS, (10 HOURS.) PER LINEAL FOOT OF FLUME.

Flume Construction.	.145	
Superintendance.	.014	
Total.	.847	

General Expense amounted to about 4% of total cost.

TABLE OF FLUME COSTS.

While the actual cost per lin. ft. of ditch was about the same for shovel-work as for scraper-work, it should be remembered that the number of horses in the region was limited. To attempt to construct the entire ditch with horses would have either delayed the completion of the project or else compelled the importation of a large number of animals. The latter course would have added greatly to the cost of the work. The use of steam-shovels was therefore a much greater saving than would appear at first sight from the cost-summary.

The finishing gang followed the shovels, truing the grade, sloping the banks, clearing the berms, building a path along the top of the spoil bank for watchmen, and constructing turnouts and overflows alternately every half-mile. In porous ground, the shovel gang endeavored to keep below grade and the finishing gang filled in the depressions with six inches of moss and a covering of top soil. In soluble materials a trench was dug against the lower bank, extending two feet below grade, and a layer of sheet piling placed over the side of the ditch with a single tie at the top, this piling then being covered with moss and top soil. The average labor cost of finishing per lin. ft. was 0.094 of a man-day plus 0.018 of a horse-day. Common labor was paid $4 per day and board, and horses were hired at $100 per month, including found. Under operation the ditch has proved satisfactory, leaks

being usually caused by ice seams. These breaks cannot be re-filled, and where they occur, flume construction has to be substituted. Caving banks were protected by brush laid lengthwise with tops up-stream, held in place by stakes.

Where the side-slopes exceeded 15° or the muck was over 2 ft. thick, flume construction was adopted of board-and-batten type and was 6 by 4 ft. The flume was built of native lumber, made up in 16-ft. sections and set on

WEAK POINT IN DITCH, LINED WITH TIMBER.

trestle-bents of hewn timber 8 ft. centre to centre. Most of the bents were carried on mudsills laid below the black muck, or about four feet deep, great care being taken not to disturb the moss-blanket unnecessarily and to replace it as quickly as possible over the back-filling in order to preserve the ground in a frozen condition. Even at that

HYDRAULIC MINE.

the ground thawed so rapidly that the workmen were forced to work in mud and water. The cost of excavation was sometimes as great as $5 per cubic yard. Winter-work was tried, but the snow rendered it uneconomical. The bents cost nearly $20 apiece in place. An attempt was made to space the bents 16 ft. centre to centre, but this was found to be impracticable on account of the softness of the foundation.

The experiment was tried of supporting some of the bents on piles driven into earth that had previously been thawed out by means of 16-ft. miner's steam-points. In this manner the moss was broken only to admit the pile, and if allowed to stand a winter before water was turned in, the ground around the pile froze and returned to its original state. Where the depth of muck would require deep mudsill-pits, gravel ballast was placed directly on top of the moss and the flume-stringers were laid on ties as are the rails in railroad construction. The labor cost in man-days of 10 hours per lineal foot of flume were as follows: hauling flume lumber, 0.159; getting out timber for bents, 0.105; surveying, 0.025; clearing out trees, 0.025; excavating, 0.139; bent construction, 0.094; backfilling, 0.016; flume construction, 0.145; miscellaneous, 0.125; superintendence, 0.014; total, 0.847. Operation of the flumes for several years has shown that the pile-foundation is the best, the mudsill-bents showing continual settlement, caused by water flowing down the posts, either from the flume or from natural drainage, and thawing the sub-strata.

Pipe lines were employed for pressure sections. Their construction has been described by W. W. Edwards, in Proceedings of the American Society of Civil Engineers for May, 1914. For pressures not exceeding 200 ft., redwood stave-pipe was used; for pressures over 200 ft. and less than 1000 ft., standard riveted pipe; for pressures over 1000 ft., lap-welded steel pipe. One section was constructed of spiral-riveted pipe with patent bolted couplings.

Under operation it has been found that because of the lines being drained and closed from the first of October to the first of June of the following year, the wood pipe has given considerable trouble. This is particularly true where the pipe was left above ground, the staves drying out and shrinking, necessitating back-cinching practically the entire line before putting it in use each year. The water leaking between the dried-out staves tends to thaw the foundation, causing settlement and opening of joints. This makes a leak that is difficult to repair. As the pipe does not run full all the time, there is an accumulation of drift on the intake end. In spite of the use of grizzly-bars this has worn holes in the wood lines. Some staves have rotted. The sand and gravel carried by the ditch-water has worn the bottom staves badly and all intakes are now provided with sand-boxes. Accumulations of ice at the discharge ends have caused considerable trouble by increasing the pressure on portions of the pipe. The steel pipe has given little trouble, but on high-pressure lines the sediment cuts the steel rapidly and in one instance a ¾-in. rivet was cut away in two weeks.

ORE RESERVES at the Braden mine, Chile, are as follows: Fully developed 66,000,000, probable 20,000,000, possible 27,000,000; a total of 113,000,000 tons. Of this quantity there was in the Fortuna mine 17,000,000, in the Teniente 83,000,000 tons, and in the Regimiento 13,000,000, the grade being 2½% or better.

Cost of Constructing the Tonopah-Belmont Mill

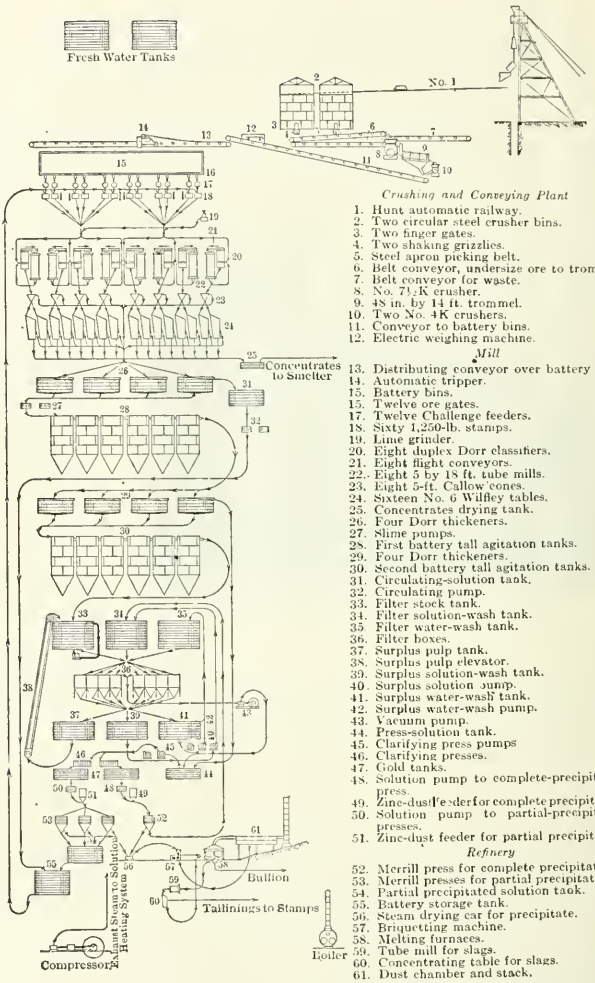
In Bulletin 104 of the A. I. M. E., this plant is described in detail by A. H. Jones, metallurgist for the Tonopah-Belmont Development Co. Although the mill started work in July 1912, it has never been fully described in any technical journal. Excavation commenced in August 1911, about one year being required for its construction under the supervision of Otto Wartenweiler. The accompanying flow-sheet and table show the process of treating the silver-gold ore, and cost of erection, respectively. The total cost of the plant, designed to treat 500 tons per day, was $465,189.07. The saving in operating costs and increased extraction, as compared with the best results from the old plant at Millers, 12 miles away, was such as to return the entire cost of the new plant from the treatment of 260,000 tons of ore, or approximately 18 months' operation.

The extraction from 438,708 tons, up to March 1, 1915, was 96.2% of the gold, 93.0% of the silver, and 93.9% of the money value.

The mill has concrete floors throughout. The grinding and concentrating floors drain to the lower Dorr thickeners, and the lower floors to a common sump from which solution-leaks and overflows can be pumped back into mill-circuit. The initial saving effected by not laying concrete floors is false economy, according to Mr. Jones, as the waste bound to occur in any cyanide-plant will soon exceed the cost of construction.

Everything is driven by electricity, 39 motors consume a monthly total average of 813.69 hp. Of this the crusher and trommel absorb 15.146; 60 stamps, 157.8; classifiers, 8.71; 8 tube-mills, 462.17; concentrators, 9.3; thickeners, 5; circulating pumps, 20.1; agitating pumps, etc., 16.069; filter pumps, 45.94; precipitating department, 33.63; assaying, 2.791; refining, 1.835; machine-shop, 5.36; and lighting, 12.45 hp. The horse-power per ton milled is 1.627.

The total cost of treatment during the financial year 1914-15, when this mill treated 181,424 tons of ore, assaying 22.3 oz. silver, and 0.2336 oz. gold, was $2.156 per ton. In July 1915, the plant treated 14,020 tons yielding 253,420 oz., and a profit of $72,459.



Crushing and Conveying Plant

The History of Gold Mining in the Philippines

*According to Chinese historians, Luzon was noted for gold as early as the third Century, when it was the chief article of export to China.

The regions that were most famous in antiquity are the leading mining districts of today. Morga, writing more than 300 years ago, spoke of the rich gold mines of northern Luzon as being guarded by the savages of the region in order that no Spaniards might learn their situation. Undoubtedly the mines in operation today in Benguet are in the region forbidden to the earliest Spanish explorers. Hernando Riquel made the following enthusiastic statement in his "very true and certain account of what has recently (1574) been known concerning the new islands of the west:"

"There are many mines of gold in many parts (of Luzon) which have been seen by the Spaniards, and all say that the natives work it as they work silver mines in New Spain (Mexico). And the metal has a continuous vein like silver ore. Trials have been made and the mineral presents itself so plentifully that I hesitate to write about it lest they should suspect me of exaggeration; but it is sufficient to say that I swear as a Christian that there is more gold in this island than there is iron in Biscay."

The placers at Paracale were undoubtedly worked before Spanish occupation, perhaps even more energetically than afterward. In 1578, according to official reports, the people of Mambulao and Paracale subsisted entirely upon the profits of mining, although they worked without intelligence and without industry. The Philippine production of gold in Morga's time (1609) was about $200,000 annually, apparently, and nearly all of this amount must have come from Paracale and Mambulao.

William Ashburner, a celebrated American mining engineer, examined properties in Surigao together with the lode-gold on the island of Panaon, about the year 1883. He learned that in Surigao the natives were taking out about $20,000 per year, but he was not induced to recommend the region to his principals.

One of the most romantic episodes in the history of Spanish mining in the Philippines is the career of the famous Ancla de Oro, a company which was established to exploit the Veta Real at Mambulao. This company planned to obtain access to the vein below ground-water level by constructing a sea-level drainage-adit. The prospectus describes the vein on the Benditas Animas, a claim that had been bought and sold as early as 1788. The vein was said to be "two palms" wide, the quartz of it being literally "bedizened" with gold until it "has the appearance of the richest altar hanging," and not only the vein but "the adjacent walls are also gold-bearing." The document ends with the following stirring appeal:

"To those who love their country the opportunity now presents itself to show that they interest themselves in her progress and welfare. One hundred pesos is the cost of a share, payable in four installments. Even if our hopes which are fundamentally so conservative should not be realized, the loss of one hundred pesos will bankrupt no one, so we have no doubt that all will take shares in the enterprise which is this day initiated.—Manila, March 19, 1848, Isidro Sainz de Baranda."

The Ancla de Oro failed ultimately after a long and aggressive effort to extract gold from the refractory ores. The well-preserved portal of their drainage-adit may still be seen and is usually the first evidence of mining to catch the eye of those who enter Mambulao Bay by steamship. The adit itself, however, is caved a short distance from the entrance.

The Spanish government appears to have done as much

*Abstract of a paper by Wallace E. Pratt in the Philippine Mining Bulletin of May 1915.

as it could to promote the gold-mining industry. As early as 1636 the privileges of miners in the Philippines were especially safeguarded by royal decree. Legal procedure for the alienation of mining titles was in effect at a very early date.

On July 1, 1902, the American Government enacted its own mining code for the Philippine Islands, providing for the recognition of all genuine Spanish grants. As a matter of fact only 113 Spanish concessions complied with the requirements for approval, and these are in effect under the new law.

The American mining law placed all public land, mineral, forest, or agricultural, in the hands of the Director of Lands, and the Mining Bureau was re-organized as the Division of Mines of the Bureau of Science. In the Division of Mines the Government now maintains—as the re-organization clause summarizes its purposes—a mining, mineralogical, and metallurgical museum and library open to the public at reasonable hours; in effect, a bureau of information concerning the mineral industries of the Philippine Islands.

The American prospector immediately followed the trail of his Spanish predecessor over the old workings of the native. It is a significant thing that with no important exception up to the present time all the discoveries of both Spanish and American miners have been made on the sites of former Filipino activity. Benguet and Camarines soon became American 'diggings;' a little later Masbate and Mindanao were invaded and although prospectors have touched on practically all the larger islands these four districts continue to be the leading gold-producing centres. Quartz mining in Benguet became established more promptly than the operations elsewhere, and in 1907, with three small stamp-mills operating, produced 3888 fine ounces of gold worth approximately 168,600 pesos. Two small mills had also been erected in Masbate. These first mills were designed essentially for the amalgamation process. It soon became apparent, however, that the ore required cyanidation and all the modern mills employ the cyanide method.

A small Risdon dredge started work on the Lanang river, Masbate, in 1905, but it was wrecked by a typhoon before the value of the ground was established. Another of similar type commenced operations about the same time on the Guinobatan river, in the same district, but did not recover enough gold to pay expenses.

The American prospectors in Camarines early recognized the greater accessibility of the placer-gold there as compared with the lode-gold, although the San Mauricio and Tumbaga lode-mines had come into the hands of Americans. A New Zealand dredge began operation on the Paracale river in 1906 and established the future of gold dredging in that district by winning 101,307.60 pesos from 50,244 cubic yards of material. In 1908 the Risdon dredge was brought from the Guinobatan river in Masbate to Paracale and after a period of experimental operation was placed on the Malaguit river, where, in spite of its small capacity, it continued profitable operation until the middle of 1914.

It is beyond the purpose of this sketch to review in detail the trials and difficulties through which American mining in the Philippines has grown to its present considerable proportions. Gold production, which had reached a value of 187,647 pesos in 1907, rose to nearly ₱500,000 in 1909, fell to barely ₱300,000 in 1910, and has reached ₱2,300,000 in 1914. Typhoons destroyed the Headwaters, Benguet Consolidated, and Bua mills in 1910, but the damage is being remedied and the new Benguet mill being re-built during the summer of 1915 should produce enough gold to enable the district to recover its former leading position.

The development of the Philippines mines, thus far, has been due to the prospector and the small capitalist. The mineral deposits of the Archipelago are widespread and a fair proportion of them are valuable. With capital wisely directed by skilled mining engineers there is every prospect for the development of a profitable industry.

Monazite

According to the Bureau of Mines, there exists a possibility that this country's resources of monazite can be used profitably in the manufacture of the chemical products, thorium and mesothorium. Thorium nitrate is used extensively in the manufacture of incandescent gas mantles; mesothorium has been successfully employed in therapeutics, its properties being similar to those of radium. Most of the monazite imported in late years has come from Brazil, where the mineral occurs in the beach sands along the coast and where it could be mined more cheaply than from inland placers. The mining of monazite in the United States has been practically at a standstill since 1906, especially since the price for thorium nitrate was reduced by European manufacturers to such an extent that it could be imported more cheaply than it could be made here, and this in spite of an import duty of 25% *ad valorem* on the salt. In former years, especially previous to 1906, there existed considerable activity in the monazite belt of North and South Carolina and many hands were employed to mine the mineral. Since then practically no mining of this mineral has been done in these and other states where monazite occurs. It is believed that monazite can be mined in this country more cheaply than heretofore, provided more modern means are employed. Mesothorium can be obtained as a by-product from thorium nitrate manufacture and this may help the American manufacturer to utilize domestic resources at least to some extent.

In Technical Paper No. 110 of the United States Bureau of Mines, Mr. Karl L. Kithil gives a full description and references to occurrences of the mineral in this country and the methods used in the mining of monazite sand are thoroughly discussed, together with flow-sheets and other technical details. A short outline of analyses for thorium is given, as well as methods employed in the chemical manufacture of thorium nitrate and mesothorium.

Concentrates

Readers of the Mining and Scientific Press are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

Sulphuric acid weaker than 66°B., or 1.84 specific gravity, should not be put in iron drums, as they will be attacked by the acid.

A carborundum lining is used in the Rockwell double-compartment gold-precipitate melting-furnaces at the Belmont mill, Tonopah. To line one compartment costs $148, including labor.

Lubricating oil for internal-combustion engines must be of good quality, suitable for the particular engine, and supplied in correct quantity, while the lubrication system should be properly designed. The splash system is generally used.

A radiograph of a metal only gives the gross structure, and no information as to the 'grain.' It does, however, give valuable data as to the presence of blow-holes, slag inclusions, porous spots and defects of like nature, which could not be found otherwise except by cutting into the metal.

The saloon breaks up the monotony of the life in mining villages, and to compete with it or to replace it, it is necessary to find a force of equal or greater social value, according to a writer in the *Coal Age*. Such a place must be more than a house; it must be in a sense a home and have someone who will sustain and control its activities.

The length of rope to be allowed for a loop when attaching clips depends largely on the number of clips to be used, which in turn depends upon the loads to be handled. This length will vary from 30 to 35 times the diameter of the rope; that is, for a 1-in. rope, from 30 to 35 inches should be allowed for the short end after passing around the thimble.

Wood fuel is used for assaying at the Yuanmi mine, Western Australia, on account of the high cost of coke and charcoal. An increased grate area and depth of fuel is required in the crucible and cupelling furnaces. Comparing the cost of wood with coke and charcoal previously used, the longer life of crucibles and muffles, the saving is about $58 per month.

Range in the Lake Superior region is a term applied to a deposit of iron ore and the associated rocks. It originated from the finding of ridges or ranges formed by the wearing of the softer rocks while the hard rocks in which the iron ore is found made ridges, or low ranges. Now the term simply means deposits of iron ore, which are all known as 'ranges,' even if the ground where they occur be low swamps.

Cadger is defined by the Oxford dictionary as "a carrier, itinerant dealer in eggs, butter, etc., between remote farms and towns; street hawker, beggar, loafer." When an important mining company sent an order for "6 doz. cadgers" the above definition did not seem to fit. Only after much telephoning to various hardware dealers was an informant found who explained: "Know what they are? Why yes! We sell hundreds of them. They are a little pocket oil-can for miners."

Minnesota iron ores occur in vertical or steeply dipping lenses that have a maximum width of 400 or 500 ft. and a maximum depth of 1000 ft. Some of these lenses are more than half a mile long on the strike. The Mesabi range is 100 miles long and 1 to 3 miles wide. The Hull-Rust open-pit at Hibbing is the largest iron mine in the world; in 1913 its output was 3,500,000 long tons of ore. The iron ore of the Mesabi is contained in the Biwabik formation, which consists of ferruginous chert, iron ore, slate, iron silicates, and carbonate rocks. Its average thickness is 800 ft., but owing to the low dip it is exposed from a quarter of a mile to three miles wide.

Explosives may be defined as solid or liquid substances that under certain influences, such as heat or shock, resolve themselves instantly into a gas. The commercial explosives are all solids. The gas produced, expands by heat to several hundred times the volume of the solid matter and on the completeness and rapidity of the change depends the power of the explosive and its suitability for special purposes. Explosives are 'high' or 'low.' The high explosive requires a detonator, usually mercuric fulminate, while the low explosive needs simple ignition. Black powder was the original explosive and was made of villainous saltpetre, charcoal, and sulphur for 500 years. The first smokeless powder was invented in 1884 by Vieille in France. One of the latest powders, 'Turpenite' has a poisonous effect; it probably contains cyanogen.

Explorers in former years have been unable to determine longitude with accuracy, the error in determination frequently amounted to degrees. Wireless telegraphy apparatus that can be carried on the backs of men without difficulty now enables longitude to be determined with precision. The Bolivia-Brazil Boundary Commission used the following: (*a*) A seven-stranded aerial wire of phosphor-bronze 1200 ft. long. (*b*) A 190-turn box inductance, rolled in square form with bottom attached. This was used as a carrier for the outfit. (*c*) An ordinary type loose-coupled Martini jigger; oscillation transformer. (*d*) Two dry-cells. (*e*) One pair ordinary Schmidt-Wilkes telephones. (*f*) Several hastily made small inductance coils for use as necessary, according to length of aerial erected. The wire was stretched between trees, as high as possible and pointing to the station from which the signals were expected. With this simple apparatus signals were received from Washington and from Brazilian stations. The closeness of the longitudes thus determined is phenomenal. Two determinations of the longitude of Porto Velho were: from Manaos, Brazil, 4H 15M 38.7S W. of Greenwich; from Washington (one night only), 4H 15M 38.5S.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

TOLOVANA, ALASKA

CONDITIONS AND PROSPECTS OF THE NEWEST OF ALASKA'S GOLD DISTRICTS.

The Tolovana district is situated 55 miles northwest in an air-line from Fairbanks, and is the area included between meridians 148°20′ and 148°40′ and the parallels 65°20′ and 65°40′. The discovery was made on Livengood creek in about the centre of this area during the summer of 1914 by J. Livengood and J. Hudson, but news of the 'strike' did not become public until late in the fall, when, with true Alaskan spirit, everybody in the surrounding districts stampeded. Every creek in the district was located; a snow-road was built from Olness and a rush was made with dog-teams and horses. By the first of April 1915, good prospects had been discovered on Livengood, Wilber, and Olive creeks, all tributaries of the Tolovana river and also on Myrtle creek, a tributary of Livengood, also on Mike Hess creek, a tributary of the Yukon river, and on Alabama creek, which flows into the Mike Hess at present, but at a very recent time geologically was the upper part of Livengood creek and is separated from it at present by a flat ridge only a few feet higher than the bed of Mike Hess creek, which was no doubt a terminal moraine not very long ago.

There is a strong contrast between the topography of the Tolovana and Fairbanks districts. The country is more broken with narrow serrate ridges and steep slopes, mostly bare of timber at the higher elevations.

In the valleys there is an abundance of timber for present needs, and two saw-mills are already under construction on the Tolovana river within ten miles of the Discovery claim.

The rocks of this area are composed of closely folded slate, chert, quartzite, conglomerate, greenstone, and limestone, no doubt of the Paleozoic age, as they have the same general characteristics as rocks so classified by U. S. G. S. Bulletin 442, but this area has never been mapped.

The main ridges are bare of timber and moss. Changes in the rocks can be noticed at short intervals, from limestone to quartzite, then to slate. In one place on the ridge south of Livengood creek, typical 'pencil slate' as found in the Mother Lode region of California makes its appearance and farther on a dike of serpentine (greenstone) 300 ft. wide crosses the ridge and is eroded away for about two miles. This forms the bed of Amy creek, the upper tributary on the right limit of Livengood creek and it is this dike no doubt that furnished the greenstone gravel that is found in all the channels farther down.

Prospecting has been done continually for quartz veins, for it has been assumed by the prospectors that Livengood creek received its gold from quartz veins, as the creeks did in the Fairbanks district, but as no quartz-gravel is noticed and no veins have been uncovered the source of the gold remains a matter of doubt.

The bedrock is a silicious slate (argilite) which is very much fractured and cut by small quartz stringers varying in width from microscopic to as much as an eighth of an inch in width and at irregular distances apart. While these stringers usually show no signs of mineralization, the writer, Clarence Woods, was able, in several places, to see some sulphides, and in a few places the quartz stringers were entirely replaced by stringers of iron pyrite. From the wide distribution of this character of bedrock and the lack of any quartz-gravel, he was led to believe that time will prove that the gold was derived from the argilite, which forms the bedrock of the district.

Livengood creek is the principal creek at present. The gold-bearing part is about 10 miles long and from 1 to 3 miles wide, rim to rim. Gold is found practically anywhere along the present creek-channel, but not in sufficient quantity to attract much attention except on Lillian, the first gulch on the right limit, and on Ruth gulch, which flows into Livengood creek on the right limit at Discovery, which is five miles above the Tolovana river. Other work is being done along the present creek-channel, but so far nothing has been found that would pay.

At present there are three distinct pay-streaks on the left limit; on the first tier bench, Kinney and Franklin on Five Horse are taking out gravel and sluicing it. The results of their work cannot be determined until the clean-up. There are several other places along this bench that prospect, but no other works of any size. On the second tier bench on Six Above, Gustavison is taking out gravel with a windlass and dumping it directly into the sluice, but the pay-streak is narrow and it will require considerable work to determine its value. On the third tier bench, the main pay-streak has been located at intervals for about six miles and there are leases being let and work being done all along the line of this 'pay' and developments are being anxiously awaited.

At present the pay-streak is opened up in seven places and the results of panning are practically the same in each case, although in some places the pay is too narrow to work at a profit at present, but any of these places from Sixteen Above, where Allenwell & Batten have gravel worth $1.50 per square foot of bedrock, to One Below, where Hedstrom & Hudson have similar pay, it can be expected that pay-gravel in quantities will be opened up.

Harry Patterson and associates on the deep-channel claim on the third tier bench, opposite Six Above, have made the only clean-up so far reported and it amounted to 130 oz. valued at $2350, which gave an average of $1.50 per square foot of bedrock, which was about what was estimated. The gold is coarse, one nugget weighing over six dollars, and the pay-streak at this place is opened to a width of 140 ft., and is 80 ft. deep.

At present the gulches on the left limit will furnish water for sluicing, but as the camp develops it will be necessary to build a ditch from Mike Hess creek, which will furnish water for all future needs. A survey is being made for this purpose.

There are three ways of getting into the district. One is by way of Rampart, but the trail is dim and there are no road-houses. Only a few men come in this way, as there is danger of getting lost. Most people who 'mush' in come by way of Olness, a point on the Tanana Valley railroad, 21 miles from Fairbanks. This is known as the Olness trail and it is 55 miles to Livengood creek. To any novice who desires to try a difficult 'mush,' the writer can recommend this 55 miles of 'nigger-heads.' At present it is impossible to get pack-horses or teams over this trail, but last winter they say it was a very good snow-road, and all the equipment and supplies used were brought in over it by dog-teams or horses.

Surveys are now being made for a good winter-road from Fairbanks.

The water-route is used altogether for freight at present. The rate from Fairbanks to the mouth of Livengood creek

is $7 per 100 lb., and from the river to Discovery $3.50 per 100 lb. for packing on horses. Good-sized loads can go direct from Fairbanks to the log jam, 120 miles above the mouth of the Tolovana river. Here a portage of 2100 ft. is made and the remainder of the trip, about 55 miles, can be made in small gasoline launches or poling boats.

As the demand for freight increases, the rate will be materially cut and the mouth of West Fork will be the end of the boat-haul, as there is now a wagon-road being built to Discovery, a distance of 11 miles.

Food and supplies have been hard to get owing to the delays in shipment, but the prospectors have managed to get along and the occasional visitor can always obtain a bed and good substantial camp-food with the addition of a choise cut of moose-meat. As long as the moose last Tolovana can always have fresh beef, and that is more than can be said of many places in Alaska and elsewhere.

The district will undoubtedly produce considerable gold, but owing to its source the pay-streak may be spotty. From all indications the district should make good by itself, as no outside capital seems to be interested.

VICTORIA, BRITISH COLUMBIA

PRESENT MINING ACTIVITIES TROUGHOUT THE PROVINCE BRIEFLY DESCRIBED.

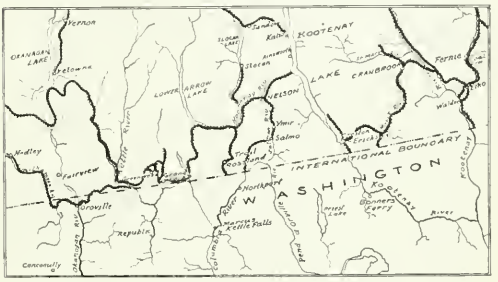
The extent to which the War has affected production of ore in the Kootenay districts is shown in the following table, which gives receipts at the Consolidated Mining & Smelting Co.'s plant at Trail, to which is usually shipped most of the ore and concentrate produced in East and West Kootenay, excepting zinc ore and concentrate, which usually find a market in the United States:

Districts.	7 months of 1915, tons.	7 months of 1914, tons.
East Kootenay	25,314	14,404
West Kootenay:		
Ainsworth division	3,843	11,856
Slocan division	4,006	12,549
Nelson division	2,182	17,119
Trail Creek division (Rossland)	198,191	145,386
Lardeau division	85	84
Boundary	428	283
Kamloops	413	289
Coast	128	828
Total from B. C. mines	234,590	202,798
Alberta	10	.....
State of Washington	17,479	9,464
Total	252,079	212,262

The figures show a net gain of about 40,000 tons to the end of July 1915.

In regard to the decreases, the mines in Ainsworth division that were chiefly affected by the low prices of metal in August 1914, were the Bluebell, producing lead ore, and the Highland and No. 1, silver-lead ore. Of these, the No. 1 resumed shipping ore last March; and at the Bluebell preparations for resumption are in progress, so that only the Highland of last year's larger producers remains off the shipping list. Of the 8500 tons decrease from Slocan mines, 7500 tons was the difference in output of the Standard silver-lead mines, which a few weeks ago resumed its former shipping rate, so that the Slocan division is now making nearly as large an output of ore as it was before the War. Of the 15,000 tons shortage from mines in Nelson division, 13,000 tons is the difference in output of the Silver King, a silver-copper mine controlled by the Consolidated company, which will resume production from it whenever it will be advantageous to do so. Of the increases mentioned above, that from East Kootenay was from the Consolidated company's Sullivan Group lead mine, which in recent years has taken the place of the same company's St. Eugene mine, also in East Kootenay, which previously had been the largest producer of lead in Canada; while that from Trail Creek division was from the Centre Star-War Eagle group, and the Le Roi, all gold-copper mines owned by the Consolidated. The Washington State mines that have this year shipped more freely to Trail are nearly all situated at Republic, Ferry county. They were mostly either inactive during the first half of 1914, or were shipping ore to Boundary district smelters.

The quantity of ore received at the Trail smelter is, however, not the only criterion of progress in mining in the Kootenay and Boundary districts; in fact this does not indicate the position at Boundary mines, as only small shipments of ore have been made from that district to Trail in recent years. The Granby Consolidated company, which is by far the largest producer, has been operating during the current year for several months with its mines and smelters at full ordinary capacity. Published figures show the production of copper from the company's mines at Phoenix to have been during the second quarter of the year more than 4,700,000 lb., compared with only about 3,000,000 lb. during the first quarter. Esti-



PART OF BRITISH COLUMBIA.

mating the output in July at about 1,700,000 lb., the approximate total for seven months, to August 1, may be placed at 9,400,000 lb. This does not include the output from the company's Hidden Creek mine, which is in the Coast district.

One furnace was blown in at the British Columbia Copper Co.'s smelting works at Greenwood in July. Since then the shipment of blister copper to New Jersey has been resumed, after a suspension of production of 11 months.

The only property in the eastern part of Boundary district that continued production in spite of the War is the Jewel gold mine near Greenwood. The 15-stamp mill was operated without interruption.

In Similkameen, in the western part of the area officially known as the Boundary district, the Hedley Gold Mining Co.'s Nickel Plate mines and 40-stamp mill have steadily maintained their customary output of between 3000 to 3500 oz. of fine gold per month. Additions to plant are being made, including a tube-mill, four large treatment vats, a third Oliver filter, and various accessories. The mines are well developed to maintain a regular output.

Reverting to Kootenay district, a brief summary of mining progress is as follows: While there has been some improvement in the demand for coal and coke, colliery employees are not yet working full time. It has been announced that money has been secured for erecting a by-product plant at the coke-ovens of the Crow's Nest Pass Company.

Metalliferous mining in East Kootenay is still of little importance, save only at the Consolidated company's Sullivan Group mine, the output of which has been substantially increased, and at which the outlay on development work continues to be comparatively large. The latest work is a long cross-cut, to provide a protected outlet from the mine, so that

in winter ore may be conveyed to the railway under cover instead of by means of an aerial tramway, as at present.

In several of the mining divisions of West Kootenay there has been gradually increasing activity until many small mines as well as a few larger ones are giving employment to a considerable number of men.

Experiments in concentration of ore from the Silver Hoard have recently given good results. The Florence Mining Co. has opened silver-lead ore that requires facilities for concentrating. This is being considered. On the south fork of Kaslo creek, the Cork-Province mine and concentrator are now producing silver-lead ore and concentrate.——The Utica mine will ship more ore this season than last.——The Whitewater group, now known as the J. L. Retallack & Co.'s mines, is also being worked.

In Slocan division, the Lucky Jim is shipping ore to the Ivanhoe mill at Sandon. The Rambler-Cariboo mine has considerable good ore in sight and is keeping its mill fully supplied.——Development of the Payne is being continued with encouraging results.——The Slocan Star has good-grade silver-lead ore in its lower levels, in addition to an ample supply of concentrating ore available for its mill.——The Ruth-Hope mill is being prepared for continuous operation on ore from that property. The Surprise is sending ore to the Ivanhoe mill and shipping to the United States both silver-lead and zinc concentrates.——Development of the Noble Five continues. A dozen or more small properties throughout central Slocan are having more or less work done on them.

Of mines near Slocan lake, the Standard is the largest producer, and an early resumption of payment of dividends by the Standard Silver-Lead Mining Co. is promised.——The Hewitt mine of the Silverton Mines, Ltd., is maintaining an output equal to the full capacity of the concentrating plant.——Work has been undertaken on the Wakefield and Galena Farm, both of which had been idle for several years. Lower down the lake, the Enterprise, Ottawa, and other well-known mines are each employing a few men.

In the Nelson division present production is chiefly from the Queen and Motherlode gold mines, at Sheep Creek, and from two or three lead mines in the neighborhood of Salmo. There are several small producers of gold in various other parts of this division, and work is also being done on some copper-gold claims; while in the southern part the development of a molybdenite property has been undertaken.

In the Coast district, coal mining is not yet in a flourishing condition, the demand for coal being insufficient to keep the miners fully employed. Copper mining has become much more important than in past years, both at the Britannia mine, in Vancouver mining division, and at the Granby Consolidated company's Hidden Creek mine, near Observatory inlet. The company is putting in a fourth blast-furnace at Anyox, distant a mile or so from its Hidden Creek mines, and is stated to be smelting, with three furnaces, about 2000 tons of ore per day. Copper ore is being shipped from near Hazelton to the Granby works.

Much important construction work and the installation of plant and machinery for the equipment of extensive new underground workings in the mine, and a 1000-ton unit of a new concentrating plant are approaching completion at the Britannia.

Silver-lead claims in other parts of Omineca division are being worked.——Development of the Surf Inlet gold mine, on Princess Royal island, is being continued. The most important mining in other parts of the Coast district is that at the gold-copper mine of the Tacoma Steel Co., on Texada island.

No mention has been made above of placer-gold mining in Cariboo and Atlin fields, but in both there is much activity and an average season's output is expected.

The Pontiac and Sunrise lead-zinc properties between Ainsworth and Kaslo will probably be controlled by C. F. Caldwell of the Utica mine, near the latter place.

TORONTO, ONTARIO

Dome Dividend.—McIntyre Litigation.—Imperial, Dome Lake, Pike Lake.—Cobalt Notes.—Canadian Zinc Co.

The Dome output for July, $131,928, from 28,300 tons of ore, is the best since the beginning of 1914. A dividend of 5% per quarter is to be paid, making an annual disbursement of $800,000.

During July the McIntyre treated 9410 tons of ore averaging $7.89 per ton. The recovery was 96%, and working cost $4.70 per ton. The net profit was $27,600. The general manager states that the large orebody cut at 500 ft. assays $9 per ton. Litigation has been started over the purchase by the McIntyre of the Pearl Lake. An action has been brought by Louis Streuber on behalf of himself and other creditors of the Pearl Lake against B. E. Cartwright and the McIntyre company to have the date set aside. The plaintiff alleges that the sale of the assets of the Pearl Lake company to the defendants for $47,733 was negotiated by a man who acted as a trustee for the creditors and shareholders, and was at the same time, solicitor for Cartwright, and also that Cartwright received 1,000,000 shares of the McIntyre and McIntyre Extension companies, without the knowledge of the assignee, the shareholders, or the creditors.

On the Imperial, a high-grade ore-shoot has been cut at 100 ft. The ore contains free gold and is heavily mineralized. It is stated that the vein is 2½ ft. wide and assays about $15 per ton.

The Dome Lake shipped a gold bar of 200 oz. last week. The mine is reported to be much improved by recent developments at the 400-ft. level, where samples assay as high as $30 per ton.

Two shafts are being sunk on the Pike Lake property, and a large porphyry dike that crosses one of the claims is being stripped.

Cobalt, which has been depressed on account of the low price of silver, now shows some improvement; large shipments of bullion have been made. Several old prospects have been re-opened recently; new companies have been organized. The Gould leasehold, owned by the Peterson Lake, which has been held by several companies, has been turned over to the Mercer Silver Mines, Ltd. The property will be thoroughly explored. W. E. Segsworth is managing director, and A. C. Bailey, manager.

The Kerr Lake has purchased a controlling interest in the Caribou Cobalt, the latter company owning all the stock of the Cobalt Comet, the properties of which adjoin those of the Kerr Lake.

The Canadian Zinc Co., recently incorporated, has acquired a large industrial plant at Welland, Ontario, and contracted for a supply of 1000 hp. of electricity for electric smelting. The first zinc ore treated will be from the United States, but it is proposed ultimately to secure a supply from the mines at Nottingham, Quebec.

At Porcupine the Dome Lake has just shipped its seventeenth bar of gold, estimated to be worth $4000. Development work is being carried on extensively. At the 400-ft. level grab-samples are stated to assay $29 per ton.——It is almost certain that the West Dome property will be re-opened shortly after the meeting of the shareholders to be held on August 20.——A diamond-drill outfit has arrived for the Moneta company.——At the Imperial mine, at the 100-ft. level, a vein has been cut having a width of 30 ft. Much of the ore shows free gold. Two shifts are working.——In the Deloro district, the Porcupine Premier has started to re-open its property. In the past week 14 men have been engaged.

At the Alexo nickel mines near Porcupine, the development indicates possibilities of large orebodies. With a small working force and plant, production for the first six months of 1915 has been 5700 tons of pyrrhotite ore, averaging 5% nickel, together with small quantities of platinum and palladium.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

Cordova

Ore and concentrate shipments from the Kennecott company's mines totaled over 9000 tons in July. Most of this came from the Bonanza mine, some of which was 70% ore, the remainder being concentrate. The Jumbo produces 50% smelting ore, and 10% concentrating ore. The Beatson on Latouche island contributes to the output. The yield of the properties this year will be about 70,000,000 lb. The cost is said to be below 5c. per pound.

Juneau

The Treadwell 240-stamp mill started using water power on August 10, the first time for nearly two months.——On August 12, the material on which the Alaska Gastineau company's wharf at Thane was built, slipped and carried away about 10,000 sq. ft. of the wharf. Damage is about $5000. At the end of the wharf there is 30 ft. more water than before the accident. The structure will be re-built. Storms have been a nuisance lately.

Nome

In the case of George D. Schofield *v.* the Nome Consolidated Dredging Co., filed in the District Court on July 24, 16 distinct causes of action are given and the plaintiff asks for judgment on a number of time checks and promissory notes given by the defendant company in lieu of payment for labor and other contracted obligations and assigned to the plaintiff. The notes vary in value from $28 to $316, and total with interest about $2000. The complaint states that the defendant acknowledges the indebtedness, but has failed to pay. The Court is also asked to grant an attorney's fee of $400.

The Wonder and Bourbon dredges and the power-plant on lower Bourbon, were sold by the marshal on July 15. The properties were sold in satisfaction of a judgment obtained in the District Court recently in favor of a number of people represented by Ned Darling and Frank Thatcher as trustees. The purchase price of the properties, which were bid in by E. E. Powell, is to be $20,000.

ARIZONA

Cochise County

The Warren district is the scene of greater activity than at any previous time. Development at the Juniper Flats continues. The Juniper Flats Gold Mining Co. has installed a large crusher in its mill.

Experimenting continues on the ore at the Bunker Hill mine at Tombstone with favorable results. A great deal of construction and overhauling is under way at the property. The great air-compressor, installed by the Tombstone Consolidated, has been re-started. It will supply air for the hoists, the mill, and machine-drills underground. Water in the main shaft has been lowered 70 ft. There are 360 men employed.

Mohave County

A hoist compressor, jackhamers, and other machinery are being installed at the Big Jim company's shaft. When the shaft is down 400 ft. a cross-cut will be driven to cut the Tom Reed vein formation.——Good progress is being made at 200 ft. in the Ivanhoe Consolidated.——The Oatman company's shaft is still in ore which came in at 85 ft. The vein is widening and is of better grade. Chicago people have bought an interest in the property.

Pinal County

The Magma Copper Co. has issued a report to shareholders, dated May 27, 1915. The company's mine is at Superior. To February 1, 1915, a total of 12,311 ft. of development has been done. From this and some stoping there was 44,075 tons of ore extracted, averaging 8.19% copper, 9.37 oz. silver, and 60c. gold per ton. Copper is in the form of chalcocite. Shipments from this ore amounted to 13,250 tons assaying 17.91% copper, 21.52 oz. silver, and $1.80 gold. Net smelter returns were $640,000. This has been spent at the property. The vein has been developed at 500, 650, 725, 800, and 1000 ft. At the lowest depth the shoot is 275 ft. long, being 4.8 ft. wide, containing 14.34% copper and 13.12 oz. silver. There is also a foot-wall copper shoot of lower grade and a zinc shoot between the two. The greatest width of the mineralized zone at 1000 ft. is 60 ft. A new three-compartment shaft will be finished to 1200 ft. by October. Ore reserves are estimated at 95,000 tons averaging 7.6% copper, 8.15 oz. silver, and 56c. gold per ton. A concentrating and flotation plant of 4500-ton monthly capacity has been erected. It is connected with the mine by an aerial tram 2600 ft. long. The mill will not work to capacity until the new shaft is ready. In January and February 1915 it treated 5882 tons of ore, yielding an operating profit of $22,000 each month. Copper was sold at 14.75c. per pound. The haulage of concentrate was 13 miles by team and 17 miles by narrow-gauge railway to the Arizona Eastern line. The total cost was 6.9c. per pound of metal. Power is purchased from the U. S. Reclamation Service at $49 per horse-power year. The company controls the Magma Arizona Railroad Co., which has just constructed a 30-mile narrow-gauge line from the mine at Superior to Webster, on the Arizona Eastern road, 51 miles northwest of the A. S. & R. smelter at Hayden. The profit since January 1 is $78,474 and total surplus $112,541.

Yavapai County

The new smelter at Clarkdale is treating 1400 tons of ore daily. No. 3 blast, and No. 2 reverbatory-furnace, were blown-in last week. This will increase the capacity to 2500 tons.

Work in the Crown King district has been confined during the past three or four years to small syndicates driving adits on veins. Several of them have opened good gold, silver, and lead ores, including the Nelson, Montezuma, Lincoln, Gladiator-War Eagle, and others. As has been mentioned before, it is proposed by Colorado men to drive a long adit to cut most of the veins at depth.

CALIFORNIA

The exact time and place for the meetings of oil operators called by the State Mining Bureau to discuss the new law regulating the drilling of wells is as follows: Coalinga, August 23, Growlers Club, at 3 p.m.; Bakersfield, 25th., Board of Trade, 3 p.m.; Taft, 27th, Petroleum Club, 8 p.m.; Los Angeles, 30th, Bullard building, 2 p.m. (Supreme Court Room); Santa Paula, 31st, City Hall, 1:30 p.m.; Santa Maria, September 1, Office Producers Cementing Co., 3 p.m.; and San Francisco, 3rd, 10th floor Commercial building, 2 p.m.

Amador County

Extensive repairs are being made at the North shaft of the Kennedy mine. An iron water-pipe is being replaced by banded wood-stave pipe.——At the old centre of Aqueduct, J. McFadden has opened rich ore. Renewed interest is being taken in the district.

Butte County

It is reported that the Natomas Consolidated company has designed a boat to re-dredge the Oroville field. No. 1, now working at Thermalito, is to experiment on old tailing at an early date.

It is probable that the Great Western Power Co. will absorb the Oro Electric Corporation, a subsidiary of the Oro Water, Light & Power Co., but the dredges and gravel areas will not be sold.

It is reported that rich quartz has been opened in the Eureka mine, near the Mineral Slide gravel mine near Magalia.—— Some good gravel has been opened in the Oro Fino.

Calaveras County

At the Calaveras copper mine at Copperopolis there are 90 men employed. No. 7 level south drift, north face, shows 9 in. of 18% ore. The remainder of the face is good mill ore.

Inyo County

(Special Correspondence.)—The Wilshire Bisbop Creek company reports that as the result of operations since the resumption of work on Jnne 1, a little over $18,000 has been realized from sales of bullion and concentrate. The latter assays slightly over $250 per ton; they are sent to the U. S. S. M. & R. Co., Utah. The ore yields about $13 per ton, with 84% extraction. The loss is entirely in free gold, and the installation of a slime-table is expected to reduce losses considerably. The ore-shoot averages 26 ft. in width of this, about 9 ft. is $7 ore, and under present circnmstances is not profitable, only 17 ft. wide being mined.

Bishop, August 18.

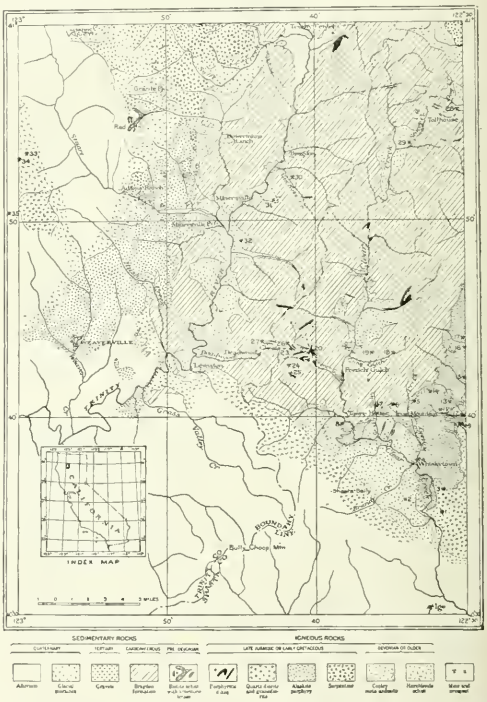
Nevada County

Ore worth about $290,000 is stated by the North Star Mines Co. to have been stolen from its property during the past year or two. Last week two men were arrested at Sacramento with ore worth $1500, alleged to have come from the North Star mine.

Shasta County

The Balaklala Copper Co. has arranged to deliver 250 tons of ore daily at the Mammoth Copper Co.'s smelter at Kennett. S. A. Holman, Jr., is superintendent, and will employ at least 125 men when the mine is re-opened. A compressor, motor, and transformer at the Mammoth company's Stowell mine, three miles southwest of Kennett, were destroyed by fire on August 20. The plant will be renewed.

The pocket deposits of the Klamath mountains are described in the April-May issue of *Economic Geology* by Henry G. Ferguson. The mining districts of these ranges are less known than those of the Sierra Nevada. Shasta, Trinity, and Siskiyou counties produce a total of about $1,750,000 in lode and placer per year. Besides these there are gold deposits of another type, the so-called 'pocket' deposits. Their occurrence in the Weaverville quadrangle is entirely different from the usual vein deposit. Primary mineralization, as distinguished from the secondary process that produced the pockets, followed the quartz-diorite and grano-diorite intrusions. Pockets are found throughout the lowlands of the Klamath Mountain region, where the streams cut below the 4000-ft. plain, but not in the higher mountains. They may occur wherever the contact of black slate with another formation, generally meta-andesite, is exposed, but are not common in the immediate vicinity of the more important primary veins. None is found near the grano-diorite masses. The gold does not occur in quartz but in small calcite lenses between the meta-andesite and slate, between the calcite and slate, and in small specks along the contact without any gangue. Rarely do the pockets occur so close together as to justify continuous mining. The 'pocket-hunter' usually gouges out a pocket, from one dollar to several thonsand dollars, and then moves on to prospect elsewhere. No estimate is possible of the amount of gold obtained from pockets. Old workings are found all along the slate contact, and the most extensive sluicing has been done along those streams that cross the contact, and in many of them no placer work has been done upstream from the contact. The older gravels of the Weaverville basin are singularly deficient in quartz, compared with those of the Sierra Nevada, and probably much of the former's gold-content has been derived from pockets. The Mad Mule and Five Pines mines produce their gold entirely from pockets. The former is three miles north of Whiskeytown, the profitable workings extending from 2300 to 2900 ft. elevation. The pockets occur along the contact of



GEOLOGIC MAP OF PART OF THE WEAVERVILLE QUADRANGLE (U. S. GEOLOGICAL SURVEY).

Mines and prospects as follows: 1. Mt. Shasta. 2. Mountain Monarch. 3. Mascot. 4. Gambrinus. 5. Mad Ox. 6. Mad Mule. 7. Truscott. 8. El Dorado. 9. Minnesota. 10. Hidden Treasure. 11. Iron Mountain. 12. Little Nelly. 13. Hornet. 14 Lone Star. 15. Hardtack. 16. Balaklala. 17. Great Verde. 18. Gladstone. 19. American. 20. Franklin. 21. Milkmaid. 22. Washington. 23. Niagara. 24. Summit. 25. Brunswick. 26. Accident. 27. Brown Bear. 28. Delta. 29 Stacey. 30. Five Pines. 31. Mountain View. 32. Fairview. 33. Globe. 34. Bailey. 35. Craig.

the slate with a dike of diorite porphyry. Calcite occnrs in irregular patches. The largest piece of gold extracted was in the form of a plate ¼ in. thick, weighing over 100 oz. Gold also occurs in much smaller masses entirely within the calcite, in small replacement veinlets, generally along the cleavage directions. The Five Pines and Surprise mines are situated about 1½ miles above the junction of Van Ness creek and Trinity river. From 1896 to 1912 the gold output was $275,000. Opposite them are the Keno and Emma prospects. The Surprise is the best developed. Pockets are fonnd on the slate and meta-andesite contract. The best pocket in this mine yielded $45,000 in a distance of 44 ft. The discussion of these pocket deposits is interesting, and should be secnred by California miners.

Siskiyou County

(Special Correspondence.)—The Rollin Mining Co. has increased its working force at the Black Bear mine, and is pre-

paring to operate more machine-drills. Good ore is showing in the bottom levels.

The old mill at the McKeen mine, near Callahan, is being equipped with cyaniding machinery, and its capacity increased to 25 tons daily. Mine developments are satisfactory, the main vein being developed several hundred feet, and showing an average width of 30 in. Three other veins have been cut, and are to be developed at once. Eighteen men are on the payroll. The McKeen was purchased last summer by J. R. McKinine and associates of Los Angeles.

The Victory Gold Mines Co. is erecting a sawmill at its property near South Russian creek, and is rapidly completing erection of the quartz mill. Crushing will probably start before the end of September.

Work is proceeding quietly at the Highland mine on Russian creek. The company is composed of Dutch people, and the property is operated along the most rigid lines of economy. John Mattern is superintendent.

Mining is active in the vicinity of White Gulch, with several important quartz discoveries reported. Near the Lanky Bob mine an ore-shoot assaying about $50 per ton has been discovered by A. J. Tellis and Bert Finley. It is about 12 in. wide, and getting wider.

The Hickey mine has good ore, and is being vigorously worked by Means & Neilon. The ore is coming from the Hickey vein which has produced well in past years.

Small shoots of good ore have been found recently in the Baldwin, Towne, and other claims.

Yreka, August 15.

Yuba County

According to J. F. Sheldon of the *Boston Financial News* No. 14 dredge of the Yuba Consolidated yielded 336 oz. of gold during a recent week. This was valued at $6300. He saw this metal melted.

The Yukon Gold Co. has acquired control of ground adjoining the Yuba Consolidated estimated to contain $4,000,000, according to drill-holes. A large dredge has been ordered, production to commence at the end of the year.

COLORADO

Fremont County

It is reported that the smelter at Florence, belonging to the Rocky Mountain Smelting Co., which has been idle for 10 years, will resume operations as a subsidiary of the U. S. S. R. & M. Co. H. H. Utley of Denver has an option on the plant.

Eagle County

Uranium and vanadium ores have recently been discovered about eight miles from Eagle, and all the surrounding area has been staked.

Lake County (Leadville)

The pumps at the Penrose shaft are again working at full capacity.——The zinc-oxide plant is producing from 30 to 40 tons per week, the company receiving good prices for the product.——The Iron-Silver company has just distributed a dividend of $50,000.——Rich zinc carbonate has been opened in the Weston Pass district by the Riach Bros. Water has prevented deeper work being done.——The 10-stamp mill at the Gordon-Tiger is nearly complete. High-grade zinc concentrate will be produced.——A large quantity of rich gold ore continues to be developed in the St. Louis adit.——The Valley adit is in 1300 ft.——The Yak company has secured a 10-year lease and $600,000 bond on the Alladin claims at the foot of the Mosquito range. The Yak tunnel may be extended to this property.——A large hoist is being installed at the Garhutt, also a 15-drill air-compressor. The output of gold ore is 200 tons per day, worth nearly $20 per ton. A 200-ton mill is being planned. John Cortellini is manager.——The Molybdenite mine is sending 1000 tons of ore to the Leadville District mill.

Ouray County

The Camp Bird company reports as follows for the second quarter of 1915: development, 668 ft.; stoping, 12,860 cu. ft.; ore broken in stopes, 15,188 tons; ore treated, 7626 tons; revenue from bullion and concentrate, $187,992; working expenses, $78,720; profit, $130,000 plus $53,000 from the Santa Gertrudis company of Mexico. It is estimated that broken ore in stopes will yield a profit of about $200,000.

San Juan County

The Silverton district shipped 45 cars of ore during the past two weeks, the largest quantity for many years. The Sunnyside mill sent a train-load of zinc concentrate. This product was made by the Huff electrostatic separators. The plant is being enlarged.——The Hamlet mill, using flotation, has been started. A. E. Ritter is manager of the mine.

Teller County (Cripple Creek)

(Special Correspondence.)—The district generally is quiet at present, but an optimistic feeling prevails. Owing to heavy rains during the past 10 days, surface work, so far as dump lessees are concerned, has been almost at a standstill. Considerable surface prospecting has recently been done on Tenderfoot hill, owing to several rich discoveries in that vicinity.——A rich development was recently made in the Hondo property, situated between the Portland and Golden Cycle properties. It is reported that the vein is more than 10 ft. wide. In the middle is a high-grade streak of smelting ore; the remainder will make a good grade of mill ore.——At the annual meeting of the Blue Flag Gold Mining Co., recently held at Denver, John F. Erisman was re-elected president.——At the annual meeting of the Modoc Mining & Milling Co., held at Pueblo, F. R. Frankenberg, Sr. who has been president and general manager since its incorporation in 1893, retired from the presidency. Wardner Williams of Pueblo was elected president.

Cripple Creek, August 20.

IDAHO

Shoshone County (Coeur d'Alene)

A new high-grade zinc shoot has been cut in the Interstate-Callahan. This is distinct from the orebody in No. 6 adit. A cross-cut from the 1200-ft. level of the Success has also opened rich zinc ore. Good shoots have recently been developed at 500, 600, and 860 ft. The August output of concentrate will be about 2000 tons, also 500 tons of lead concentrate. An 8-cent per share dividend, equal to $120,000, is probable for September. An aerial tram from mill to railway, 1300 ft., has been ordered. This will reduce transport 50c. per ton.——At 400 ft. depth in the Marsh the cross-cut is in 475 ft., and the Got-Em-Now vein should be cut in another 150 ft. The daily advance is 10 ft. The three-compartment shaft is down 900 ft. ——On September 15 the Federal company will pay $1 per share on the preferred stock, a total of $120,000. The total for 1915 will be $360,000, and $15,045,545 to date.

Antimony mining in the Pine Creek district is of importance. The Old Antimony mine is being unwatered with T. W. Faulstich in charge. Some rich ore has been shipped in the past. ——T. Brown and J. Finnel are busy opening their mine.—— In Ross gulch C. Pearson is driving 200 ft. to cut a shoot showing on the surface. Some ore has been sent to Salt Lake City. ——At the Constitution there are 18 men employed. This is a zinc mine, and ore is being shipped.

MICHIGAN

Houghton County (The Copper Country)

Fire started at a depth of 100 ft. in No. 2 shaft of the Centennial mine last week, and spread up to the shaft-house, burning the wood and motors in the steel ore-house. Oxygen helmets were used with advantage. The production will not be curtailed, as No. 1 shaft will take care of this.

A second mill test of ore from the New Arcadian was recently completed at the Franklin mill. From 841 tons the yield was 34.2 lb. per ton of mineral, against 1870 tons of 31.5

lb. ore in the first run. A great deal of this ore came from the 900-ft. level. The results are considered satisfactory.

MISSOURI

Jasper County

Production of the Missouri-Kansas-Oklahoma region in the week ended August 14 was as follows: blende, 4588; calamine, 326; and lead, 847 tons, averaging $66.48, $53.85, and $51.35 per ton respectively. The total value was $365,870.

At the What Cheer mill, at Prosperity, there are 29 motors, each driving separate machines. The plant has a capacity of 250 tons in 10 hours. Ore is mined at a depth of 185 feet.

The chief of the bureau of State mine inspection, George Hill, has been investigating mining conditions in the Joplin district. He was accompanied by Lee Burch, the local inspector. Mr. Hill found things satisfactory.

Under the direction of W. N. Squires the Franklin company's 300-ton mill north of Duenweg was erected in seven weeks. A 165-hp. Bessemer engine drives a compressor, and one of 150 hp. drives the mill. A centre-fed 350-ton hopper is a feature in the plant. Rolls are 36 and 30-in. diameter. Two 36 by 48-in. 5-cell rougher-jigs, one 6-cell cleaner-jig, and one sand-jig complete the equipment.

MONTANA

Silverbow County

The Anaconda company has started pumping at the Nettie mine, several miles west of Butte. Work was stopped last year on account of the metal market. The shaft is 450 ft. deep, connected with extensive workings. The flow is 1500 gal. of water per minute. The Nettie has been a large silver producer, but zinc has largely displaced it at depth.

The Butte & London shaft has been unwatered to 1100 feet.

NEVADA

Elko County

The Jarbidge district is active and encouraging returns are being made. The Bluster 10-stamp mill is earning between $5000 and $7000 net per month. A power-plant is to be installed, and a cyanide-plant will be added. Amalgamation is recovering about 70%. Over 40,000 tons of ore has been blocked out in the mine. An aerial tram carries ore 3400 ft. to the mill.——A small stamp-mill is to be erected at the Flaxie mine.——The Pick & Shovel company is building a plant.

Esmeralda County

A three years' lease has been secured on the Bonnie Claire company's mine and 20-stamp mill, 38 miles south of Goldfield, by the Quigley Reduction Co., headed by J. D. Quigley and others of Los Angeles. Previously the Jumho Extension company sent its ore here to be treated. The plant will treat custom ore, and motor-trucks will haul ore from mines at Gold Mountain, Tokop, Hornsilver, and other centres. One of the principal shippers to the mill will be J. W. Dunfee, who is working the Orleans mine at Hornsilver, owned by a French concern. Every four days he is at present sending 50 tons to the Belmont plant at Millers. The Quigley company has also resumed mining at the Hard Luck claims of the Bonnie Claire.

Humboldt County

Antimony ore shipments from various points in this county are estimated at $10,000 during the past two months.

A 16-hr. run at the Seven Troughs Coalition mine last week yielded $2500, four days gave $9000, and $12,000 from six days' work. The August yield is expected to be about $50,000.

The Rochester Mines Co. has purchased the Big Four lease on Block 1 of the Crown Point claim. The claim has been producing 50 tons of $25 to $30 ore daily, the total output being over $400,000. An extensive shoot is being mined from the winze between 300 and 400 ft. depth. A hoist is to be installed at the winze, which will be sunk another 300 feet.

The Lincoln Hill Mining & Milling Co.'s two-stamp mill produced $5200 in July. Four veins have ben cut in two adits.

At Willard, the new gold centre, the Willard Cousolidated has started work in two places. It has also taken over two important leased claims. Shafts are to be sunk. San Francisco people are behind the concern.

UTAH

Beaver County

The 500-ton plant to treat about 1,000,000 tons of copper tailing at the Cactus mine is expected to be ready for work in about two weeks. A flotation process is to treat the 0.75% material.

Emery County

A good deal of copper ore has been developed in the Copper Globe claims, 35 miles southeast of Ferror, a company is to be formed, and probaly a reverheratory-furnace erected. E. J. Rhodes of Eureka is largely interested.

Juab County

A new orebody in the May Day is yielding ore returning upward of $70 to $80 per ton.——The new Knight-Dern mill at Silver City is to treat the large tailing dump at the Eureka Hill mill.——The A. S. & R. Co. has nearly removed the Sioux mill dump at Mammoth to its smelter at Garfield.

Salt Lake County

The Ohio mill is treating about 2400 tons of copper ore daily, and 200 men are employed by the company. The Empire Trust Co. of New York has started suit against the Ohio Copper Co. to foreclose a mortgage given to secure $2,000,000 worth of bonds issued by the latter, and also to investigate other matters.

The Salt Lake Stock and Mining Exchange had the busiest day in years on August 18, when 136,100 shares, valued at $51,872, changed hands. The largest interest was in Alta and Cottonwood district's properties.

Great actiivity continues in the Alta district.——Ore has been cut in the Emma mine assaying 56% lead and 175 oz. silver per ton.——In the Little Cottonwood district the Wasatch Mines Co. is to start an adit to cut the orebodies at depth. It will be about 5000 ft. long.——The Secret Mining Co. is driving an adit to cut the dike and limestone-quartzite contact.

The Montana Bingham Consolidated drainage, transportation, and development tunnel is in 4000 ft. Five veins have been cut, the last assaying 3.2% copper, 31% iron, 4.92 oz. silver, and $1.20 gold per ton. Good results are expected in the next 1500 ft. of driving.

Tooele County

The Ophir Mines Development Co. has been organized to develop the old productive deposits of ex-senator W. A. Clark at Ophir. Several million dollars worth of ore has been extracted from the property. The district has yielded $20,945,000 up to 1915. Present producing companies are as follows: Ophir Hill Consolidated, Lion Hill Consolidated, Buffalo Consolidated, Hidden Treasure, Eureka Ophir, Cliff, and Mono Development.

Washington County

(Special Correspondence.)—Activity is increasing at Goldstrike. The Hays-Monette interests have concluded the purchase of the Dora Jane claims, considered among the best in the district. A contract has been awarded for development on an extensive scale. It is reliably stated that these people have secured options on several other properties.——Recently two new companies have been formed to operate in Goldstrike; the Goldstrike-Peepstone company will begin development work on its property in a few days; the Goldstrike-Virginia Mining company, has work well under way. The last named company has acquired the Wild Cat and the Silver King claims; $11 ore has been found on both these properties.

——At the Primers, under lease to the Lund Bros. of St. George, Utah, where work has been done for two months, high-grade ore has been opened where the vein was cut in a drift from the 50-ft. shaft. Ore averaging $100 per sack, is being sent to Salt Lake.——The Goldstrike Bonanza company, has found high-grade ore; several tons have been dispatched to Salt Lake City.——The Bee Bee is crushing ore that averages, according to last assays, $37.40 per ton, at the three-stamp mill at Goldstrike. Several thousand tons of this ore is already blocked out.——On the Red Bull or Evans group, where good low-grade ore has been found on the surface by prospecting, development has been started.

Goldstrike, August 7.

CANADA

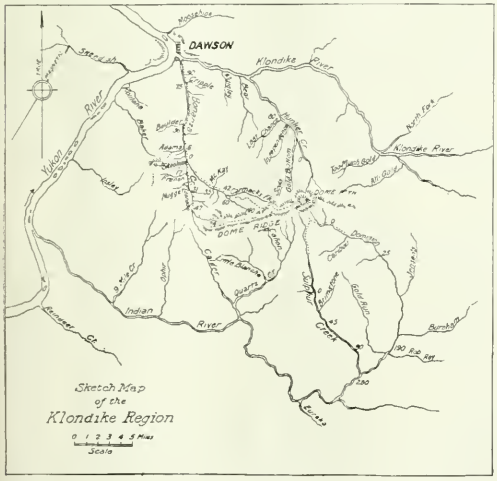
Ontario

In July the Hollinger mill treated 35,728 tons. Of this, 25,076 tons of $9.24 ore was from the Hollinger, and 10,652 tons from the Acme. The profit was $124,222. Costs were $3.73 per ton. The cross-cut at 425 ft. is only 125 ft. from the Middleton orebody.

At the Dome Lake mine $18 to $20 ore is being mined at 400 feet.

Yukon

At the end of July the Yukon Gold Co. lost by fire 3500 cords of wood worth $45,000. This was stacked on claim 45



and was being used for thawing gravel along Bonanza creek.

With 31 pages, including 11 plates and a map, Museum Bulletin No. 15, geological series 26, the Department of Mines at Ottawa issues a description of the Gay Gulch and Skookum meteorites by R. A. A. Johnston. These were found during gold-mining operations in two gulches tributary to Bonanza creek, near Dawson. The first was found in 1901 in a sluice-box on No. 6 claim, Gay gulch. It must have rested on bed-rock, or not more than 2 or 3 ft. above it. The meteorite weighed 483 grams. It had been subjected to attrition, and had no pittings as of recent falls. It contained 83.85% iron and 15.03% nickel. The Skookum was found in 1905 on claim No. 7, Skookum gulch, 3½ miles from the other meteorite. It was discovered 65 ft. below the surface, 2 to 3 ft. above bed-rock. It weighed 15.88 kilograms, and contained 80.65% iron and 18.2% nickel. A study of both points strongly to the probability that these irons are relics of a single meteoric shower which took place back in Tertiary time.

The American Electrochemical Society will meet in San Francisco during September. Seventeen papers have been accepted.

PERSONAL

Walter H. Weed is in Newfoundland.

Philip L. Foster of New York is here.

F. L. Ransome is here on his way south.

Lewis Shackleford is here from Junean.

George H. Garrey has returned to New York.

Leo Von Rosenberg was at Cripple Creek recently.

J. R. Geary is at the Clift hotel, on his return from Chicksan, Korea.

R. H. Ernest has returned to Round Mountain, Nevada, from Los Angeles.

Charles C. Selbie, of Pasadena, sailed on August 25 for the Philippine Islands.

Sanford Makeever, of New York, has been visiting the Juneau goldfield, Alaska.

George Otis Smith, Director of the U. S. Geological Survey, is due here on September 2.

R. R. Goodrich has been appointed professor of metallurgy in the University of Idaho.

John Gross has returned from Mexico and opened an office at 523 McPhee Bdg., Denver.

Alexander S. Proskey, of Rawhide, Nevada, has been spending a week at the Exposition.

Leon J. Pepperberg has returned from New York. He is going to Texas in September.

Colin Fraser has completed a geological examination of the Mt. Morgan mine, Queensland.

Robert M. Raymond, of Mexico City, and J. H. M. Shaw, of London, are at the St. Francis hotel.

W. J. Lakeland, recently with Burma Mines, in the Northern Shan States, is expected in San Francisco.

James F. McCarthy has been appointed manager for the National Copper Mining Co., at Mullan, Idaho.

G. Villaloros, director of the Panuco of San José de Gracia mines, is here from Mazatlan, Sinaloa, Mexico.

H. D. McCaskey, Chief of Mineral Resources Department, U. S. Geological Survey, is expected here next week.

F. H. Minard, who has been in Colorado and Nevada, spent a couple of days here, before returning to New York.

C. H. White, Professor of Mining and Metallurgy at Harvard, after a visit to Nevada, is returning to Boston.

Forest B. Caldwell, general manager for the Mexican Candelaria Gold Mining Co., of Durango, is in San Francisco.

H. T. Dickinson, assistant general manager to the De Beers Consolidated Mines, Ltd., is due at San Francisco from South Africa in October. His address will be care of Columbia University Club, New York.

H. D. Pallister has resigned as assistant Professor of Mining in the School of Mines of the Pennsylvania State College to become Professor of Mining and Geology in the State School of Mines, University of Texas, at El Paso.

R. P. McLaughlin, the State oil and gas supervisor, has appointed the following deputies: M. J. Kirwan in Fresno, King, counties and part of Kern county, stationed at Coalinga; E. B. Latham in Kern, Santa Barbara, and Ventura counties, headquarters at Santa Barbara; R. B. Moran in Orange, Los Angeles, and Ventura counties, with Los Angeles as head office; and Chester Naramore in charge of work in Kern and Ventura counties. The department of petroleum and gas is controlled by the California State Mining Bureau.

The American Chemical Society, California Section, will meet at Los Angeles on August 16 to 18, and at San Francisco August 25 to 28, inclusive. Papers will be read, and excursions are planned at each place.

THE MARKET PLACE

Weekly Summary of Metal Prices and Notes on the Markets.

Metal Prices

San Francisco, August 26.

Antimony	35 —35¾
Electrolytic copper	18½—18¾
Pig lead	4.85— 5.80
Quicksilver (per flask)	$95
Spelter	17 —17¼
Tin	37
Zinc-dust, 100-kg. zinc-lined cases	30

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, August 26.—The copper market is strong and excited; lead shows a tendency to panic; zinc is active, with a strong upward movement.

COPPER

Prices of electrolytic in New York, in cents per pound.

The Chile Copper Co. expects its plant to be at full capacity, 10,000 tons per day, by the end of October. A drill has cut 2.11% ore at a depth of 1530 feet.

The Inspiration Consolidated company expects its plant to be at full capacity, 15,000 tons per day, by January 1, 1916. Four of the 18 units are treating 1200 tons.

In July the Miami produced 4,087,611 lb. at a cost of 8.195c. per pound. The recovery was 79.26%. This is the first month that the yield was over 4,000,000 pounds.

In its financial year the Granby Consolidated produced 26,705,928 lb. copper, 415,806 oz. silver, and 32,129 oz. gold, about 70% of which came from the Anyox property. The June yield was 2,053,027 lb. from Anyox, and 1,573,902 lb. from Grand Forks.

The Allouez is producing at the rate of 10,000,000 lb. per annum, at 9c. per pound.

From its copper output alone the Tennessee company's profit is equal to 12% dividend for the year.

On September 7 the Quincy company will pay $2 per share.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.		Average week ending	
Aug. 19	47.12	July 14	47.56
" 20	47.37	" 21	47.47

The weakness in silver continues. On August 21 about 350,000 oz. was sent from San Francisco to China, also about 55,000 oz. from the Trail smelter in British Columbia. Exports from London to the Orient to August 4 totaled £4,393,500, against £2,955,000 in that period of 1914, a decrease of, say, 16,000,000 oz. Excellent rains were reported from different parts of India during the early part of August. The Punjab district has not received so much, but irrigation helps to minimize a lack of rain. The September rain is of more importance in that region. Depression in the Bombay silver market is attributed to dry weather, but the late rains are expected to result in a better demand for the metal from the Bazaars. There are 5800 bars of silver at Bombay.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

The Canadian government is to pay a bounty on zinc refined in the Dominion, the total bounty not to exceed $400,000. A plant will be erected at the Trail, B. C., smelter, and an electric smelter at Welland, Ontario.

The Commonwealth Government of Australia has granted permission to the Amalgamated Zinc Co. to sell 50,000 tons of concentrate (about 48% metal) to the Edgar Zinc Co. at £9 11s.6d. ($45.96) per ton.

TIN

Prices in New York, in cents per pound.

Monthly averages.

	1914.	1915.		1914.	1915.
Jan.	37.85	34.40	July	31.60	37.38
Feb.	39 76	37.32	Aug.	50.20	....

May	33.29	39.28	Nov.	32.51	....
June	30.72	40.26	Dec.	33.60	....

On August 25 tin was dull at 34 to 34.50 cents.

Ore producers and smelting companies will find U. S. Bureau of Mines Technical Paper 83, by Charles H. Fulton, entitled 'The Buying and Selling of Ores and Metallurgical Products' of value to them at this time of high and fluctuating metal prices.

The late president of the American Metal Co., Jacob Langeloth, who died August 14, 1914, left $5,528,413. He held shares in some of the largest metal concerns of the country.

Eastern Metal Market

New York, August 20.

The metals are lower in price, and the market is generally disappointing. The downward course of copper appears to be a further indication of the extent to which commerce is out of joint. Copper and steel are frequently said to move together, yet steel is mounting steadily to higher levels, while copper is steadily going down. The main cause of the situation, of course, is the paralysis of industry abroad, and another is the low rate of foreign exchange. In the past few days the value of the pound sterling has been down to $4.65, which makes buying here costly. Deliveries in all the metals are heavy, but new business is light. In zinc a little more life has been shown in the past few days, and the market steadied a little, but the trade is expecting the price to go below 10 cents at any time. There are some large war requirements to be covered sooner or later, but the brass-mills are supplied for the present, inasmuch as they bought heavily when contracts were booked. Lead has been inactive for the most part, but it is not expected that quotations will go much lower. Tin has been quiet without a break, and as for prices, the heavy arrivals of the month will keep them down. Aluminum maintains its strength, and therein stands alone among the metals.

Pig-iron has continued to advance in price; likewise finished and semi-finished steel. The munition plants continue to buy machinery, and the foreign demand for tools is so great that printing press manufacturers, makers of wood-working machinery, and others are now making engine-lathes. Toolbuilders generally are sold up to next year, and some until next June.

COPPER

The nominal quotation for electrolytic copper, August 20, was 16.25c. cash, New York. Reports were current that domestic consumers had taken, the day previous, 500,000 lb. at this price, but the sale was not confirmed, and reliable representatives of the trade said they doubted the propriety of giving publicity to such vague rumors. The weaker market here is largely a reflection of the state of the London market, where spot electrolytic was quoted August 19 at £80. The metal was quoted August 12 at £81, August 6 at £86 10s., and July 15 at £93 10s. In the past week second-hands have brought considerable pressure to sell; where the producers have stood with regard to price is more or less a matter of doubt. Some of them have held for 17c. cash, New York. Day after day the trade has been waiting for something to happen, just what they did not know, but nothing has transpired to break the monotonous quiet. Lake has been as dull as electrolytic, and it is rapidly approaching the latter's level. Some brands can be had at prices but a fraction above electrolytic, although prime brands are still quoted at 19 to 20c. Exports from the first of the month are unsatisfactory, as they total only 11,719 tons. They might be larger if American sellers would accept low prices, 16 to 16.12½c., for instance, but this they have so far been disinclined to do. An unquestioned influence back of the inactivity of the foreign market is the low rate of foreign exchange as before mentioned. As has been said, there are still large war order requirements to be covered, but these needs are not pressing, manufacturers having covered heavily when they booked the orders. Incidentally, with a declining market consumers are encouraged to hold off in buying. As usual, they will have to see the market going up before they will become active. Sheet copper is now quoted at 23c., base. A reduction of 1c. became effective August 19.

ZINC

For days the market has been dull to a point which properly might be called stagnant, although yesterday and today there has been some show of interest on the part of buyers, and a little better feeling. Yesterday the market was 11c., New York, and 10.75c., St. Louis. As with copper, it seems that the large makers of war munitions bought heavily when they secured their contracts. Nevertheless they must buy again, inasmuch as their war contracts have from two to three years to run. Incidentally new contracts for shells and ammunition are being placed, and others are pending. Inasmuch as the brass-mills are supposed to be filled to capacity for some time to come, it is a problem how the new demand for sheet-brass will be cared for, unless new rolling-mills are built, or old ones enlarged. Inquiries for cartridge-metal are bandied around and, seemingly, are nowhere welcome. Zinc at the present time is subject to so many counter influences that it is difficult to diagnose the market.

The very choice grades of zinc are still held at high prices, 35 to 40c. per lb., while ordinary brass-mill spelter can be had around 15c. With all the low prices, and the efforts to sell on the part of some, it remains a fact that some producers are comfortably sold up into next year. The exports August 1 to 21 total 3118 tons. Jobbers in galvanized sheets report that the demand for this product is poor; but it should improve with the lower cost of zinc and the improved demand for sheet, in turn, should help the sale of the metal. Galvanized pipe has been reduced, and likewise galvanized sheets. The latter, No. 28, is now quoted at 3.60c., mill.

LEAD

This metal is quoted at 4.45c. New York, by independents, and at 4.50c., by the leading interest, (the A. S. & R. Co.) The general opinion is that the bottom has been touched for the present. Last week the market sagged to 4.40c. New York (outside price), but since then there have been both inquiry and purchasing on the part of Russia, and a better tone has set in. Deliveries have continued at a heavy rate. The hope is that export sales will be resumed before long. The exports of the month, up to the 21st, totaled 1758 tons.

TIN

Since the buying of several hundred tons of futures, a couple of weeks ago, the market has been extremely quiet and uninteresting. There has been some interest shown in future positions which are attractive in price, the quotations of August 19 being 33c. for September and 32.65c. for October to January, but buyers are extremely slow about taking hold and definite inquiries are lacking. The quotation for spot August 19 was 33.75c. The deliveries for the month will be heavy. The arrivals up to August 21 totaled 3430 tons, and there was afloat on that day 4850 tons, most of which is scheduled to arrive in the month. London has slumped badly, and the trade there is discouraged. There is in Liverpool enough Bolivian tin ore to make over 4000 tons of refined tin. A good feature in America is an enormous demand from abroad for tin-plate. It has reached proportions which have compelled some of the mills to decline business, and is making a strong domestic market for plate.

ANTIMONY

In the past week there have been repeated efforts to sell antimony at reduced prices, but without much success. Russia is reported to have made various inquiries, but few or no sales have resulted and it is probable that that country will buy direct from China or Japan. Quotations are down to 31 to 32 cents.

ALUMINUM

Aluminum is firm at 33 to 35 cents.

Current Prices for Oils and Candles

(Corrected monthly by Standard Oil Co., California.)

All prices are f.o.b. San Francisco except where otherwise specified, and are subject to change without notice.

Granite Mining Candles.	Per set, cents.	Granite Mining Candles.	Per set, cents.
